Age.	Exposed to risk at each age.	Number who die within 10 years out of 1000 commencing at each age.		Exposed to risk at each age.	Number who die within 10 years out of 1000 commencing at each age.	
25	1287	45*	89	2137	35	47
30	1265	70	106	1867	46	60
35	1229	92	128	1565	61	78
40	1176	97	153	1252	83	102
45	1116	107	187	978	117	138
50	1062	146	235	684	122	190
55	997	186	300	417	—	—
60	908	237	392	180	—	—
65	743	343	512	—	—	—
70	470	451	652	—	—	—

* The table reads: Out of 1000 beginning at age 25 of cricketers born between 1800 and 1849, 45 die before reaching age 35, while 89 males E. L. T. No. 4, 35 cricketers born between 1850 and 1888, and 47 males E. L. T. No. 8 die within that 10 years. Similarly, out of 1000 beginning at age 30 the deaths between ages 30 and 40 number 70, 106, 46, and 60; and of 1000 beginning at age 35, 92, 128, 61, and 78 die before reaching age 45.

The comparisons show that cricketers form by no means a short-lived population, but on the contrary hold a substantial advantage at every age in both groups. This advantage is undoubtedly somewhat exaggerated for two reasons: (1) it is assumed that all cricketers are "exposed" from age 25, while in actual fact probably some do not "enter exposure" in first-class cricket till a later age; (2) a certain number of deaths very probably escape notice and are not recorded in the almanac. This would affect mainly the later age-groups, when after retirement from "active life" the cricketer may "drop into the grave, unpitied and unknown." Neither source of fallacy is, however, at all likely to be on a sufficient scale to alter the conclusion that cricketers are long-lived.

Gentlemen v. *Players.*

In Table II. comparison is made between "players" and "gentlemen," and it will be observed, except at age 25 when the difference is slightly in favour of the professionals, that the amateurs hold the advantage in longevity throughout.

TABLE II.—*Comparison of Amateurs and Professionals.*

Age.	Amateurs born between 1800 and 1874.		Professionals born between 1800 and 1874.	
	Exposed to risk at each age.	Number who die within 10 years out of 1000 commencing at each age.	Exposed to risk at each age.	Number who die within 10 years out of 1000 commencing at each age.
25	1705	40	993	36
30	1676	52	980	65
35	1637	63	957	99
40	1539	74	890	118
45	1328	99	766	130
50	1122	139	625	146

The suggestion is that the amateur not only shares with the professional the advantage of physical selection, but that he has in addition the benefit, as regards length of life, of social selection. His life, in general, runs in an easier groove. Glancing through the records given in "Wisden's Almanac" it is not difficult to see why, in this case, a superficial inspection should give rise to a belief in an unduly heavy mortality at the younger ages. The biographies relate to persons born during, roughly, the nineteenth century and (as shown in Table I.) nearly two-thirds of these births fall after 1850. Obviously, therefore, the deaths recorded must relate largely to the younger age-groups, since the greater number of the exposed to risk are still alive in 1913, the closing year of this study. In other words, relatively early in life they become "exits" and have not before 1913 had the chance of being recorded as deaths in the more advanced age-groups. Table I. shows clearly the process. Out of 2137 cricketers born between 1850 and 1888 and exposed at age 25, under half remain 20 years later and by age 60 all but 180 have gone. Their ranks are depleted by "exits" in the relatively early age-groups. The eye grasps the continual registration of deaths at the younger ages but fails to assess the effect of the "exits" in limiting the exposure in the more advanced years of life.

Summary.

1. There is a common belief that first-class athletes tend to die relatively young.

2. An examination of the available data shows that such a belief is not true for first-class cricketers, who are long-lived in comparison with the general population.

HOMICIDAL IMPULSE IN VERSE.

IN "Nan of Aviemore: A Highland Tragedy" (London: Erskine Macdonald, Ltd., 1927, pp. 67), Dr. A. Niven Robertson tells how Ian Grant left his beloved, Nan of Ruachar, to go to sea. His ship was wrecked, and he was struck on the head by a madman, his companion on a raft. Deprived of his reason, he wanders back to Ruachar in search of Nan, who has remained faithful to him although courted by a young doctor. Ian comes on the pair and shoots his supposed rival dead, but the shot also kills his sweetheart, and he dies in despair. The story is told in lively quatrains and the tragic lovers move to their fate against an ever-changing background of Highland scenery and life. The theme is the complete alteration of a man's character by an accidental blow, a natural catastrophe which, though inevitable, yet wrecks three lives, and every psychiatrist will be able to recall "surgical tragedies" of the same kind. The poem is full of the atmosphere, terrifying in its majestic loneliness and appealing in its primitive beauty, of the hills and scattered villages where its countrymen pursue their grim, unceasing struggle with Nature.

FRAUDS ON NURSING HOMES.

SENTENCE of nine months imprisonment passed at tl Marylebone police-court recently will protect the matro of nursing homes from a nuisance to which they have late been exposed. The accused, a man of 37, was stated have been liberated from prison on Sept. 14th and to ha gone to a nursing home under the influence of drink. H said he was a man of means and wanted the best atte tion for a fortnight in order to get the drink out of h system. He left next morning for the alleged purpose obtaining money at his bank and never returned. He appea to have incurred a debt of £23 to a cabman who drove hi about London. He was eventually driven to a nursing hor in Bayswater, where he made similar representatio Fortunately the matron happened to become aware of wh had occurred at the previous nursing home, and she co municated with the police, who arrested the accused in be The actual charge was that of obtaining credit to the exte of eight guineas at the two nursing homes by fraud.

The accused, in a long address to the magistrate, stat that he possessed a Jekyll-Hyde personality. When he w in a normal condition, he said, he loathed and despis himself for the disreputable things he did when under t influence of alcohol and drugs. The magistrate brie observed that it was a clever fraud and a mean trick, a passed sentence as already mentioned. The allegation of d personality was not further discussed, but was probab accepted as the familiar attitude of Philip sober towa Philip drunk. A detective-sergeant said that the accused h six previous convictions for fraud in the last three years

A GOOD INHALANT.

WE have received from the Pineoleum Co. (New Yo City) a simple and efficient type of nebuliser, intended use in the catarrhal conditions of nose and throat wh arise so frequently at this time of year. The composition the Pineoleum brand inhalant supplied with the nebuli is stated in the literature accompanying the apparat where it is claimed that careful and stringent standardisati both chemical and bacteriological, has ensured an absolut uniform product. The standardisation has been checked the Clinical Research Association, whose certificates sho definite inhibitory action of the inhalant on certain organis associated with respiratory catarrh. The present type nebuliser has been improved by making all the metal pa which are liable to contamination readily sterilisable boiling. The nebuliser delivers a copious and very fine sp of even distribution. The British agents and distributors Messrs. Brooks and Warburton (American Drug Supply C Ltd., 40, Lexington-street, London, W. 1.

TOXIC RUBBER.

Mr. W. E. J. G. de Bran writes to inquire whether medi practitioners have had brought to their notice cases sudden inflammation of the eyes among children for wh no reason can be found. The smarting and suffusion subs rapidly, the copious crying of smaller children seeming be the best remedy for them. Personal experience of his c leads him to suggest that such children will be found to h recently engaged in games with a hard rubber ball wh surface, probably through the medium of their fingers, come in contact with the eyes. He incurred just suc temporary inflammation himself after screwing a miniat rubber tyre called a "Meccano" into his eye, as a mono for the amusement of a small boy. Possibly some of readers may have some familiarity with the condition.

The toxic qualities of some rubber have been noticed many observers. In a letter published in THE LAN over 20 years ago (v. LANCET, June 10th, 1905) Dr. F. Pond drew attention to the presence of sulphide of antim as a constituent of red rubber and suggested the poss connexion of this with cases of intestinal disorder wh had come under his notice. Analyses made by THE LAN and in other laboratories had already demonstrated fact 20 years previously that rubber bands, washers, tubing contained this poisonous salt, but apparently negligible quantity, having regard to the length of t over which disintegration of the rubber was usually spr

RIFLE SHOOTING AS A PASTIME.

THE Society of Miniature Rifle Clubs has issued a st ment drawing attention to the advantages of rifle shoo as a pastime for medical men. Dr. C. Heygate Ver the King's Prize winner at Bisley, has, it is pointed set an example which is being followed by other mem of the profession, not only for the pleasure gained but as a means of training the eye to greater skill and judgm Among doctors who have won distinction as marks are mentioned Dr. P. G. Harvey, Dr. F. H. Kelly, and W. J. Bethune. It is suggested that any of our rea who are interested should apply to the Secretary of S.M.R.C. at 15, Arundel-street, Strand, London, for fur information.

Bradshaw Lecture

ON THE

PATHOLOGY OF PNEUMONIA.

Delivered at the Royal College of Physicians of London on Nov. 3rd, 1927,

BY JOHN F. GASKELL, M.D., D.P.H. CAMB.,

FELLOW OF THE COLLEGE; BEIT RESEARCH FELLOW; HONORARY ASSISTANT PHYSICIAN, ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

THE subject selected for my lecture has a stage which familiar to every member of the medical profession; the other hand, our knowledge of the complete hological processes of the disease is in many pects singularly inadequate. Although we are all miliar with that stage in the progress of a lobar umonia which occurs on the fifth to the seventh of the disease, just before the crisis, the oppor- ity seldom occurs to make a complete pathological mination of the earlier or later stages. The clinical dition, when such an opportunity does arise, has n so different from that of the same stage of an omplicated lobar pneumonia that the criticism ays can be made that the conditions found are comparable in the two cases. Further, we still k knowledge of the conditions which govern the ribution of pneumonic consolidation, why in one broncho-pneumonia is produced and in another ar pneumonia.

is therefore eminently desirable to endeavour to ain insight into the complete cycle of the pneumonic ess by experimental methods, not only with regard he phases of the struggle between the invading unism and the host, but also with regard to the litions necessary for that struggle to take place.

ertain results of experimental work [1] may perhaps pplied to the elucidation of the conditions found nan. In order to justify any such application necessary to show that the affinity between the ggle in the experimental host and in man is a e one. The results of the earlier experimenters from this point of view disappointing. It was vn soon after the discovery of the pneumococcus the introduction of this organism into the d stream or the peritoneal cavity gave rise to ges in the lungs, but these changes were so rent from those commonly met with in the human ect that few conclusions applicable to the latter d be rationally drawn from them.

troduction of the organism into the lung also unsatisfactory results, the lesions produced g of a broncho-pneumonic type scattered through- he lung, which threw little light upon the lobar of pneumococcal infection which is of particular est from the clinical point of view. The first advance in this matter was the production of pneumonia in dogs by Lamar and Meltzer.[2] nsufflation of the lung after intubation of the x they were able to produce lobar consolidation ly comparable in its pathological reaction to uman type.

eir experiments were confirmed and amplified he work of Blake and Cecil [3] on monkeys, who produced complete lobar consolidation by intra- eal injection. These experiments were all made pneumococci of very high virulence.

VIRULENCE.

any attempt to produce infective lesions by iment, estimation of the virulence of the infecting ism is of the utmost importance; this is ularly so in the case of the pneumococcus se its virulence varies so greatly.

e authors mentioned above used organisms which r the criterion that one-millionth of a c.cm. of 8-hour broth culture killed mice when injected peritoneally; their method of obtaining such a was by successive dilutions in broth. This criterion is open to objection that the few organisms injected lie in a comparatively large volume of a nutrient fluid which is not rapidly absorbed and in which they can freely multiply, the host acting as a living test-tube. The method, therefore, does not give an accurate measure of the minimal lethal dose to mice.

The virulence or pathogenic power of an organism depends upon two factors which cannot be measured separately—namely, the invading power of the organism and the resisting power of the host. In order to obtain any measure of virulence it is therefore necessary to standardise as far as possible one of these factors—namely, host resistance. The measure then used is the smallest dose of the organisms which will cause death. It is therefore essential to employ a method which ensures immediate reaction between the attacking organisms and the defences of the body. The organisms must be denied all facilities for multiplying other than those provided by the tissues of the host. Multiplication of the organism in the broth introduced will give a virulence value which is not only high, but which is also liable to considerable variation depending upon the rate of absorption of the fluid. The mouse is an experimental animal which is eminently suitable for the measurement of pneumococcal virulence, owing to its high susceptibility, and if healthy mice whose weight lies within narrow limits are used, a fairly satisfactory stabilisation of the host factor is obtained. The possibility of vitiation of the measurement of the dose of the organism by multiplication in the fluid introduced can be obviated by dilution in normal saline, which is rapidly absorbed. Such dilutions must, however, be injected immediately as the pneumococcus rapidly dies in saline solution.

TITRE.

My own experiments have been almost entirely carried out with a single strain of pneumococcus whose virulence has been altered at will. For convenience the measure of virulence or titre has been taken as the logarithm of the reciprocal of the minimal lethal dose—that is to say, the titre being x the minimal lethal dose is then $1/10^x$. The actual dose given can be roughly estimated from the fact that an 18-hours' broth culture contains between 200 and 500 million organisms, or otherwise 2×10^8 to 5×10^8. The minimal lethal dose at titre 7, therefore, lies between 20 and 50 cocci only and titre 8 becomes an absurdity.

The experimental animal selected was the rabbit, an animal moderately susceptible to the pneumococcus, which fortunately proved very comparable to the human host in its relationship to infection.

LUNG STRUCTURE.

Before describing the experimental lesions obtained I must first mention a point in the structure of the mammalian lung which is of considerable importance in the consideration of the probable origin of such lesions. The bronchial tree is lined with ciliated epithelium up to its terminal branches. These finally end in one or two terminal bronchioles having non-ciliated epithelium, each of which opens into an alveolar unit consisting of various portions which have been accurately described by Miller [4] and named by him on the analogy of a classical house, the vestibule, the atria, and air vesicles with terminal pouches or air cells. Owing to the absence of ciliation of these terminal bronchioles any material which reaches into or beyond them is not removed but is speedily sucked in by the respiratory movements and is bound to become spread through the whole system. Such a terminal bronchiole with its air spaces may be termed an alveolar unit, and any infection which reaches it necessarily involves the whole unit. These terminal units not only occur at the end of terminal branchings, but are also given off throughout the bronchial tree, rising from the largest bronchi, usually being in pairs, and connected to such a bronchus by only a very small short ciliated bronchiole. (Fig. 1). The central part of the lung is composed of such units which are thus

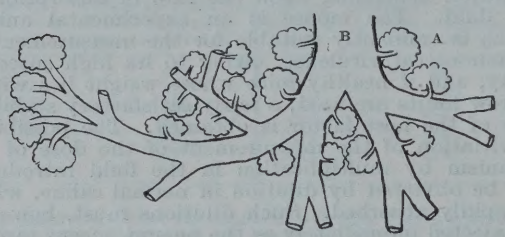
in very intimate connexion with the biggest bronchial tubes.

Owing to the respiratory to and fro current aided by the ciliary action of the epithelium, material lying in the large tubes is rapidly side-tracked into these central units. There is a great tendency for these small branchings consisting of a tiny bronchiole with two units attached to occur in whorls of three, a peculiarity of structure which explains the tri-lobed appearance of the consolidation not infrequently seen in broncho-pneumonic conditions.

EXPERIMENTAL METHOD.

The method employed in order to make certain of introducing pneumococci into the lung itself was to perform a tracheotomy and pass a soft rubber tube down the trachea as far as possible, the tube being of such size as to engage in the opening of the main bronchus to one lobe of the lung. The culture was then injected into the tube by piercing it with a fine injection needle. The material was then blown into

FIG. 1.



A diagram of the arrangement of the alveolar units round the larger bronchi. The alveolar units A arise directly from the largest bronchi B, and are thus in very intimate relationship with them.

the lung by means of a puff ball on the external end of the tube. It was found that by far the commonest site of any lesion produced was the lower lobe of the right lung, which is of interest because of the frequency with which this lobe is the site of pneumonia in man. The probable explanation in both cases lies in the fact that the bronchus of the right lower lobe is in the most direct line with the trachea.

By this method at least half of the culture injected is held to reach the lung itself, if, as became the rule, a volume of 1 c.cm. at least is injected. The loss, of course, occurs from material left behind in the tube and still adhering to its end when it is withdrawn. Infection of the tissues of the neck round the tracheal opening invariably occurred, but was of little moment, the wound healing rapidly in two to three days.

Over 80 experiments were performed with the Type I. pneumococcus, whose virulence varied from a titre of below 3 to one between 6 and 7. The nature of the lesion obtained was found to depend entirely upon the virulence of the organism used and not upon the dose given. This had already been indicated by the results obtained by Lamar and Meltzer.[2]

LESIONS PRODUCED.

Introduction of cultures into the lung with titre of below 4 produced only the most insignificant changes or none at all. With titre between 4 and 5 patchy lesions were produced which could be closely compared with human broncho-pneumonic lesions; with a titre of about 5 lesions of larger size were obtained, reaching from the centre of the lobe to the periphery, thus corresponding to a lobular distribution; with titres between 5 and 6 the whole lobe became involved and either a definite lobar pneumonia was obtained or the infection spread still further, involving all the thoracic serous cavities and giving rise to a double pleurisy and pericarditis. With a titre of 6 or over an entirely different type of lesion was produced with diffuse changes throughout all lobes of both lungs. This could be shown to be due to a rapid intense septicæmic invasion of the blo stream, and was comparable with the type of lesi obtained as the result of intravenous or intraperiton injection. It may therefore be called the septicær type of lesion or, on the analogy of tubercul infection, miliary pneumonia (see table).

Titre.	M.L.D. mouse.	Lesion rabbit.	Distribution.	Reaction.	Mini effec do
3–4	$1/10^3$	Broncho-pneumonia.	(*a*) Central; (*b*) Diffuse.	Catarrhal.	0·1

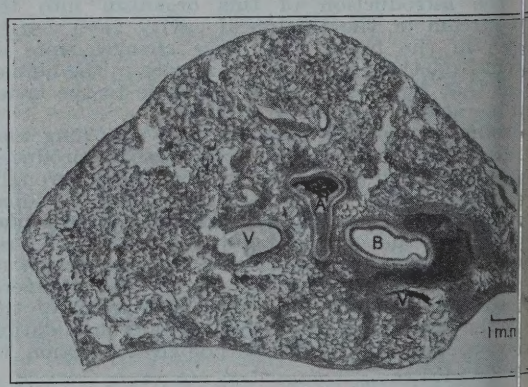
6–7	$1/10^6$	Septicæmic.	Fulminating.	Serum and R.B.C.	0·(

I will now describe the histological char observed in each of these different types and the same time suggest a possible explanation of t variation with rise of virulence. I will for the mom neglect the method of disposal of organisms wh titre is below 4.

BRONCHO-PNEUMONIA.

When organisms of about titre 4 are introdu into the rabbit's lung, they and the material in wh they are introduced are speedily side-tracked by respiratory current and ciliary movement into nearest alveolar units. Frequently in my experim the material has only reached the larger bronchi has, therefore, been side-tracked into the cer units in connexion with them, thus giving rise patchy central pneumonia (Fig. 2); if the mat has spread more widely a diffuse broncho-pneum is produced (Fig. 3). The inflammatory reaction w takes place remains confined to the units thus inva which are often in the earlier stages clearly deline by the consolidated area. Very few polymor nuclear leucocytes come out into the area of inf mation, the exudate consists mainly of a serous in which large cells with round or oval nuclei ponderate, having all the characteristics of alv

FIG. 2.



Rabbit. Central broncho-pneumonia. A localised centra of consolidation surrounds the main bronchus (B) fo thirds of its circumference. A = artery, V = vein, B = bron This figure and those following are drawn from a photo of a cross section of the right lower lobe. The consol area shows up dark.

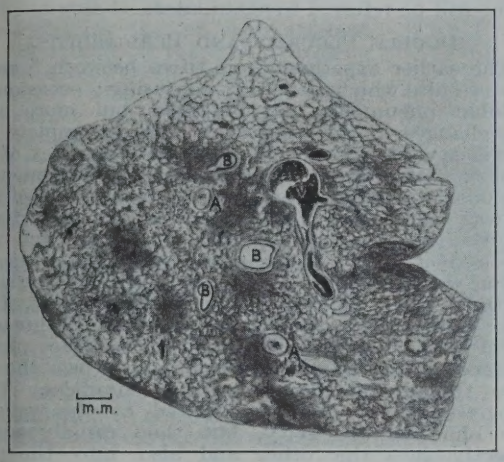
lining cells; the cells which are first cast off ra undergo fatty degeneration. It is only in the stages that cocci in any quantity can be identifi such a lesion. They appear to have little pow multiplication and to be rapidly destroyed b inflammatory reaction, though, as will be ment shortly, this destruction is not always complete.

Later the neighbouring alveoli begin to take in the inflammatory action so that the unit o becomes obscured. This peripheral reaction is a

erile and consists of a greater or less amount of rous exudate with an intense proliferation of the veolar lining cells, which often produce plaques of gh epithelium so that the alveoli appear completely led with large cells producing the catarrhal reaction hich has been claimed to be characteristic of true oncho-pneumonia.

The capillaries of the consolidated patch become ore and more engorged, reaching a maximum at out the fourth or fifth day. They then gradually come more inconspicuous and are often difficult to

FIG. 3.



bbit. Broncho-pneumonia. Scattered patches of consolidation re widespread, tending to group round central structures of obe. Arteries tightly contracted. Lettering in Figs. 3, 4, 5, 6 s in Fig. 2.

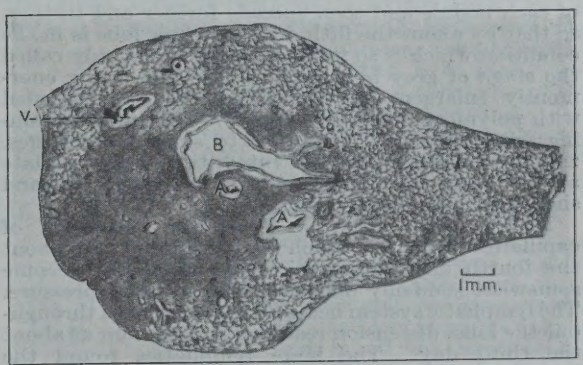
d on the seventh day. In the meantime the more id exudate becomes slowly absorbed by the local phatics; the cells thrown off earliest become integrated and the catarrhal increase spreads into patch owing to the activities of the alveolar cells l remaining in situ, which are endeavouring to lothe the damaged alveolar surface. These newly med cells are continually being cast off, and at out the seventh day the consolidated nodule almost irely consists of such cells and is almost entirely n-vascular. The process of absorption by the phatics is shown by a mild dilatation with a ly intense aggregation of lymphocytes which y form regular perivascular cuffs round the small eries in the patch.

One of the most striking characteristics of this low de type of reaction is the complete absence of nge in the bronchi and bronchioles, with the eption of the presence of exuded alveolar exudate the small bronchiole of the patch and sometimes the bronchus around its opening. With a lesion this grade the animal often shows little sign of comfort except for a transient rise of temperature the first two or three days, slight distaste for food, perhaps a little fall in weight. In a few experiments a second period of malaise has occurred on the h to seventh day. On killing the animal during s period, evidence of the occurrence of fresh lesions been found, in which cocci have been identified, ugh they are not longer to be found in the original ons. The reaction has been similar to that usually be found on the second or third day. These eriments throw light on that low grade form of ncho-pneumonia which occurs in children, charcsed by the successive appearance of fresh patches lung infection which may even continue for as g as six months, Armstrong.[5] The explanation t they suggest is that the local defensive reaction he original lesions has not been sufficiently intense pletely to destroy the invading cocci. The material ruded from the small bronchiole thus contains ng cocci which, in the endeavour of the bronchus to cleanse itself, are carried to fresh alveolar units into which they get side-tracked and there set up a fresh focus of infection. This would be especially liable to happen where patches of central consolidation existed whose tiny bronchioles open into the larger air tubes.

LOBULAR PNEUMONIA.

As the virulence titre of the invading organism is increased, though the initial states of the cleansing of the bronchi and the side-tracking of the infecting material are the same, the inflammatory reaction produced becomes both more extensive and more intense in nature. The power of the cocci rapidly to reproduce themselves is increased, so that they are much more easily found in the earlier stages, and are no longer confined by the limits of the alveolar unit, but spread directly into others lying around it. The nature of the inflammatory reaction is changed owing to an increase of the numbers of polymorphonuclear leucocytes and consequently a diminution in the preponderance of the larger alveolar cells. The serous exudate is increased and fibrin may begin to be formed in it. The capillaries again become more and more engorged up to about the fourth day, but then, especially in the centre of the patch, they become rapidly obliterated by the pressure of the exudate in the alveoli which are now not merely filled but widely distended by it. Though in the earlier stages the polymorphonuclear exudate is already beginning to take place, serum and desquamated alveolar cells, which are often fatty, at first predominate. It is during this early period that cocci are most conspicuous. Though the inflammatory patch has become much larger, its periphery is still similar to that of the smaller patch with catarrhal exudate taking place at a fairly early stage. These patches may become so large that they coalesce and thus form the more extensive lobular type of lesion (Fig. 4). At all stages, however, the original foci can be identified by the more intense nature of their reaction and by definite zoning round them. As has been already mentioned, the lobular lesions tended to occur with a titre of about 5. The bronchioles in the affected

FIG. 4.



Rabbit. Lobular pneumonia. Large area of consolidation extends from central bronchus to pleura (over which is dry pleurisy) with a smaller patch on opposite side. Vein (v) shows peri vascular infiltration.

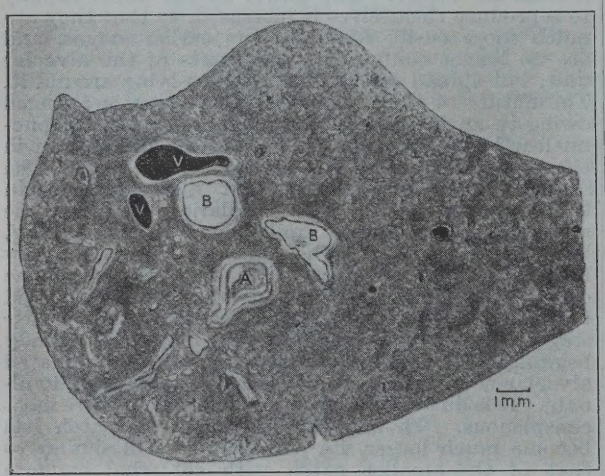
area now begin to show changes, losing their epithelium and often becoming difficult to distinguish from the surrounding consolidation. The intensity of the process of the removal of exudate by the lymphatic channels also increases so that the larger lymphatics round the larger vessels become conspicuous, being dilated with serum and débris. The perivascular lymphatic reaction which occurs in the later stages also increases in intensity.

LOBAR PNEUMONIA.

With a further rise of titre to a value of between 5 and 6, if a suitable dose is introduced, a lobar lesion is obtained (Fig. 5). The organisms have now a

much greater power of reproduction and invasion and spread rapidly throughout the lobe, being apparently able to keep in advance of the host's attempt to localise them by inflammatory reaction until the periphery of the lobe is reached. A lobar lesion 24 hours old shows the process clearly. Reaction is then still patchy and most intense at the centre of each patch, but the patches are rapidly coalescing by the junction of their peripheries where the exudate s almost entirely serous. It is in this peripheral serous

FIG. 5.



Rabbit. Lobar pneumonia. General consolidation of whole lobe except for a few atria. The lighter zone of perivascular infiltration is becoming conspicuous; epithelium of larger bronchi still intact.

exudate that by far the largest and most vigorous cocci are to be found. They are lanceolate in shape and stain deeply, while at the centre of the patch they are already beginning to be destroyed, being small, rounded, and often poorly staining. Polymorphonuclear reaction is now becoming intense at the centre of each nodule and soon spreads further and further, so that by about the fifth day the whole lobe is in the condition which is so familiar and is commonly called the stage of grey hepatisation, the lobe being enormously enlarged and the alveoli widely distended with polymorphonuclear exudate. By suitable staining with Sudan III. in order to show fat changes, zoning can still be demonstrated, the earlier exudate at the central foci being the more degenerate and showing greater fatty changes.

In this lobar form of lesion the distension of capillaries does not reach its maximum till about the fourth day, after which the capillaries become somewhat suddenly obliterated by alveolar pressure. The lymphatic system becomes widely dilated throughout the lobe, distension reaching a maximum at about the third day. The large lymphatics round the larger vessels are then extremely conspicuous, being often nearly as wide as the lumen of the blood-vessel itself. The bronchi and the bronchioles are now widely involved. Their epithelium becomes desquamated, they are filled with exudate, and merged into the general consolidation. These bronchial changes, however, occur later than those of the surrounding alveoli, and therefore appear to be secondary and not primary.

As has already been mentioned, cocci are most conspicuous at the spreading edge in the earliest stages. They can easily be found up to the third day, they are much more difficult to find on the fourth day, and by the fifth day they have practically disappeared. Attempts have been made to study the methods by which they have been dealt with, and two processes appear to take place during these earlier stages. The first of these is their destruction extracellularly in the alveoli; cocci tend to become agglutinated into little clumps, they stain more and more indistinctl their staining portion becomes smaller and small till finally they disappear. The second process is phagocytosis by polymorphonuclear cells, certa individuals of which become crowded with coc These tend to aggregate round the vessels and pe vascular lymphatics and have also been found the lymphatic channels and in the peripheral sinus of the lymph nodes. Others have been found in t lumen of blood-vessels. These appearances sugg that certain polymorphonuclear cells after becomi filled with cocci leave the inflammatory area eith by returning to the blood stream or by passing the lymphatic channels to the lymph glands. Th point will be referred to again later.

DOUBLE PLEURISY AND PERICARDITIS.

The earlier experiments at titres between 5 and gave results which were very confusing; occasiona a lobar pneumonia was obtained, but more oft the changes in the lung itself were incomplete a a widespread invasion of the serous cavities of t thorax took place. More accurate measurement the dose of culture given gave the explanation of th It was found that if the dose was too large doul pleurisy and pericarditis was produced, but wi the correct dose a lobar pneumonia. Both types lesion were produced by suitable dilution of a sin culture. The explanation appears to be that, if t dose is too large, the rapid spread of the invadi cocci can no longer be limited by the pleu surface of the lobe, but cocci rapidly pass throu into the pleural cavity in great numbers. Th progress still cannot be limited by the walls the one pleural cavity, but they rapidly spre directly into the other and also into the pe cardium. The reason why the changes in t original lobe do not assume the proportions fou in lobar pneumonia is probably due to a lack of sup of sufficient polymorphonuclear leucocytes. Su enormous numbers are poured out into the th serous cavities that not enough are left to produc true lobar distension. The pressure of the pleu exudates also tends to inhibit the filling of the lo A lesion of this type, though apparently so seve does not by any means always cause the death of t animal. If the latter survives to the sixth or seven day, cultures from all three serous cavities are usua sterile; the invasion, though so widespread, has b successfully dealt with.

MILIARY OR SEPTICÆMIC PHENOMENA.

In many experiments at this titre the animal d not, however, survive. A septicæmic invasion of blood occurs and proves rapidly fatal, whether lesion is lobar in type or takes the form of dou pleurisy and pericarditis. The lesions characteris of the septicæmic or miliary type have been descril by M'Gowan and M'Neil [6] in very fatal epidem which broke out amongst boys in certain reformat schools. The characteristic pathological finding was intense septicæmic invasion of the blood stream the pneumococcus. Their sections were shown to Pathological Society of Great Britain and Ireland 1914. The lesions consisted of a patchy serous exud into the alveoli, accompanied by desquamation alveolar cells and often by small hæmorrhages wit complete absence of any polymorphonuclear reacti but intense engorgement of capillaries and ot vessels of the lung.

This description applies equally well to the c ditions experimentally produced in rabbits by eit the introduction into the lung of pneumococci extreme virulence, titre 6–7, or the intravenous intraperitoneal injection of cocci sufficiently virul to kill the animal. (Fig. 6.) The condition has been described by Armstrong and myself [7]; it alm always occurs in small children and is extremely fa death taking place within 48 hours. It probably occ sporadically throughout the country. From the descr tions given, certain of Blake and Cecil's [8] experime in monkeys also produced lesions which appear to h been of this type, death taking place early, with diff

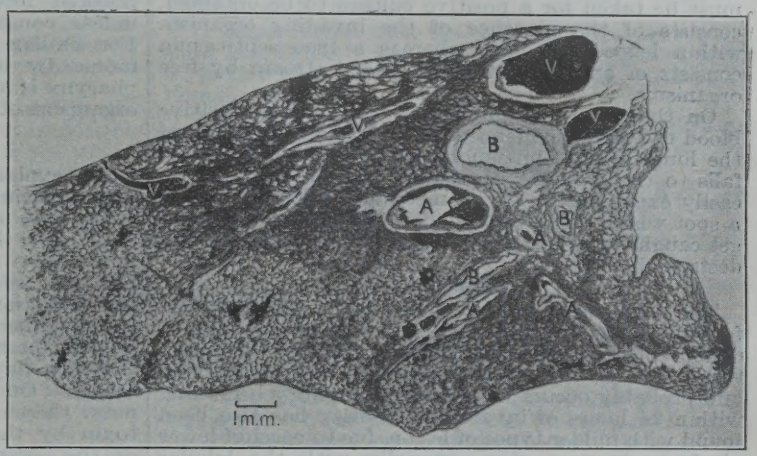
hanges throughout all lobes of the lung. They consider hese cases to be merely extreme early examples of lobar neumonia, but it must be remembered that changes f virulence were not accurately controlled in their xperiments, so that the titre may well have been at imes sufficiently high to produce a septicæmic lesion. Changes of this type are usually present in the ther lobes of the lung when septicæmia intervenes in lobar pneumonia. Even when the itre is above 6, so that the septicæmic ision is produced with extreme apidity, the site of the original invaon can still be identified by a lesion emonstrating that an early attempt as been made by the host to destroy . The alveoli at the original foci are istended with polymorphonuclear ells which have been extruded in ie earliest stages of invasion and ave even been successful in locally estroying the pneumococci. The ntrast between the almost complete sence of cocci in these small foci d the immense numbers which varm throughout the rest of the ng is very remarkable. There thus pears to be a critical time depending, any rate partly, upon the power of pid reproduction of the coccus, when e general defences of the body beme completely paralysed and a fulminating" condition arises in ich the bacteria can riot unopposed.

LYMPHATIC DRAINAGE.

In a few experiments at the lobar re another system became inlved with extremely fatal results. ention has already been made of the great distension the lymphatics of the lung in the earlier stages the more severe but still localised types of lesion. ough the lymphatic channels contain all sorts of bris which must have been derived from the alveoli the lung, free cocci are, as a rule, completely sent, only an occasional polymorphonuclear cell ntains them, and the contrast is great between the e lymph channel and the alveoli next to it, in which cocci are numerous. Occasionally an intense asion of the whole lymphatic system has taken ce and the picture is reversed. Extremely large, ply staining, lanceolate diplococci swarm through- the lymphatic channels and show up much more spicuously than the cocci in the alveoli, which small and poorly staining. There thus appears be usually a great power of resistance to invasion appertaining to the lymphatic system, even in its smallest channels. A critical point can, however, be reached with a sufficiently virulent organism, when this resistance completely breaks down, just as is the case with the blood stream.

These results are, perhaps, of wider and more general application. They indicate that the swelling of the lymph gland, which belongs to any inflamed tissue, is usually caused by débris drained from the part affected, which is in itself sterile, except for the presence of organisms which, as a rule, are safely enclosed in leucocytes and become filtered out in the peripheral sinuses of the lymph gland. Such organisms are mostly killed by the leucocytes; if all are destroyed the gland subsides without breaking down, but if some are successful in destroying their host the gland then suppurates. Occasionally, however, an infection is of such virulence that the power of resistance of the peripheral lymphatics becomes destroyed. The lymphatic system draining the part undergoes a true invasion and an acute lymphangitis takes place.

FIG. 6.



Rabbit. Miliary pneumonia (septicæmic). Small hæmorrhages widely scattered, a specially large one (H¹) just below the largest artery, above and to the left of which is an incomplete serous œdema filling the more central alveoli. Arteries and veins engorged, bronchi intact. The hæmorrhages H are shown on the accompanying tracing (6A).

FIG. 6A.

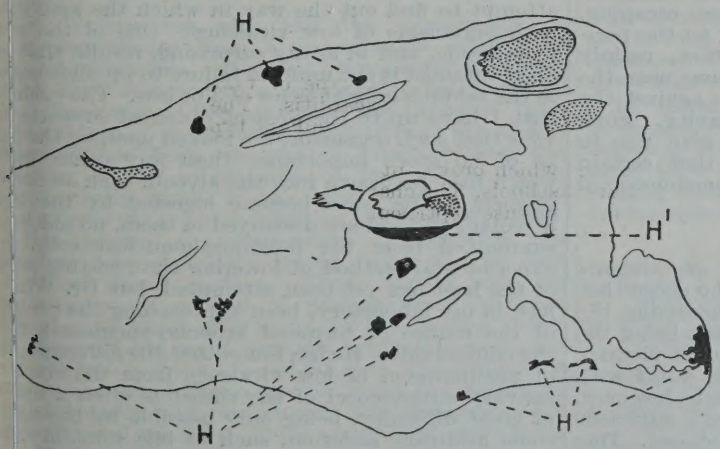


Diagram of Fig. 6 showing the hæmorrhages (H).

INVASION OF THE BLOOD STREAM.

I have also arrived at a similar view with regard to the presence of cocci in the blood stream. Throughout these experiments blood cultures have always been made at whatever stage the animal is killed, and in all the more severe forms of lesion blood films have been examined. In all experiments where definite lesions have been obtained and the animal has been killed on the first or second day, blood cultures have been positive. By the fifth or sixth day, even when the lesion is severe, the blood culture has almost always been sterile. Thus organisms are always present in the blood at the earlier stages.

In order to be found in film they must, of course, be present in very considerable numbers. By methods of dilution, &c., I have endeavoured to correlate the findings in film and culture, and have found, when culture methods show that cocci are sufficiently numerous to make it reasonable to expect to find them in film, that first, all cocci found are within leucocytes; and secondly, that the numbers found in film are much greater than culture methods would indicate. It is only when counts begin to reach values

of 500,000 to 1,000,000 cocci per c.cm. that free pairs begin to appear in film. This would indicate that in the blood stream also the invasion is not a true one when the virulence of the organism is below a certain value, but that all organisms present are contained within leucocytes. The disproportion in count and film would mean that the great majority of such enclosed cocci are non-viable. The suggestion can therefore be made that a bacteriæmia, which is so commonly present in the earlier stages of many diseases and in which considerable quantities of blood must be taken for a positive culture to be obtained, consists of the presence of the invading organism within leucocytes only, whereas a true septicæmia consists of an invasion of the blood stream by free organisms.

On this line of argument the value of a positive blood culture as evidence that the path of invasion of the lung in lobar pneumonia is by the blood stream falls to the ground. Metastatic foci of infection are easily explained by it. A metastatic focus is merely a spot where a bacterium-laden leucocyte happens to get caught up when the bacteria gain the victory and destroy the host.

PLEURISY.

The relationship of pleurisy to lung lesion has been found to vary very considerably. The intense form of double pleurisy and pericarditis which occurs with titres of high virulence has already been described, and probably occurs with extreme rapidity beginning within 24 hours of invasion. Pleurisy has also been found with milder types of lesion due to cocci of lower virulence in connexion especially with the lobular type of lesion. In its mildest degree it consists of a patch situated over a lobular lesion which has just reached the surface; the patch then has been found to be sterile at all stages. When the lung lesion is larger, the pleurisy, though local, is sometimes infected, but usually when this takes place the whole pleural cavity soon becomes involved and considerable effusion takes place. A lobar lesion has also been obtained accompanied by unilateral pleurisy with effusion. The evidence tends to show that such lesions, restricted to one pleural cavity, take place some time after the initial invasion and that cocci persist in them after they have been destroyed in the lung.

PERICARDITIS.

In a few experiments the pericardium alone has become infected, both pleural cavities escaping. The relationship of the root of the lung to the pericardium is very close, and an infection, mainly localised to the central region of the lung near the root, can reach the surface where it lies against the pericardium and directly invade this cavity. Such pericarditis, if recovered from, would give rise to adherent pericardium, which suggests that certain cases of this condition may arise from a pneumococcal infection by way of the lung.

MINIMAL EFFICIENT DOSE.

I have already mentioned that my experiments confirm those of Lamar and Meltzer,[2] who claim that the type of lesion does not alter by increasing the dose; the exception which proves this rule being the production of lobar pneumonia and double pleurisy and pericarditis at the same titre. One point with regard to the dose introduced into the lung is, however, most important; at any particular titre a sufficient dose must be given or no lesion will be produced. This minimal dose diminishes rapidly with rise of titre (see table). Its value at titre 4 is approximately 1/10 c.cm. and at titre 5 1/100 c.cm. and at titre 6 1/1000 c.cm. It therefore follows that in nature it is much easier for an organism of high titre to infect the lung. This perhaps throws light upon the rarity of pneumococcal broncho-pneumonic lesions in adult man; the defences of the pulmonary system and its cleansing power are so great that it is almost impossible for an organism of a virulence such as should produce broncho-pneumonia to make good any invasion. Only when the host defences are destroyed by some such process as a severe cerebral lesion can sufficien material obtain entry. An experiment of Lamar an Meltzer bears upon this point. They found tha by cutting the left vagus they could produce lesion in a dog's lung with doses which, in the intact anima had no effect.

In experimental work it is most important to u a method which will introduce the culture right in the lobe of the lung. The cleansing power of t trachea is enormous, and the experimental resul are quite uncertain if the culture is, for instanc injected into the trachea just below the laryn unless comparatively enormous volumes are use For similar reasons, any attempt to produce pne monia by introduction of cultures into the nas pharynx is almost bound to fail unless large doses organisms of extremely high virulence are introduce

CRISIS.

An explanation of the remarkable phenomen which occurs in lobar pneumonia, known as t crisis, may now be attempted. I have already stat that cocci have practically disappeared from t lung on the fifth day, but are usually easy to find the more severe lesions until then. Now, the ch toxin of the pneumococcus is an endotoxin whi is only liberated when the cocci are killed. The is thus an increasing liberation of endotoxin up the fifth day, but after that the supply practica ceases. One of the factors determining the cri may, therefore, be the final neutralisation of en toxin by the defences of the body 48 hours la on the seventh day. Another extremely interesti phenomenon has been demonstrated by Armstron He has shown that in lobar pneumonia the protect power of the serum, which is extremely slight at t onset of the disease, practically vanishes after 24 ho and remains absent for the first four days. On t fifth day it suddenly reappears and increases en mously and with great rapidity to a maximum on t seventh or eighth day. It then slowly diminis throughout convalescence. The rapid rise of t power to destroy pneumococci coincides with crisis. The combination of these two processes th affords some explanation of the regularity with wh crisis occurs on or about the seventh day.

LOW VIRULENCE ORGANISMS: TERMINAL PNEUMON

Investigations are also being pursued in order attempt to find out the way in which the lung de with organisms of low virulence. One of the m remarkable, and in a way surprising, results that been obtained is the uniform failure to produce lesi in the rabbit's lung at titres of 3 or less. The evide that I have up to the present obtained supports view that such organisms are looked upon by the h as of no more importance than any other déb which may be drawn into the alveoli, such as car pigment. The cocci become ingested by the la alveolar cells and are destroyed in them, no aid be summoned from the polymorphonuclear cells. experimental method of lowering the resisting po of the host has yet been attempted, but Dr. Whi has, in my laboratory, been approaching the prob of the nature of terminal broncho-pneumonia fr the clinical side. He has found that the differentiat of pneumococci of low virulence from the comm salivary streptococci of the throat is often a ma of great difficulty, being only possible by the us some arbitrary criterion, such as bile solubility, criterion which he has finally fixed upon. He also found that using this criterion, many term pneumonias appear to be due to salivary streptoc and not to pneumococci. The true pneumoco of low titre is more frequently found in such condit as chronic bronchitis. He is inclined to believe the statement that over half the dwellers in our la cities have pneumococci in their throats is an erron one, due to the inclusion of many salivary stre cocci among the pneumococci identified. I h performed a few experiments with streptococci, have been able to produce lesions in the ra

n all respects similar to those produced by pneumo-occi. It is thus possible that many terminal pneu-nonias are streptococcal in origin, not pneumococcal.

OTHER TYPES OF PNEUMOCOCCUS.

All the work hitherto described has been done with he single strain of Type I. pneumococcus. I have een endeavouring to reproduce the results with rains representing Type II., Type III., and the nagglutinable Group IV. With the latter, which as obtained in pure culture from a case of penoph-nalmitis and had a titre of 5, the range of lesions roduced with the Type I. organism have been fairly curately reproduced; the titre of the organisms quired to produce any lesion such as double pleurisy nd pericarditis is, however, slightly lower than that ecessary in the case of Type I.

Unexpected difficulty was found with the Type II. nd Type III. organisms. Not only was it impossible raise them to a titre higher than 5 by mouse assage, but even when at their highest titre it was npossible to kill rabbits by intraperitoneal injection, hich can be done with certainty with the Type I. ganism. At this titre the most extensive lesion at could be obtained in the rabbit's lung was of bular type, and the lesions were on the whole of lower grade than those of Type I. at a corresponding re. These organisms thus appear to have a lower thogenic power both to mice and rabbits, and, these experiments can be applied to the case of man infections, it would help to explain the great evalence of Type I. organisms in the more severe ng lesions.

Dr. Whittle has also been attempting to correlate e titre of organisms obtained from human lung sions with the experiments I have described. He s found, in agreement with other observers, that r far the greater number of pneumococci associated th severe human lesions are of Type I., and that very close correspondence can be shown to exist tween human and experimental rabbit lesions at y particular titre, lobar lesions in man being sociated with titres from 5 to 7 and broncho-eumonic lesions with titres below 5. With lesions low grade, where the titre of the organism is also v, Type I. is comparatively uncommon. In order make the analogy closer we have introduced a mber of these organisms into rabbits' lungs and have tained a close correspondence in each experiment the human lesion from which the strain was tained.

Dr. Whittle has also had the opportunity of amining strains from a considerable number of ses of pneumonia, extending over nearly two years, hich have occurred in a somewhat isolated village ar Cambridge; the outbreak has therefore been the nature of an epidemic. The titre of the strains overed has been remarkably constant, and the mbers of the inhabitants of this village, being mparatively small, it has been possible to draw a scheme of the paths infection has probably taken. I this instance a pneumococcus of high titre has erefore been definitely traced from case to case actual direct contact. These results open up prospect of control of pneumococcal infection so far as lobar pneumonia in the healthy adult concerned, and point very strongly to the necessity the isolation of this type of disease. The occurrence pneumococci of titre 5 or over in the human throat undoubtedly very uncommon; the organisms with eumococcal reactions, which are present, are almost ays of quite low titre.

SUMMARY.

My endeavour in this lecture has been to put before y certain experimental facts which can, I think, legitimately applied to man. They show that the e of the infecting organism is all important, and that s determines both whether a lesion will be produced all and what the nature of that lesion will be. bar pneumonia in the healthy adult is due to anisms of titres between 5 and 7, which are otherwise comparatively rare. The deduction may be made that it is spread by direct contact infection passing from throat to throat, though very possibly intermediate carriers are often concerned. I must apologise for having concentrated mainly on my own work, and for not having attempted any comprehensive review of the literature of the subject and the value of the work of many other observers, so I hope you will forgive me for perhaps dwelling overmuch upon the details of experiments which have been my chief interest for the last seven years.

The following is a summary of conclusions which I think can be made.

1. Experiments with the pneumococcus on rabbits show a sufficiently close analogy to its effects on man to justify the application of the results obtained to human disease.

2. The estimation of the virulence of the infecting organism is of the utmost importance. The virulence titre can be conveniently measured in mice.

3. Organisms whose titre is below 3 have no pathogenic value in the healthy host.

4. Organisms of titre 4 produce broncho-pneumonic lesions.

5. Organisms of titres between 4 and 5 produce lobular lesions.

6. Organisms of titres between 5 and 6 produce either: (1) lobar pneumonia, or (2) general infection of the thoracic serous cavities.

7. Organisms of titres between 6 and 7 produce either: (1) lobar lesions, which become septicæmic; or (2) the septicæmic or miliary lesion.

8. The septicæmic lesion is the form always produced by a true blood infection.

9. If a lesion is produced a temporary bacteriæmia always occurs in the early stages.

10. An effective dose diminishing with rise of titre must reach the lobe of the lung for a lesion to be produced.

11. The lymphatic system is as a rule sterile, except for organisms enclosed in leucocytes, while engaged in draining away the débris of the inflammatory reaction produced.

12. Any breakdown of this protective power causes a true lymphangitis and makes the prognosis very grave.

13. The reaction in broncho-pneumonia is often of a grade insufficient to completely destroy invading organisms, some of which escape into the bronchi and are carried to other parts of the lung producing fresh foci of infection. This gives an explanation of relapsing broncho-pneumonia.

14. Lobar pneumonia in the healthy adult is due to organisms of titres between 5 and 7 which are otherwise comparatively rare. The deduction may be made that it is spread by direct contact, infection passing from throat to throat, though very possibly intermediate carriers are often concerned.

MINOT-MURPHY LIVER DIET IN ADDISONIAN ANÆMIA:

REPORT OF TWO CASES.

BY JOHN H. ANDERSON, C.M.G., C.B.E., M.D. MELB.,
AND
E. I. SPRIGGS, M.D., F.R.C.P. LOND.,
RUTHIN CASTLE.

Addisonian anæmia calls for Heraclean courage on the part of the physician. Any measure, therefore, which helps in the fight against this disease is worthy of consideration and wide trial. Minot and Murphy [1 5] in America have described a diet which has given good results in their hands, the improvement lasting in certain cases as long as three and a half years, which is the length of time the treatment has been in use. Briefly, they give large amounts of mammalian liver, cooked and raw, with plenty of vegetables and fresh fruit, but little fat.

The method was brought to our notice by a letter from a former dietitian at Ruthin Castle who accepted a post in the Massachusetts General Hospital, Boston, and to whom fell the duty of administering the diet in a number of Dr. Minot's cases. This lady has published a paper setting forth the diet tables and cookery which had been found most useful.[2]

Two cases were then treated on these lines at Ruthin Castle, and the results are set out below.

CASE 1.—Male, aged 49. Two great-aunts died from Addisonian anæmia. Three years ago had sore tongue, breathlessness on stairs, and pain in left side; treated with hydrochloric acid and improved. Two years ago pallor and loss of energy and strength; slight exertion caused palpitation and breathlessness. Red count 1,800,000

* Blood transfusion.
† Minot-Murphy diet begun. v.f. = Very few.

Recovered with arsenic, rest, and fresh air. Six months before admission, pallor, dyspnœa, and weakness returned and did not yield to treatment so readily. Admitted Ruthin Castle, May 19th, 1927. Lemon yellow colour, pale conjunctivæ, weak, sore tongue, palpitation and breathlessness on least exertion, confined to bed. Blood hæmoglobin 40 per cent., red cells 1,160,000, white cells 2000, no nucleated red cells, but megalocytes, macrocytes, microcytes and poikilocytes present. Fractional test-meal showed achylia. Patient was treated with rest, fresh air, arsenic injections, and acid drink by mouth, but went steadily down hill. Transfusion of citrated blood produced only slight temporary improvement, and in view of a severe reaction (rigor, temperature 105° F., pulse 160, cyanosis and disorientation) was not repeated. On June 27th feeding with liver was commenced, and within a few days the patient felt better and her blood condition improved, as is seen in Table I. The figures are represented graphically in Fig. 1.

Present condition (Sept. 3rd).—Good colour, appetite normal, no breathlessness, can walk upstairs two steps at a time, and is back at work. There is occasional tingling of the fingers and the tongue is a little sore at times.

CASE 2.—Female, aged 63, no known anæmia or subacute combined degeneration in family. Twelve months ago began to get easily tired, sore tongue, made sick by food, breathless, palpitation. Bed ever since, treated with iron and arsenic in various forms. Admitted Ruthin Castle July 26th, 1927, lemon coloured, pale conjunctivæ. Circulatory system: Soft systolic bruit at apex, extrasystoles every five–six beats. Blood: Hæmoglobin 31 per cent., red cells 1,200,000, and white cells 2200; colour index 1·3, nucleated red cells, macrocytes, microcytes, and poikilocytes present. The average red cells were normal in size but many were elongated (a point stressed by Prof. van den Bergh at the recent meeting of the British Medical Associati

eathlessness or palpitation, tongue not sore, heart iet and regular.

Fig. 3. is included for comparison, as it shows the e of improvement of the blood in a case which l well with transfusions. This case was reported one of us recently.[3]

It is obvious that, although the blood began to over within a few days of giving the diet, we may in each case be dealing with a remission. We have, however, seen many remissions in this disease, and are of opinion that these patients have improved more definitely and rapidly than is usual. Further, Case 1, a medical man, had already had the experience of three remissions, and he has no doubt that his recent improvement has a character of its own.

In the belief that the diet has given valuable help to these patients, we make this communication with the object of encouraging a wider trial.

A full account of the régime, with typical diets, is given by Miss E. A. Nicholls in the paper referred to above, and by Miss Thelma Tubbs and Miss Elizabeth Bellinger.[4]

The dietetic treatment may be summarised as follows:—

Mammalian liver essential: Calves', beef, pigs', from 90 to 240 g. (3 to 8 oz. cooked weight) daily.

Encourage: 1. Kidneys. 2. Chicken livers. 3. Red meat (without the fat)—beef, lamb, mutton, calves' or ox heart. 4. Fruits (fresh, tinned or dried, up to 12 oz. a day): Oranges, grapefruit, raisins (steam until soft before serving), prunes, strawberries, peaches, apricots, or pineapple, 5. Vegetables (cooked or raw): Lettuce, cabbage, spinach, tomatoes, asparagus, or other vegetables.

Permit: One egg, milk (half a pint), tea, cocoa. Toasted wholemeal bread, plain biscuits. Potatoes, macaroni, cereals. Sugar not to exceed 20 g. (⅔ oz.) a day. Pickles, relishes, salt, and vinegar. Poultry. Fish. Shell-fish.

Avoid: Fats, not to exceed 70 g. (2½ oz.) a day. Bacon, pork. Butter. Cream. Cheese. Oils, olive oil in dressings, &c. Nuts.

In our patients the liver was taken in the following forms: Lightly roasted, almost raw in sandwiches, underdone in soup, and as a cream. Two full days' diets are set out hereunder:—

Diet I.—Breakfast: Fruit juice; porridge; boiled egg; toast, butter, marmalade; coffee, milk.

11 a.m.: Raw beef and liver sandwiches.

Lunch: Fried liver, onion, and tomatoes; macaroni; spinach; salad; fresh fruit; toast.

Tea: Biscuit; jam; fruit; fruit salad and raisins.

Dinner: Vegetable soup with scraped raw liver; underdone chop or steak or liver; rice pudding with raisins; orange salad or fruit.

Diet II.—Breakfast: Fruit; porridge; toast, butter; coffee, milk.

Lunch: Fried liver; tomato, onion; green vegetables; rice pudding with raisins; stewed fruit; toast, butter, milk.

Tea: Biscuits; jam; fruit; tea and milk.

Dinner: Vegetable soup with raw scraped liver; fish; meat or liver dish; green vegetables; milk pudding; stewed or fresh fruit.

Our thanks are due to Mr. J. G. S. Jeffery, B.Sc., and Mr. A. J. Leigh, B.Sc., who made the blood estimations.

HEALTH MINISTER'S VISIT TO LANCASHIRE.—Mr. Neville Chamberlain recently visited some of the principal institutions administered by the Manchester Corporation. He said he believed in seeing the great centres of local government for the sake of getting into touch with local administration and feeling, and so that the administrators of local government might themselves understand what he was endeavouring to bring about. He also inspected the District Council's housing scheme at Ormskirk, and cut the first sod of the £30,000 sewage scheme of the West Lancashire Rural District Council at Maghull, near Liverpool. Speaking at Ormskirk on the reorganisation of Poor-law institutions, he said that there were thousands of beds empty in these buildings, whilst there were queues of people waiting to get into voluntary hospitals. What was needed was a reorganisation of the institutions under the guardians and those belonging to the municipalities.

BLOOD TRANSFUSION IN SPRUE.

BY G. CARMICHAEL LOW, M.D. EDIN., F.R.C.P. LOND.,
SENIOR PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES, LONDON, AND SEAMEN'S HOSPITAL, ROYAL ALBERT DOCKS; CONSULTING PHYSICIAN FOR TROPICAL DISEASES, TILBURY HOSPITAL;
AND
W. E. COOKE, F.R.C.S. IREL., D.P.H.,
MEDICAL SUPERINTENDENT, HOSPITAL FOR TROPICAL DISEASES.

IN the later stage of sprue a blood picture very like that seen in pernicious anæmia often develops. This hæmolytic type of the disease is very dangerous and often fatal.

A detailed account of the blood in such cases was given by one of us (G. C. L.) as long ago as 1912.[1] It was there pointed out that in the later stages it might be practically impossible to differentiate the blood picture of sprue anæmia from that of true pernicious anæmia. On this picture some have argued a relationship between the two diseases, or even their identity, but sprue is a definite entity with a symptomatology and pathology of its own and is not pernicious anæmia.

Transfusions of whole blood have been used for some time in pernicious anæmia, septicæmia, loss of blood from hæmorrhage, often with very beneficial results, and recently a patient suffering from the hæmolytic type of sprue was transfused with whole blood just before coming to us. Under our treatment the sprue improved and he apparently completely recovered, but after leaving us and living at home for some time he relapsed and again developed a very severe type of anæmia. We therefore took him back into the Hospital for Tropical Diseases and, his wife being a suitable donor, her blood was used for the transfusion.

A Short Résumé of the Cases.

CASE 1.—European male, aged 58. Residence abroad, India and Mesopotamia. Previous illnesses: enteric fever, 1888; dysentery, 1890 and 1895.

Sprue began in 1917, with light-coloured stools and sore tongue, and persisted in spite of various methods of treatment. During this time patient was residing in Canada and England. By 1923 the disease had so progressed that the patient was admitted to a general hospital in England, his blood count reading: red cells 600,000, hæmoglobin 22 per cent. Three whole blood transfusions performed during a period of 27 days resulted in a rise of the red cells to 800,000, hæmoglobin 27 per cent. Four months later the count read: red cells 1,460,000, hæmoglobin 56 per cent.

When transferred to the Hospital for Tropical Diseases, London, on April 10th, 1924, he was still very ill and wasted. Weight 6 st. 12 lb., and the blood count was red cells 2,440,000, hæmoglobin 65 per cent. With our usual line of treatment he improved so much that he was able to leave hospital on August 1st, 1924, his weight having risen to 11 st. 1 lb., and the count to red cells 4,160,000, hæmoglobin 80 per cent.

During the following two years the patient returned to hospital twice for short periods of treatment, his blood having, on the occasion of the first readmission, fallen to red cells 2,000,000 and hæmoglobin 60 per cent., but on each occasion the anæmia responded to treatment.

On July 7th, 1926, the blood count had fallen to red cells 3,000,000 and hæmoglobin 75 per cent.; poikilocytosis and nucleated red cells were present, but after readmission to hospital on that date the decline continued in spite of the usual methods of treatment, until August 6th, 1926, when it was decided to transfuse with blood in the hope of checking it. The count on that day was red cells 2,300,000 and hæmoglobin 65 per cent.

The wife acting as donor, 700 c.cm. of whole blood were given by the citrate method. No rigor occurred, but the transfusion was followed by a rise of temperature to 100° F. Three days later a further decline had taken place, the count reading red cells 2,000,000, hæmoglobin 65 per cent., and a trace of albumin was found in the urine. By Sept. 7th following—that is, a month later—the red cells totalled 4,200,000 and hæmoglobin was 80 per cent., and the patient was discharged in the following week with a count of 4,700,000 red cells and 85 per cent. hæmoglobin, feeling much better in every way. He has reported at intervals since his discharge and was keeping well up to September, 1927.

[1] Jour. of Trop. Med. and Hyg., 1912, xv., 129.

An even more striking case is the following:—

CASE 2.—Mr. X., an old case of sprue, who had never been very anæmic, went home to Scotland. Apparently he relapsed there and rapidly deteriorated, his blood count falling and his general condition becoming alarming. It was then decided, though the risk was considerable, to bring him to London, where he arrived on the morning of Oct. 2nd, 1926.

Previous Illnesses.—Malaria and dysentery, 1888; syphilis and gonorrhœa, 1891; hepatitis, 1902; cholera, 1917. Ptomaine poisoning, 1919. Had lived in India and New Zealand.

Present Illness.—In 1920 diarrhœa began, with light-coloured stools, sore tongue, and loss of weight, the onset of sprue, so in 1921 he returned to England.

On Dec. 8th, 1922, patient was admitted to the Hospital for Tropical Diseases, after seeing one of us, and he had to return to hospital on five subsequent occasions. On each of these he responded to treatment for the sprue with varying success, and when in hospital the specific infection was treated with potassium iodide, N.A.B., and bismuth. On May 20th, 1926, he was discharged from hospital to spend the summer in Scotland, his red cells numbering 4,500,000, hæmoglobin 85 per cent.; weight 13 st. 12 lb.

The following September (1926) he relapsed so rapidly that on Oct. 1st the task of bringing him from Scotland to London was one of considerable difficulty and risk. For three days before the commencement of the journey he had been vomiting continuously and was only conscious at intervals. His medical attendant (Dr. W. Telfer, of Greenock) and nurse must be commended for their success in bringing a patient in such a critical condition safely through such a long journey by train.

On his arrival at the Hospital for Tropical Diseases at 8.45 A.M. on Oct. 2nd in an unconscious condition 10 oz. of 5 per cent. glucose saline solution were at once administered intravenously. The blood count on admission was: red cells 940,000, hæmoglobin 20 per cent. As no return to consciousness or marked improvement followed the glucose injection, it was decided to transfuse with whole blood, and at 2.15 P.M. 730 c.cm. of citrated blood was given. The effect was dramatic. As the patient's colour improved he regained consciousness, recognised doctor and sister, and was talking naturally before the transfusion was finished.

At 3.45 P.M. the patient asked for some Benger's food and no vomiting followed. The transfusion was followed at 4.15 P.M. by a rigor and a rise of temperature to 102° F. at 6 P.M., falling to 98° F. at 11 P.M. The following day he had so much improved that it was difficult to imagine he had been so ill on arrival. The temperature rose again (102° F.), and after swinging for the next few days gradually reached normal. There was no more vomiting and the diet was gradually extended.

On Oct. 4th, two days later, the red cells were 1,000,000 and the hæmoglobin 25 per cent. On Oct. 10th the red cells were 2,130,000 and the hæmoglobin 50 per cent., and thereafter the improvement was steadily maintained.

On Feb. 10th, 1927, the patient had picked up from his wasted condition. Seventeen days after admission his weight had been 12 st. 7 lb., and by the date of discharge had reached 14 st. 2 lb. At the same time the blood showed 5,240,000 red cells and 95 per cent. of hæmoglobin. Up to the time of writing he has had no relapse.

The following, a somewhat similar case, is also interesting.

CASE 3.—European male, aged 67. Residence in India for 43 years. Family history good, no asthma. Previous illnesses: measles, mumps, varicella, enteric fever (at 14 years), malaria; no definite history of dysentery.

In 1920 diarrhœa commenced with flatulent dyspepsia and was diagnosed as colitis. Improvement occurred on return to England on holiday, but on the voyage to India again in 1925 the diarrhœa recommenced, and for the year previous to admission to the Hospital for Tropical Diseases the stools had been white and bulky.

On entering hospital on July 5th, 1927, he was very wasted and anæmic, and his tongue was glazed and flabby and sore. the abdominal wall was wasted, but the abdomen was not distended; the liver was slightly diminished and he showed a typical picture of severe sprue. Blood count on admission was red cells 2,540,000, hæmoglobin 65 per cent.; weight 7 st. 3 lb. Urinary analysis: specific gravity 1010, otherwise normal. Wassermann negative. No ova or protozoa in stools.

As he did not progress under the usual treatment, and on four days later it was found that the red cell count had fallen to 2,020,000, it was decided to transfuse with whole blood.

The patient was found to belong to group III., a suitable donor was procured, and on July 12th, 1927, the patient's serum was tested against the donor's blood and no incompatibility was noted. The citrate method was used

with all the usual precautions, the blood being given by the needle and funnel method into the right cephalic vein. Transfusion was started at 2.30 P.M. and at once symptoms of hæmolysis and anaphylaxis manifested themselves. The needle was at once withdrawn, not more than 5 c.cm. having been given. The symptoms, in order of appearance, were: coughing, nausea, flushing; coldness of the skin, which became clammy, cyanosis of lips, vomiting, pulse accelerated but regular and feeble, severe pain in lumbar region; diarrhœa and shivering. The diarrhœa and shivering persisted at intervals till 5 P.M. At 6 P.M. the temperature had risen to 102° F., but by then his condition had improved. The following morning he was much better, he had had some sleep during the night, and was able to take fluids. No micturition occurred till 5.30, an interval of 26½ hours after the commencement of the transfusion, and then he passed 5 oz. of smoky urine containing albumin, a few red blood cells, hæmoglobin, and both blood and hyaline casts. He continued to make satisfactory progress. Six days later: red cells 2,200,000, hæmoglobin 65 per cent., albumin and granular casts present. Ten days later: red cells 3,040,000, hæmoglobin 70 per cent. Twenty-one days later: red cells 3,840,000, hæmoglobin 75 per cent., albumin, no casts. Forty-one days later: red cells 4,460,000, hæmoglobin 85 per cent., albumin, faint trace. The weight was 7 st. 13 lb., a gain of 10 lb., and he was able to walk a little in the ward. His progress is still satisfactory.

Case 1 is interesting as showing how useful transfusion can be in the most advanced cases. A red count of 600,000 with 22 per cent. hæmoglobin indicates a condition from which few could hope to recover. After the transfusions the patient kept well until three years later, when another transfusion became necessary. Up to the present this patient maintains satisfactory health (one year later). Three years is the longest period that has elapsed since transfusion in any of our sprue cases, but there is reason to expect that some of our later cases may recover completely, and require no further transfusions.

Case 2 is an example of the dramatic effect sometimes attained by transfusion. The rapid recovery from unconsciousness and the subsequent steady improvement greatly impressed all who saw the case, and convinced them that transfusion is essential in all such severe cases.

Case 3 presents many features of interest, the chief being: (1) the occurrence of the hæmolytic and anaphylactic symptoms, although no incompatibility was noticed when the bloods were previously tested; (2) the rapid recovery from the sprue condition though so small an amount of blood had been injected.

Conclusions.

Blood transfusion has now been established as a most important method of treatment in sprue. It would appear that the amount of blood given is not the important factor, though in cases like No. 1, where the patient's blood had fallen to a dangerously low level, a large amount of fresh blood would undoubtedly be a distinct benefit. The important factor seems to be that the blood injected stimulates the blood-forming tissues of the body. How this takes place is a matter for further investigation, but the blood seems to act in somewhat the same manner as do proteins injected in "protein shock" treatment.

In patients who have sustained a slight rigor or pyrexia following transfusion, the beneficent results appear to be as good and perhaps even more rapid than their appearance than in those cases where no rigor or pyrexia has appeared.

Cases of hæmolysis or anaphylaxis are fortunately rare. Case 1 had no symptoms, although the second transfusion, given three years after the first, might have caused them. Case 3 gave no history of previous injection of serum or protein and had no asthmatic history, and yet such severe symptoms occurred that life was only preserved by the prompt recognition of the onset of anaphylaxis and hæmolysis and immediate cessation of the transfusion.

As regards the treatment of sprue generally, several points of interest may be mentioned: first, the use of liver extracts in the form of liver soup; and secondly, the use of the so-called pulvis bataviæ. Recently Dr. George Minot, of Boston, in an address delivered before the American physicians, claimed that liver, and especially a fractional alcoholic extract thereof, is a specific in the treatment of pernicious anæmia. In the discussion that followed Dr. Bailey K. Ashford pointed out its remarkable efficacy in the treatment of the so-called "pernicious anæmias" of sprue. The use of liver in sprue goes back for 30 years or more. Castellani states that it is an old native remedy in Ceylon. It was extensively used by Sir Patrick Manson, and one of us (G. C. L.) has also used it for the last 20 years in an extensive practice of this disease. Though no very startling results can be claimed for it, it does seem to do good, and there is no reason why it should not, as the liver is shrunken in sprue and very probably does not secrete properly. We may, then, by giving liver extracts, supplement this deficiency.

Batavia powder is a specially prepared organic compound of lime, with traces of iron and manganese. It contains no vegetable matter. It is the ancient "Peter Sys's cure," which was used extensively in Singapore in the old days. Originally supposed to come from cuttle-fish bones, it is now prepared from ordinary lime and is a proprietary preparation still. It may act by supplementing the deficiency of lime which is present in the disease, but it also seems to act beneficially in controlling the diarrhœa. It may be given in 1 drachm doses twice or three times a day and continued until the stool becomes solid and well formed. It seems to have a real use in the treatment of the disease.

PERNICIOUS ANÆMIA,

WITH SPECIAL REFERENCE TO *BACILLUS WELCHII* AS THE CAUSAL AGENT.*

BY STANLEY DAVIDSON, B.A. CAMB., M.D., F.R.C.P. EDIN.

(*From the Department of Bacteriology, University of Edinburgh.*)

IN 1888 William Hunter[1] published in THE LANCET his famous paper, in which he stated that pernicious anæmia was caused by a toxin elaborated in the intestine. Since then numerous theories have been advanced as to the cause of this disease, but the question is still unanswered to-day. In view of the recent revival of interest in Germany and America in the intestinal toxin theory, it would seem desirable to review briefly the arguments in its favour.

(1) *Clinical Signs.*—Starting at the oral end of the alimentary tract with sore tongue and gastric achylia and ending at the rectum with the discharge of peculiar chrome-coloured fæces, we have evidence of an abnormal condition of the gastro-intestinal tract.

(2) *Pathological Findings.*—As far back as 1860 Flint[2] noted changes in the mucous membrane of the stomach. These have been confirmed by Fenwick,[3] Osler,[4] and many other workers. Similar organic changes have been described more recently in the wall of the small intestine.

(3) *Bacteriological Findings.*—The abnormality of the flora found throughout the whole length of the gastro-intestinal tract supports this theory. Bacteriological evidence will be found later in this paper.

(4) *Evidence of a Chronic Intoxication.*—Moench, Kahn, and Torrey[5] state: "The qualitative effect on the blood and blood-forming organs, the symmetrical cord lesions, the degenerative atrophy of the mucous membrane of both stomach and small intestine, the endotheliolytic manifestations, all without conspicuous loss of weight, seem to be evidence of some undiscovered toxic agent assailing continuously and over a long period of time tissues which give rise to symptoms only when seriously and irreparably

* The work here recorded was done under the auspices of the Medical Research Council. The report was read in substance at the meeting of the British Medical Association at Edinburgh, July, 1927.

damaged. The vagueness of the history of early pernicious anæmia, characteristically a syndrome of increasing listlessness, indefinite nervous symptoms, complaints occurring in fourth and fifth decade, and in association with achylia, has been observed often enough in the early course of the disease to suggest pernicious anæmia, even without the characteristic blood changes. An onset of this character out of which the features of pernicious anæmia eventually emerge in itself suggests a toxic influence, unremitting and of extreme chronicity, to which the body reacts ineffectually."

The possibility that an undiscovered specific intestinal organism may be the causal agent has induced many workers in the past to make most careful qualitative examinations of the intestinal contents of persons suffering from pernicious anæmia. These efforts have always failed. In my opinion, this was to be expected, because I believe that chronic intoxication from the intestinal tract is the result, not of any unknown organisms, but of an abnormal situation and excessive numbers of organisms normally found in any healthy intestine.

In order to test this hypothesis I have elaborated a technique by means of which an actual quantitative estimation of the main groups of intestinal flora in a sample of fæces can be obtained. As this work is being published elsewhere, no details of the method will be given in this paper.

Quantitative Estimation of the Intestinal Flora.

A comparison of the intestinal flora of cases of pernicious anæmia and healthy subjects, if made qualitatively, would yield no information of value, since in both cases *Bacillus coli*, streptococci, and *Bacillus welchii* are found. When a quantitative examination is made, valuable information is forthcoming. Comparing the fæces of 30 cases of pernicious anæmia, with 33 samples from healthy persons, I found on the average that in pernicious anæmia the streptococci are increased from 100 to 1000-fold, the *B. coli* from 1000 to 10,000-fold, and the *B. welchii* from 100,000 to 1,000,000-fold. These results fully confirm the findings of Moench, Kahn, and Torrey.

This non-proteolytic fermentative flora, containing a very high proportion of viable organisms, is typical, and found in every case of pernicious anæmia.

Bacteriology of the Small Intestine.

I believe that this flora is found in the small intestine, and that the absorption of toxin takes place at this situation. We must remember that absorption is at its greatest in the small bowel, and would be correspondingly increased if the mucous membrane was damaged. Furthermore, the hydrogen-ion concentration is at the optimum for the production of "Welch" toxin, and in actual practice I find the *B. welchii* to be mainly in the vegetative and not in the spore stage in this situation.

It is impossible to examine the ileal contents in cases of pernicious anæmia, but for the following reasons it seems fair to assume that this abnormal flora exists in this situation. From examination of the total intestinal tracts of animals we find that, starting from a sterile duodenum, we reach the lower ileum where streptococci and moderate numbers of *B. coli* and *B. welchii* are found. In the colon these organisms are far more numerous. The greater the number found in the colon, the greater the number in the ileum. This has been confirmed by me on human beings at operations of the small intestine.

Examination of the stomach and duodenum in cases of pernicious anæmia shows an abnormal flora; the contents, instead of being sterile, show great numbers of organisms normally found only in the lower ileum and colon—i.e., streptococci and *B. coli*, sometimes one and sometimes the other predominating. These findings have been repeatedly confirmed, and are probably the result of achylia.

Van der Reis,[6] in 1922, by a special apparatus examined the contents of the small intestine in 19 cases of pernicious anæmia, and reports an invasion of organisms which are normally found only in the colon. Finally, Seyderhelm,[7] in order to confirm these findings, established an ileostomy in ten cases of pernicious anæmia, and reports that a brown fluid was evacuated which could not be distinguished from stool in appearance, odour, or bacterial content. It may safely be concluded, therefore, that from the stomach to the rectum there exists in pernicious anæmia a great quantitative increase of streptococci, *B. coli*, and *B. welchii*.

The Causal Organism.

Whether the intoxication is the result of all three organisms or of one particular organism is still unsettled. William Hunter believed the streptococcus to be the cause. Many workers blame the colon bacillus. Dr. A. F. Hurst, in his remarks at the meeting of the British Medical Association at Edinburgh in July, held both responsible, and dismissed *B. welchii* as having nothing to do with the condition. Herter, Moench, Kahn, and Torrey, and others, including myself, believe that the Welch bacillus is the most probable causal organism, for the following reasons:—

(1) While all these groups are greatly increased in numbers, *B. welchii* shows by far the largest increase.

(2) *B. welchii* is one of the most powerful hæmolytic agents known. The streptococcus found in pernicious anæmia, as well as in healthy subjects, is an enterococcus, and is never, in my experience, hæmolytic. The same applies to the colon bacilli. The majority are non-hæmolytic, while some show a weak hæmolytic action quite incomparable to that of *B. welchii*.

(3) On experimental evidence.

(*a*) B. S. Cornell injected[10] sublethal doses of *B. welchii* into the tip of the spleen of rabbits, and produced in every case an anæmia varying from a mild chronic condition to a very acute severe anæmia. The anæmia was similar in every way to that found in pernicious anæmia. The injection of hæmolytic streptococci or *B. coli* failed to produce an anæmia.

(*b*) Kahn and Torrey[8] injected monkeys intravenously with Welch toxin, and produced all the blood changes which are considered typical of pernicious anæmia. After three weeks the monkey developed complete antitoxic immunity, further injection of toxin failing to produce any anæmia.

(*c*) Kahn and Torrey,[9] in order to overcome this immunity, gave monkeys Welch toxin by the mouth and found that the toxin was either destroyed or not absorbed through the normal mucous membrane. Accordingly they damaged the mucous membrane of the stomach of the monkeys with sodium fluoride and fed the monkeys through a stomach-tube with 20 c.cm. of fluid culture of *B. welchii* at weekly intervals. A very severe anæmia resulted, indistinguishable from pernicious anæmia. Moreover, no immunity resulted when the culture was given via the stomach. This is a very important point, and may explain the lack of reaction on the part of the tissues of patients suffering from pernicious anæmia.

The *B. welchii* produces a true exotoxin and hæmolysin. A qualitative examination of 30 different strains of *B. welchii* by Dr. J. M. Alston and myself both by the fermentation method of Simonds and by hæmolytic tests, shows that *B. welchii* from normal intestines and animals does not differ from *B. welchii* isolated from cases of pernicious anæmia. I agree with Moench, Kahn, and Torrey that if a Welch bacillus is the cause of pernicious anæmia, it is so not because it differs qualitatively from other Welch bacilli, but because of the great increase in numbers.

It is now well recognised by clinicians that the finding of achlorhydria is essential before a diagnosis of pernicious anæmia can be made. It has, however, never been settled whether the achlorhydria is produced by the factors which cause pernicious anæmia or whether it is the primary ætiological factor itself. I am in favour of the latter view, since it is well recognised that a proportion of achlorhydric

atients after many years develop pernicious anæmia; per cent. of apparently healthy individuals have en shown to have a complete lack of hydrochloric id in their stomachs, and yet only a very small action ever develop pernicious anæmia. Achlor-dric patients may continued for years or throughout e in reasonable health, provided that the liver is stroying the toxins absorbed from the small estine. As soon as the liver begins to fail, a chronic ain of symptoms is produced which, after many ars, may develop into pernicious anæmia.

Summary.

1. Clinical symptoms and pathological findings pport the view that pernicious anæmia is caused an absorption of toxin from the intestinal tract.

2. A bacteriological examination of both small d large intestine shows a non-proteolytic fermenta-e flora which is typical for pernicious anæmia. qualitative examination shows the organism to be ilar to those found in health. A quantitative amination shows an enormous increase of viable anisms, particularly in regard to *B. welchii*.

3. Biological and experimental evidence points to *B. welchii* as the most probable causal agent.

Conclusion.

Weighty evidence has accumulated that pernicious emia is due to the absorption of a toxin from the estinal tract, and the possibility that the *B. welchii* he ætiological agent is well worthy of the further estigations which are proceeding in this laboratory.

THE LOCAL ORIGIN OF THE INCREASED BACTERICIDAL POWER OF THE BLOOD FOLLOWING ULTRA-VIOLET IRRADIATION OF THE SKIN.

By ALBERT EIDINOW, M.B., B.S. LOND., M.R.C.S. ENG.

(*From the National Institute for Medical Research.*)

It has been shown that irradiation of the skin with ra-violet rays increases the bactericidal power of th blood.[1] The conclusions from these experiments n cated that the optimum bactericidal response was ob ined by the application of the minimal erythema do e of light, and with irradiation of a surface area of kin equivalent to 20–30 sq. cm. per kg. weight.[2] Si e the blood of the general circulation increased its ba ericidal properties after irradiation of the skin, a eries of experiments was designed to determine wh ther this phenomenon originated at the site of irr diation, or whether it was due to some secondary re tion of the whole organism. Two series of experi-m its were carried out, so as to examine at the same tim the blood circulating through the area of irr diated skin and the blood of the general circulation. Th skin of the hind limb of the cat and the skin of the rabbit's ear were selected as having a blood-supply which could be readily isolated.

Irradiation of the Skin of the Hind Limb of the Cat.

It has been shown that irradiation of the abdominal skin of the cat with a quartz mercury-vapour lamp increases the bactericidal power of the shed defibrinated blood tested in vitro.[3] A similar experiment was carried out, but in this case the skin of the hind limb of a cat was irradiated. The result of this experiment can be followed from the following table :—

TABLE I.—*Average per cent. Hæmobactericidal Power of Sample of Sterile Defibrinated Blood collected from the Jugular Vein of a Cat and Tested with a Culture of Staphylococci.*

		Per cent.
(1) Before shaving right hind limb		74
(2) After shaving right hind limb		66
(3) ½ hour	after irradiation of limb with the M.V.L. for 15 min.	85
(4) 1 ,,		84
(5) 1½ hours		88
(6) 2 ,,		93
(7) 2½ ,,		93

A similar series of experiments were carried out with the hind limb tightly ligatured, so as to arrest the circulation directly after irradiation. No increase in the bactericidal power of the blood samples collected from the jugular vein was observed. The result of this experiment indicates that the increased bactericidal power following irradiation of the skin must be due to changes which develop with the circulation of the blood through the irradiated area. Experiments were therefore carried out to examine the blood which was flowing through the irradiated limb. A cat was anæsthetised with ether, and the hair of the hind limbs was shaved and the common femoral arteries and veins were dissected out. Excluding these vessels, each limb was tightly ligatured, so that blood was only entering the limb from the artery and returning by the vein. The right and left femoral veins were temporarily clamped so that blood samples could be collected, and a sample was taken from the jugular vein. The skin of the left hind limb was then irradiated with a mercury-vapour lamp (200 volts D.C., K.B.B. type) for 15 minutes, and at intervals blood samples were again collected from each of the veins. The bactericidal power of all the blood samples were tested against staphylococci in the usual way. The blood flowing through the irradiated limb had an increased bactericidal power after irradiation, while the blood samples from the non-irradiated limb and the jugular vein were unchanged.

* Right femoral vein (non-irradiated limb).
† Left femoral vein (irradiated limb.)

This experiment (Table II.) shows that the blood returning from the "irradiated limb" has an increased bactericidal power compared with the blood in the jugular vein and in the control limb which was treated in the same way, except that the skin was not irradiated.

Hæmobactericidal Changes following Irradiation of the Rabbit's Ear.

The hair was removed from the ear of a rabbit two days prior to each experiment by means of a depilatory (barium sulphide). Blood samples were collected from the lateral ear veins of both ears, and the inner and

outer surfaces of the right ear were then exposed to a mercury-vapour lamp, 6 in. distant, each surface for ten minutes. Blood samples were again collected from each ear at intervals after irradiation, and the bactericidal power of the blood samples collected were examined in the usual way. The results of these experiments showed that (1) the blood samples obtained from the irradiated ear had a higher bactericidal power than those from the non-irradiated ear; (2) the blood from the irradiated ear showed an increased bactericidal power in a shorter time than the "control" ear.

As a variation of this experiment (Table III.), the right ear of a rabbit was irradiated and clamped at its base directly afterwards. Blood samples were collected from the left ear vein before and after the right ear was irradiated. The bactericidal power of all the blood samples tested remained unchanged during the whole experiment.

In another series of experiments the blood-supply to the ears was isolated so that the blood flowing through the ear and returning by the lateral veins of each ear could be examined. A rabbit was anæsthetised by intraperitoneal injection of urethrane. The central artery and veins of each ear were dissected, the central vein was ligatured, and a clamp was placed on the artery. By releasing the clamp on the artery samples of the blood flowing through each ear were obtained when required. The skin of the left ear was exposed to a mercury-vapour lamp, 8 in. distant, for 20 minutes. The animal was kept in the hot room at 37° C., as it was noticed that the ears otherwise became cold. Blood samples were collected from the irradiated and non-irradiated ears, and the bactericidal power of each sample was tested by the usual method. The result of these experiments can be followed by reference to Table IV.

TABLE IV.—*Average per cent. Hæmobactericidal Power (tested with Staphylococci) of—*

	Samples of blood collected from lateral vein of— Irrad. ear.	Non-irrad. ear.
Before irradiation	35%	38%
5 min. after irradiation ..	49%	34%
45 „ „ ..	90%	25%
55 „ „ ..	87%	38%
100 „ „ ..	71%	46%
180 „ „ ..	94%	47%

The results of these experiments indicate that when the skin is exposed to sources of ultra-violet rays a bactericidal effect is produced in the blood at the site of irradiation, and this is carried to the general circulation. Repeated experiments have given constant results. It has not been possible to isolate a definite substance with bactericidal power.

All experiments carried out in vitro with irradiated skin have so far failed to demonstrate a substance which will on injection into an animal increase the bactericidal action of the blood. There are, however, many observations which support the view that the irradiated skin is more resistant than normal skin to the inoculation of micro-organisms and to toxins (i.e., vaccinia, &c.).

Conclusion.

The results of these experiments indicate that the erythema dose of light applied to an area of skin increases the bactericidal properties of the blood flowing through the site of irradiation, and in this way the blood in the general circulation develops a greater bactericidal activity.

CHRONIC INFLUENZAL FIBROSIS OF THE LUNGS.*

BY W. H. WYNN, M.D., F.R.C.P. LOND., M.SC. BIRM.,
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BIRMINGHAM; PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

AFTER separating out from chronic diseases of t lungs those caused by tuberculosis, syphilis, and t inhalation of dust, there remains a considerable numb of cases in which the lungs show signs of permane damage in the form of fibrosis, more or less bronch dilatation, and possibly thickened pleura. These ca are diagnosed under various names: unresolv pneumonia, chronic pneumonia, interstitial pneumon fibroid lung, fibroid phthisis, &c. They have occurr much more frequently since the great epidemic influenza in 1918–19, and in my experience now fo the largest class of chronic lung disease, outnumber even tuberculosis. They are more often mistaken tuberculosis than any other condition. But althou they may occasionally be associated with a tubercul infection, they do not predispose to that disease, a usually run a separate and parallel course. T damage is a sequel to an acute infection which m have become extinct, but more often persists, c tinuing to irritate and cause more damage, so that have to deal with a progressive disease. Althou doubtless, many infections may lead to fibrosis, my opinion the commonest cause is infection with influenza bacillus. Chronic influenzal fibrosis not o forms the largest group, but in its typical form prese distinct features by which it can be recogni clinically, and separated from fibroses of other orig

Cases of fibrosis of the lung fall naturally into groups: (1) those arising in childhood, and (2) th arising in adult life. The former group has long b recognised. They begin usually within the first years of life, and follow an attack of bronc pneumonia, either simple or associated with whoop cough or measles, or they may follow repeated att of bronchitis.

A typical case is that of a child of 8 or 9, wh brought with the complaint that he has had a co and has not been really well since he had bron pneumonia at the age of 4. The cough tends to o in paroxysms, and is at its worst in the morning waking, when it may persist for half an hour or m and leave the child exhausted. Sometimes vomi occurs in the paroxysms. Slight exertion, excitem or talking may also bring on the cough. It is alv worse in the winter, but may persist through summer. Sputum is scanty, viscid, and hard to b up, unless there is bronchial dilatation, when more abundant. Occasionally there may be bloo it. On examination there is diminished expansion some flattening of the lower part of the chest on side. There is some alteration of resonance, var with the amount of fibrosis and thickened ple Breath sounds are diminished, but may be bron or cavernous when there is bronchiectasis. Nume râles are heard over the affected area, and perhaps a at the base of the opposite lung. Tonsils and ader have probably already been removed, but the may still be a mouth-breather, and muco-pus ca seen in the nasopharynx. The general health is impaired than might be expected from the cond of the lung, but the child is pale and a little unde average height and weight. At more or less freq intervals there are exacerbations with a ris temperature, and an increase in symptoms and s Râles become more numerous, and may lead diagnosis of broncho-pneumonia, but the conditi one of increased catarrh in a fibroid lung. S cases may become stationary or even lose their s and the children grow up well, and able to live no lives, but very often signs persist; the disease sl

* A post-graduate lecture given at the General Hos Birmingham.

progresses, the children are frequently unwell and have long periods of absence from school; well-marked signs of bronchiectasis develop with more abundant sputum, dyspnœa, and clubbing of the fingers. Life then becomes precarious, although they may struggle on to early adult life or even middle age.

It is, however, to the second group, those arising in adult life, that I wish especially to call attention, as the importance and frequency of the condition are not yet fully recognised. It is in this group that the etiological significance of the influenza bacillus becomes prominent. For this paper I have looked through the notes of 100 adult patients, mostly seen during the last three years, in all of whom signs of fibrosis of the lung were associated with the presence of influenza bacilli in the sputum. Whether or no Pfeiffer's bacillus is the cause of epidemic influenza, it is certainly the commonest associate of this disease, responsible for some of its peculiar features, and is a very persistent inhabitant of the damaged lungs so often seen as sequelæ. The bacteriology of the broncho-pneumonias of childhood and their sequelæ requires more investigation, but the influenza bacillus is frequently found in both the primary and secondary broncho-pneumonias, and fibrosis appears to be more frequent when this bacillus is present.

Ætiology.

Chronic influenzal fibrosis occurs equally in the sexes. Fifty-three cases were males and 47 females. It is found at all ages, but is most commonly seen between the ages of 30 and 55, 69 cases being within these limits. This refers to the ages when first seen by me and not to the age of onset, which was usually a few years earlier. These ages correspond with the fact that influenza in epidemic form has been particularly a disease of early adult life, and that we are now seeing the scars left by the epidemic of 1918 and subsequent years. Fibrosis seems less common during the 'teens, so that there is a gap between the fibroses of childhood and those of adults. This is partly bridged by cases produced in childhood and carried over into adult life.

The important point in the history of these cases is that, with few exceptions, patients could definitely trace back their trouble to some acute respiratory infection, and in at least 80 per cent. this event occurred in adult life. "I was quite well until I had influenzal pneumonia in 1918, and since then I have never been free from a cough." "I had influenza five years ago and have had several attacks since; these attacks are getting more severe, and I am away from business several weeks in the year." "I have had coughs and colds all my life, but they have been much worse since the influenza epidemic." "I had whooping-cough three years ago, when my child had it, and I have not been well since." These are typical histories.

In 25 cases there was a history of influenzal broncho-pneumonia; in 12 during the epidemic of 1918–19, and in the others during subsequent minor epidemics. In 17 others there was a history of severe influenza during epidemics. Twenty-one dated the onset back to a severe cold with bronchitis, not definitely called "influenzal," though associated facts suggest that some, if not all, of these were influenzal infections. Seven had suffered from bronchitis for years with repeated acute attacks. Five traced their illness back to whooping-cough in childhood, and one to whooping-cough three years before. One had pneumonia after measles, and one after scarlet fever in childhood. Six had had coughs and colds as long as they could remember, but had been much worse the last few years. One was gassed in the war, and in seven the first onset was with asthma. In four only was the onset insidious, and no definite time could be stated when the cough began.

Bacteriology.

In all these cases the influenza bacillus was grown from the sputum and in the majority it was also found in cultures from the nasopharynx. The growth was abundant but never pure. The commonest associated organisms were streptococci and *M. catarrhalis* in 94 and 70 per cent. respectively. The pneumococcus was only found in 24, which seems surprising when we remember the frequency with which it is found in acute diseases. Fibrosis, however, is rare after lobar pneumonia, which is a pure pneumococcal infection, and true lobar pneumonia has been infrequent in recent years as compared with the pneumonias caused by mixed infections. It would seem that the pneumococcus is not a very persistent organism in the lower respiratory tract. Friedländer's bacillus, *Micrococcus paratetragenus*, diphtheroids, and staphylococci were also found occasionally.

The influenza bacillus is not only a very persistent organism in the lung, but is very often found also in chronic infections of the nasal sinuses, so that in many cases there is a widespread infection of the whole respiratory tract. We do not know much about the frequency of infection with the influenza bacillus in inter-epidemic periods prior to 1918, but Pfeiffer in 1893 recognised that the influenza bacillus could exist for long periods in the sputum and that there were chronic forms of the disease. Ortner in 1902 found the bacillus in cases of chronic bronchitis, and since Lord's papers in 1902 and 1905 occasional articles on chronic influenza have appeared in American medical literature.

Symptoms and Signs.

On examination all the cases showed some signs of fibrosis of the lungs, varying from slight signs at one or both bases to a widespread bronchiolectasis or a massive fibrosis of one lobe or the whole of a lung. The physical signs naturally vary from case to case, but in an individual case they are remarkably persistent and, except during exacerbations, show little change.

The cases can roughly be classified into five groups for the convenience of description.

1. *Chronic Bronchiolectasis.*—This is the most characteristic and severe form. It is illustrated by the following cases:—

CASE 1.—A matron-in-chief of one of the army areas in France had influenzal broncho-pneumonia in January, 1917, and was seen by me in the following May. She then complained of great weakness and of becoming exhausted on slight effort. She had only a slight cough. She had lost weight from 8 st. 4 lb. to 6 st. 4 lb. during her illness, but had since gained and was 8 st. 7 lb. She looked thin and pale. The chest showed poor expansion and impaired resonance, especially over the upper lobes, but the striking sign was the presence of medium-sized moist râles over the whole of both lungs. The diagnosis of tuberculosis had been made, but tubercle bacilli had not been found in the sputum, and with tuberculosis of the extent shown by the physical signs a patient could not walk about and be free from fever. The signs were those of a general bronchiolectasis and the sputum contained large numbers of influenza bacilli. She had prolonged treatment with an autogenous vaccine, rest and change of air, and in February, 1918, her general condition had improved sufficiently to return to duty in France, although physical signs were little altered. She developed sciatica a year later and was finally invalided in April, 1919. The physical signs continued with little change until she died in November, 1924, after a long period of increasing dyspnœa.

CASE 2.—A woman, aged 39, consulted me for rheumatoid arthritis, which began after an attack of influenza six months before. The joints showed typical rheumatoid changes. There was no complaint of a cough, but she was slightly cyanosed and dyspnœic. All over both upper lobes were the same medium-sized moist râles. The sputum, which was scanty, contained numerous influenza bacilli with streptococci. She was under observation for three and a half years, but, whilst the joints improved, the signs in the lungs persisted unchanged, breathlessness gradually increased, and she died from heart failure during an acute exacerbation.

Such cases, in my experience, were rarely seen prior to 1918, and every case of general bronchiolectasis I have seen since that date has been associated with the influenza bacillus. The physical signs are very characteristic and even startling: abundant medium-sized moist râles heard over the whole or the greater part of both lungs of a patient who, whilst distinctly unwell, is yet able to walk about. I have several times made the diagnosis of influenzal bronchiolectasis from

the physical signs alone, and this has been confirmed by the sputum examination.

2. *Localised Bronchitis.*—This is really a slighter form of the first variety. Over some area of the lung, more often in a lower lobe than an upper, are constantly heard râles, fine or medium, crackling or bubbling, with some rhonchi. At times rhonchi may be heard all over the lungs from a general bronchitis, but when this subsides râles still persist over a definite area. X ray examination will show increased lung striæ spreading from the root towards the damaged area. The condition is one of fibrosis with some dilatation of the smaller tubes forming a chronic focus of infection which in acute exacerbations spreads to the rest of the lungs. Frequently there are other chronic foci of infection in the nose and throat.

3. These cases may in addition have *asthma.* In seven of my cases the first complaint was of asthma, and in eight others it became a prominent symptom later. The physical signs are like those of the previous group—localised râles in some portion of the lungs with sibilant rhonchi during asthmatic attacks. In between attacks the râles persist. Nasopharyngeal infection is almost invariably present.

4. *Massive fibrosis* is a less usual condition.

CASE 3.—A man, aged 45, was seen last February. He had influenza in 1923 and since then cough and sputum had been gradually increasing in amount and he had become very dyspnœic. He was regarded as asthmatic, but the dyspnœa was both inspiratory and expiratory. Breathing was noisy and almost stridulous. It was apparent that there was some gross obstruction to his bronchi, although at times there was probably some added spasm. At first the noisy breathing occurred only during sleep, but latterly it was present day and night, but varied in intensity from time to time. The sputum, which was not abundant, contained large numbers of influenza bacilli. There was lessened expansion of the left side of the chest; breath sounds were harsh with prolonged expiration. Râles were heard all over the left lung, especially at the base, and there were râles also at the base of the right lung. X rays showed a dense shadow at the root of the left lung with much striation throughout that lung and to a less extent in the right lung. He has improved under treatment and though still dyspnœic has lost the noisy breathing.

CASE 4.—A man of 50, tall, well built, and of not unhealthy appearance, has had a morning cough and sputum since an acute illness in 1917. From the history it is probable that this was influenza. There have been occasional febrile attacks with increase of cough and for the last four months he has complained of feeling unwell. The left side of the chest shows deficient expansion, the apex beat is in the axillary line, and the right lung has crossed beyond the sternum. The greater part of the left side is dull on percussion, with some resonance at the apex due to the trachea being drawn to the left. Breath sounds are bronchial at the apex from the same cause, but diminished or absent elsewhere. There are a few râles at the base. The sputum is usually viscid and scanty, but on several occasions there has been a profuse hæmoptysis. *B. influenzæ, M. catarrhalis,* and streptococci were isolated from his sputum. X rays showed a dense shadow over the whole of the left side of the chest with the mediastinum drawn to the left. Here thickened pleura appears to be associated with considerable fibrosis.

5. *Bronchiectasis,* of the text-book description, with abundant sputum, possibly foul-smelling, clubbing of the fingers, cyanosis, &c., is not often seen in these cases. It was present in four, but in each was of long duration and the history suggested that the fibrosis began in childhood. The influenza bacillus may have been a secondary invader.

Fibrosis in children is most common in the lower lobes and on the left side. In these adult cases there is not quite the same predilection for the bases. In 63 the changes were limited to the lower lobes, in 24 the upper lobes, and in 13 both upper and lower lobes. In 20 the right lung only was affected and in 19 the left lung only; in the remainder both lungs were affected to a varying extent; in 36 over limited areas at both bases, in 11 in both upper lobes, in 8 the whole of both lower lobes, in 1 small areas at both apices, and in 5 the condition was general in both lungs.

General Symptoms.

All the patients complained of fatigue and general weariness; they were often regarded as neurasthenic. Fits of depression were not infrequent and one patient committed suicide. Nearly all showed som signs of the effort syndrome, shortness of breath c slight exertion, palpitation, pain around the heart, an a quick pulse. The temperature was normal excep during acute exacerbations. In women an exaggera tion of the premenstrual wave was commonly seer Patients were often under weight, but not striking l so, and in a few cases, especially in women about th climacteric, there was obesity. As in other chroni infections thyroid disturbances were sometimes seen In the younger patients this was in the direction o hyperthyroidism and in one there was well-marke Graves's disease which began after an attack o influenza. Slight hypothyroidism was sometimes see in the older women. Paræsthesiæ, tingling an numbness in the hands and feet, cold and blu extremities, fibrositic pains, neuritis, and occasionall arthritis were all sometimes present. There appeare to be an abnormal reaction of the capillaries to col and a consequent proneness to rheumatic disorders.

I have already called attention to the frequency o associated infection of the nose and throat. Chron sinus infection, enlarged tonsils, polypi, and nas pharyngeal catarrh are recorded over and over agai My impression is that patients with a pre-existin unhealthy condition of the nose and throat are mo prone to suffer from chronic infection of the lun after broncho-pneumonia than normal patients, an this is especially so in children, but frequently th onset of the nasal infection is coincident with that the lungs.

An appreciable hæmorrhage occurred in seven, an in three this was at times alarming. Small strea and clots in the sputum were frequently seen. Th hæmoptysis naturally gave rise to fears of tuberculos It is not sufficiently realised that a large hæmorrha may occur in non-tuberculous fibrosis. When hæmo rhage occurs with absent or scanty physical sign tuberculosis is the most likely cause, but wh extensive physical signs are present, especially at th base, fibrosis with bronchial dilatation must considered as a possibility.

Pathology.

So far I have not obtained a post-mortem examin tion in a case which I have studied during life, an the exact condition of the lungs must be inferred fro the physical signs, the known lesions of influenza a our general knowledge of fibrosis following acu infections. In influenza the bronchioles are especia attacked, the alveoli being secondarily affected. Th bronchioles become blocked with secretion a desquamated cells. The mucous membrane is destroy and the bronchiolar wall infiltrated with inflammato cells and exudate, so that it becomes greatly thicken and extends into the surrounding lung. The next st is organisation of the inflammatory tissue and fibros Dilatation of the bronchioles may occur during th acute stage, or more gradually from the traction of ne formed peribronchial fibrous tissue. The final conditi is one of peribronchial fibrosis with dilatation varying extent. If the changes are slight and th infection becomes extinct the process may stop. I in the cases here under consideration the infecti persists, fibrosis increases, and we have a progress disease.

X ray examinations are very helpful. Whilst th physical signs are mainly those of catarrh, the X ra show the extent of permanent structural chan Although sometimes they show little, in spite o extensive physical signs, more often they reveal m extensive lesions than the physical signs suggest The most common condition is an increase of the re shadows and of the striæ extending outwards fr the roots. These extend particularly towards th base, but may go to an upper lobe or throughout th lung. The cardiophrenic angle may be obliterat and the outline of the diaphragm be irregular a angular, presumably from the traction of adhesio The normal reticular structure of the lung may be exaggerated or may have a honeycomb appearan Occasionally there is general dimming from masse fibrosis or thickened pleura. Lipiodol injections ha

furnished a means of determining more accurately the presence of bronchial dilatations.

Diagnosis.

The most important error in diagnosis is to mistake these cases for tuberculosis. Various statistics in recent years have shown that from 30 to 70 per cent. of cases diagnosed as tuberculous and sent to tuberculosis experts have proved to be non-tuberculous. Among these cases chronic influenzal fibrosis occupies a prominent place. The following points help in recognising the condition.

1. The history is of great importance. In tuberculosis the onset is usually insidious. In influenzal fibrosis the symptoms can be traced back to some acute illness. The history that the patient has not been well since an attack of broncho-pneumonia, influenza, or whooping-cough should at once lead to the suspicion that the disease is of a non-tuberculous nature. Influenza may, of course, stir up a latent tuberculosis, but this occurs less often than has been supposed. Confusion may also arise from mild attacks of fever due to tuberculous auto-inoculations being described as influenza.

2. Non-tuberculous cases usually show fair general health, in spite of signs in the lungs which, if they were due to tuberculosis, would be associated with considerable ill-health.

3. Tuberculosis has its sites of election, and in its progress follows a definite line of march. Influenzal fibrosis does not show the same tendency to spread to fresh areas of lung. The disease remains localised. Progress is marked by increased fibrosis or bronchial dilatation in the same area rather than a spread to other parts.

4. It is usually taught that tuberculous cavities are apical and bronchiectatic cavities basal, but this rule has many exceptions, and influenzal fibrosis quite commonly occurs in the upper lobes.

5. Repeated examinations of the sputum for tubercle bacilli must be made. If always negative the condition must be regarded as non-tuberculous, for we are not now dealing with cases simulating early tuberculosis, but with those showing well-marked signs in which tubercle bacilli would be found if present. The two diseases may, of course, be associated. In four of my cases both tuberculosis and influenza were present, but in each the tuberculosis was the primary condition, and influenza an added infection. I do not include here cases definitely tuberculous in which influenza bacilli are found as a secondary infection, but cases of fibrosis in which the diagnosis was in doubt. Systematic examination of the sputum should be made for influenza bacilli as well as for tubercle bacilli in all cases of chronic lung infection.

6. The characteristic physical sign in influenzal fibrosis is the medium-sized bubbling râle. In tuberculosis clicking and consonating râles are heard, but the distinction must not be pressed too far.

7. The X ray picture differs from that of tuberculosis. It may resemble that of so-called hilum phthisis, and, indeed, I consider that many cases described as hilum phthisis are in reality cases of non-tuberculous fibrosis. When massive fibrosis is present with considerable dullness, dense X ray shadows and hæmoptysis, the possibility of a malignant growth must be considered. Pain is an early symptom of malignant growth, and is absent with fibrosis. Dyspnœa is more marked and the general health more disturbed, but in some cases time alone will settle the diagnosis. The presence of influenza bacilli in the sputum is not conclusive, as there is some evidence that influenza predisposes to malignant growths of the lung. Bronchiectasis, bronchitis, and asthma may be component parts of the picture of influenzal fibrosis, and in all these cases the sputum must be examined for influenza bacilli.

Treatment.

Fibrous tissue once formed cannot be removed. The lung is permanently damaged. Treatment is therefore limited to attempts to improve the general health and to control the infection, with the object of preventing acute exacerbations, lessening cough and sputum, and impeding the progress of the disease. When patients can afford it, removal to a more equable, sunny climate will increase their comfort and prolong their lives. The nose and throat in many cases require efficient treatment to prevent foci of infection there from reinfecting the lungs. It is futile to expect improvement in the lungs when the upper respiratory tract is grossly infected. Treatment with autogenous vaccines is of great value, and I have seen considerable improvement after their use. In slight cases physical signs may disappear entirely. In more advanced cases the general health improves, cough and sputum become less, and exacerbations are controlled. As in other chronic infections the patient is "sensitised" and the initial dose of vaccine must be small, not exceeding one million. The dose is gradually increased, reactions being carefully avoided, and the treatment may have to be continued for 6 to 12 months. In spite of treatment the infection persists in many cases; the patients are "carriers," as is only to be expected in view of the permanent structural changes. In such cases relapses are likely to occur, and it is therefore wise to give a few prophylactic injections of vaccine each autumn and spring.

So far little attention has been paid to the prevention of fibrosis following acute infections. We do not know how long a broncho-pneumonia can remain unresolved and yet the lungs eventually return to normal, or at what stage the diagnosis of unresolved pneumonia must be changed for that of fibrosis. My own impression, after numerous X ray examinations, is that most cases of unresolved pneumonia are left with some permanent structural change, although there may be no symptoms and no catarrhal signs for long periods. It is necessary to make sure in every case of broncho-pneumonia that the condition has entirely cleared up before the patient passes from our care. If, after the temperature has fallen, the physical signs are slow in clearing up, efficient vaccine treatment, combined with such general measures as graduated rest, open air, the avoidance of fatigue, &c., would prevent many lungs from being permanently injured. We should be as anxious about the lung after acute diseases as we are about the heart in acute rheumatism.

Clinical and Laboratory Notes.

A CASE OF SPONTANEOUS PNEUMOTHORAX TREATED BY GAS REPLACEMENT.

BY JAMES D. MACFIE, M.B., CH.B. GLASG.,
SENIOR RESIDENT MEDICAL OFFICER, WINSLEY SANATORIUM, NEAR BATH;
AND
ROBERT L. OSMASTON, M.R.C.S. ENG.,
ASSISTANT RESIDENT MEDICAL OFFICER.

THE following case is of interest in showing the excellent results that may follow gas replacement in spontaneous pneumothorax:—

The patient, a grocer's assistant, male, aged 19, was admitted to the Winsley Sanatorium on June 17th, 1927. He had influenza last February and cough persisted. On June 4th he had a hæmoptysis of about half a pint. His mother has consumption with laryngeal involvement but has reacted very well to treatment at home, thus showing a good family resistance, which we thought to be in the patient's favour.

Condition on Admission.—General health poor; anæmic and rather hoarse. The physical signs in his chest showed involvement of both lobes of the left lung with moist sounds more numerous in the lower lobe. Pulse-rate, 88 morning, 96 evening; respirations, 20 morning, 20 evening. Bowels opened regularly, sputum ʒii. in 24 hours; T.B. +.

Progress.—For the first 18 days he ran a somewhat irregular temperature, never rising above 100° F. (oral), but this then subsided and he was allowed out of bed and put on graduated walks—namely, half an hour in the morning and afternoon. The laryngeal condition was treated by allowing "whispers only."

Onset of Spontaneous Pneumothorax.—On July 24th, at 4.30 P.M., during an attack of coughing, the patient was seized with a sudden acute pain in the left chest together with dyspnœa and faintness; he had to be assisted to bed. His temperature rose to 100° F. that evening and varied from 99° F. to 100° F. until the evening of July 28th, when for three days it varied from 102° F. to 103·4° F. The pulse at the same time was 120–146, respirations 40–44. He suffered from severe fits of coughing, causing much pain in the left chest, and from dyspnœa and a feeling of tightness which varied considerably from time to time.

The physical signs in the chest were those of a spontaneous pneumothorax with fluid. The heart was pushed well over, the apex being at the right margin of the sternum. Breath sounds were weak or absent on the left side. The percussion note was tympanitic above but dull at the base. Hippocratic succussion and the bruit d'Airain were readily obtained and he suffered from severe dyspnœa.

Early Treatment.—The patient was kept at absolute rest in bed with ordinary treatment for fever. Morphia (gr. ¼) was given and the left chest bound with adhesive strapping.

Gas Replacement.—On July 29th, owing to an exacerbation of the dyspnœa and other symptoms, a gas replacement (air) was done at 11·45 A.M. On introducing a pneumothorax needle into the second intercostal space in front, the pressures stood at ±0, +10. A second needle was now introduced into the ninth space behind and 480 c.cm. of clear straw-coloured fluid were withdrawn. At the same time 300 c.cm. of air were introduced through the first needle. At the conclusion of the operation the pressures stood at ±0, +10.

Further Progress.—From that time the patient's condition steadily improved. On August 7th a refill was performed and 400 c.cm. of air were introduced, this time into the fifth space in the mid-axillary line. The pressures before and after were respectively −6, −1, and +3, +9.

On August 11th his morning temperature, pulse, and respirations were respectively 97° F., 88, 24, and in the evening 98·4° F., 100, 26, showing a very marked improvement in his condition. On the 17th, the temperature being still quite normal, he was again refilled, the readings being +3, +4 : 350 c.cm. +7, +12.

Another refill on the 22nd : +3, +7 : 200 c.cm. +7, +12.
" " the 29th : +2, +6 : 200 c.cm. +6, +10.
" " Sept. 5th : +2, +6 : 350 c.cm. +9, +14.

Now he has ℥ii. sputum, bowels regular. Temperature, 97° F. morning, 98·2° F. evening; respirations, 20 morning, 22 evening; pulse, 86 morning, 104 evening.

The rationale of the treatment is to remove the fluid, which may become purulent with disastrous results, and at the same time to introduce sufficient air to prevent the intrapleural pressure falling to such a degree that the valvular opening in the lung reopens. With a negative or atmospheric pressure this might easily happen during a fit of coughing or any undue exertion. Reopening the communication between lung alveoli and pleural cavity of course greatly increases the risk of infection of the latter.

An interesting point in the technique is the decision as to what pressure to leave in the pleural cavity after the operation. In this case it was decided to leave the pressures the same as they were before removal of the fluid. This pressure presumably approximates to the pressure in the lung during a fit of coughing. Any pressure higher than this would cause unnecessary discomfort, and undue strain would be thrown on the other lung and on the heart. Any pressure lower than this would, as stated above, leave the patient open to the risk of re-establishment of the communication between lung and pleural cavity. The remarkable feature was the improvement in breathing, which was unexpected, considering that the pressures were left unaltered. The load on the diaphragm would, however, be reduced by the weight of 480 c.cm. of fluid, which would, of course, have been acting in addition to the pressure in the gas cavity. We are prepared, however, to believe that the operation had a great moral effect on the patient, as pure shock plays such a predominating rôle in the prognosis with spontaneous pneumothorax.

For the future it is proposed to treat the case as an ordinary artificial pneumothorax. One of the advantages of removing part of the fluid is that this hastens the absorption of the remaining fluid, as experience has shown. Once the fluid is all absorbed and the opening in the lung securely healed, the prognosis must become that of an ordinary artificial pneumothorax. Unfortunately, secure healing of the hole in the lung is difficult to attain.

The hazards of the operation are, in the first place, those inherent in ordinary artificial pneumothorax therapy, with an especial risk of infecting the fluid in the cavity. In the second place, there is the danger of letting the pressure fall too low and hence increasing the risk of infecting the cavity from within.

This patient was not X rayed on admission but the X ray now shows a good collapse and fluid up to the fourth rib. The throat, as so often occurs in pneumothorax cases, is gradually improving and his general all-round condition is quite satisfactory. Spontaneous pneumothorax is, no doubt, much commoner than we imagine (cf. one of the hypotheses of the pleural rings so frequently met with in ordinary X ray photographs), but is often probably of little but academic interest.

A CASE OF FOREIGN BODY INADVERTENTLY SWALLOWED.

By S. F. ALLISON, M.B., CH.B. EDIN., D.P.H. CAMB.,
ASSISTANT MEDICAL OFFICER, HAM GREEN HOSPITAL AND SANATORIUM, PILL, NEAR BRISTOL.

THE following case is worthy of note because a piece of razor blade was evacuated after traversing the whole alimentary canal with practically no untoward consequences.

On Sept. 1st, 1927, the patient, a man of 30, was admitted to Ham Green Hospital suffering from scarlet fever. He was well developed and, though certainly not mentally defective, was rather obtuse and disobedient. At 3 P.M. on Sept. 9th, while eating toffee, the patient swallowed a triangular piece of "safety-razor" blade, with a long side made by the cutting edge of the blade, and an acute angle making a sharp needle-like point.

The only immediate result was the expectoration of 2 oz. of blood, presumably from the mouth. The same evening a meal of cotton-wool and jam was administered, and the following morning (6 o'clock, Sept. 10th) a meal of thick oatmeal porridge. At 11 o'clock on the morning of the 10th an X ray photograph was taken. This photograph showed the blade almost halfway up the ascending colon, embedded centrally in its contents. By a curious coincidence another adventitious shadow cast in the left costal region led to further questioning, which elicited the information that some time previously a needle had penetrated his chest wall and had not been recovered. At 2 P.M. on Sept. 11th 1½ oz. of castor oil were given and the patient was kept under close observation. The sequence of events then was:—Sept. 11th: Bowels open 5 P.M., one stool and small quantity of wool; bowels open 8.30 P.M., normal stool. 12th: Bowels open 4 A.M., major quantity of wool and stool; bowels open 6.30 A.M., passed blade in stool, darkish in colour, but otherwise unaltered.

It is interesting that the blade was not passed with the wool. The patient now (Sept. 20th) appears to be making favourable progress, and suitable measures have been adopted to prevent a repetition of the experiment.

I am indebted to Dr. B. A. Peters for his permission to record the incident.

A NOTE ON SCARLET FEVER OF TOXIC TYPE.

By CYRIL BANKS, M.B., B.S. LOND., D.P.H. SHEFF
MEDICAL OFFICER OF HEALTH, COUNTY BOROUGH OF HALIFAX.

THE text-books contain references to cases of scarlet fever of a fulminating character which rapidly produces death, sometimes before the rash has appeared. The symptoms are vomiting and diarrhœa suggestive of the effects of an irritant poisoning. The reader is inclined to ask how such cases can be labelled as scarlet fever in the absence of the characteristic symptoms and signs of that disease; presumably the diagnosis has been made because other cases presenting the ordinary signs of scarlet fever have occurred in such a way as to suggest relationship

between the two illnesses. It is therefore of some importance to place on record occurrences which support the view that scarlet fever does occasionally produce the symptoms referred to, and cause death before the appearance of a rash. Here is such a case :—

On the evening of Sept. 12th, 1927, Dr. E. W. S. Hughes, of Halifax, was called to see a girl, 5 years of age, who had been taken suddenly ill during the day with much vomiting and diarrhœa. She was collapsed and semi-conscious. Next morning she died. Naturally Dr. Hughes suspected poisoning by food, but an inquiry into the dietary revealed nothing suspicious, except that shortly before becoming ill she had eaten an apple ; other apples from the same batch were therefore examined by the borough analyst but no arsenic was found. The coroner ordered a post-mortem examination, and the stomach and intestines were submitted to Dr. F. W. Eurich, of Bradford, for bacteriological examination, but he reported that there were no organisms present which would account for the child's symptoms.

The day after the girl died her brother was taken ill, and three days later he was admitted to the fever hospital suffering from scarlet fever, mild in type but definite in nature, and of normal course. Hearing of the earlier occurrence I was able to suggest to Dr. Hughes that the first case was one of toxic scarlet fever of fulminating character as described in the text-books but rarely seen ; this explanation of the death was given to the coroner and accepted.

It is impossible to prove any real relationship between the two illnesses, but the occurrence is regarded as worth recording.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF EPIDEMIOLOGY.

AT a meeting of this Section held on Oct. 28th Dr. S. MONCKTON COPEMAN, F.R.S., the President, in the chair, Dr. E. W. GOODALL read a paper on the

Epidemic Constitution.

In recent years, he said, there had been a revival of an old doctrine which had seemed to have died out of this country about the middle of the last century. It had never been seriously discussed at any of the Epidemiological Society's meetings, though reference was made to it by Inspector-General Robert Lawson, who was President of that body, in 1863 and again in 1874. Apparently Sir Thomas Watson adhered to it in 1871. Dr. F. T. Roberts, however, referred to it only to characterise it as a mere hypothesis. In 1884 Dr. J. S. Bristow brought it into his consideration of predisposing causes of diseases, and definitely rejected Sydenham's idea that the constitution was able to impress its characters on diseases concurrent with the principal epidemic disease. But he added that admittedly there was something remarkable about the way in which diseases—contagious, zymotic, simply inflammatory—became prevalent in a high degree over wide areas. Dr. Goodall said this was the last reference to the epidemic constitution which he could find in the literature of this country, but in France the idea seemed to have survived until the year 1896. Perhaps the chief cause for the decay of the doctrine in Britain was the growth of belief in the germ theory of infectious diseases, a subsidiary reason being that Government and official investigators did not favour it. Now, however, in the annual report of the chief medical officer of the Ministry of Health for 1925 there seemed to have been acceptance, in regard to influenza, of the "epidemic constitution" as a fact. In view of this it was of interest to inquire what was meant by the epidemic constitution. Hippocrates was said to have ascribed epidemics to something divine, as due to some unknown and inexplicable cause, but there seemed no good reason for attributing such a view to him. Among the natural causes of many diseases weather conditions were of the first importance. Hence arose the doctrine of the "constitution"—i.e., the doctrine of the season. In 1546 Fracastor provided another instrument for research into the causes of epidemics, when he clearly explained the modes by which infection could be spread. He applied the doctrine of contagion, the essence of which he believed to be a living organism, to explain certain diseases which were epidemic.

Sydenham divided the prevalent epidemic diseases into two groups: "the stationary," and the "intercurrent" or "sporadic" fevers. The former was the more important group. His intercurrent fevers were dependent upon more or less obvious causes, such as the temperature of the air, the rainfall, and the prevalence of certain winds. The stationary fevers depended upon "the epidemic constitution"—in other words, the constitution of the atmosphere. The duration of the stationary fever was said to be variable. Sydenham in his time recognised seven "constitutions"—those of the intermittent fevers, plague, small-pox, dysentery, comatose fever, depuratory fever, and continued fever. It seemed to the writer, however, impossible to find out exactly what Sydenham meant by the term "epidemic constitution"; it was a vague something over and above the more or less obvious causes of disease, whose presence was necessary before there could be an epidemic. For example, sporadic cases of plague might occur from time to time, but unless a pestilential constitution of the air arose there would be no epidemic of plague.

Dr. Goodall said he had had 40 years' experience of epidemic diseases—i.e., diseases in which the phenomenon should especially be manifest—and practically all of it had been in London, so that his experience had not been subject to the disturbing influences of change of locality. Among the cases admitted to the North-West London Hospital at Hampstead during the winter of 1924 and the following spring, influenza was the stationary fever of the period ; whooping-cough, scarlet fever, diphtheria, mumps, rubella, and chicken-pox were the intercurrents amongst the infectious diseases. He found no evidence whatever that these last-mentioned diseases bore any trace of influenza, and that had also been the experience of former years. He was not a believer in the doctrine of the epidemic constitution as set forth by Sydenham and the revivalists. He was prepared to substitute alternative teaching.

The first question which should be asked by those who took up the study of epidemiology was, Why were there epidemics at all ? He would answer that the epidemics were the expression of the warfare ever going on between human beings and animals on the one hand and micro-organisms on the other. If there were no micro-organisms there would be no epidemics of those diseases which had a microbic cause. The epidemiologist had to consider not only the human being and his surroundings, but also the micro-organisms and their surroundings. The genesis of an epidemic did not depend on one single cause, scarcely upon one outstanding cause aided by minor causes. Even the presence of micro-organisms was not necessarily the principal factor in the combination of events which brought about an epidemic. An epidemic was the result of the interplay of several factors, the kind and number of which varied for each disease. Serum sickness, for example, did not always attack the same proportion of those who were injected with the serum ; at one time nearly all the injected suffered from the sickness, while at another time most of them escaped. And the symptoms of this sickness varied from time to time too, for the rash was not the same in all collections of cases. These variations had now been found to be due partly to the ages of the patients who were treated with the serum, partly to the source of the serum (the animal from which it had been obtained), partly to the dosage, partly to whether or not it had been subjected to a special chemical treatment.

Dr. Peters had defined "epidemic potential" as being the head of power for epidemic spread present at any particular stage of the epidemic, as gauged by the intensity of the infectivity over the lowness of the susceptibility of the population. There was need for a term which would express the pre-epidemic phase. "Epidemic constitution" as a term in epidemiology should, he considered, be discontinued, as its use tended to conjure up in the mind a vague and mysterious phantom. He pleaded for the adoption of Dr. Peters's term "epidemic potential," giving to that the extended meaning suggested by Prof. Topley in his Milroy lectures of last year—namely, "the balance of interacting forces which tends towards the occurrence of an outbreak of disease."

Discussion.

Sir WILLIAM HAMER said it ought to be realised that there were three Sydenhams, representing different phases of his conception of various medical problems. It was the second Sydenham who took the world of medicine by storm. With regard to the attitude of the Ministry of Health, he asked Dr. Goodall to restudy the "setting" of that Ministry as indicated in its report for 1920. Sydenham's voice still spoke to the present generation, though his viewpoint was the antithesis of that held to-day. The task of his followers was to make those two opposites into a higher unity.

Prof. M. GREENWOOD said he felt much interest in Dr. Goodall's statement that the Ministry of Health had officially adopted the "epidemic constitution" in its C.M.O.'s report for 1925. But the only reference he could find in it to justify this allegation was the following: "As far as the 'epidemic constitution' of influenza is concerned, which has played so large a part in our records of mortality since 1889, there is little to be said"—surely a very chary adoption of the doctrine. The phrase "epidemic constitution" was, Prof. Greenwood considered, a very unfortunate one, and it would be a great advantage if it could be excluded from epidemiology. In regard to Sydenham's theoretical teaching, the speaker supported what Dr. Goodall said in the paper, as he had never been able to understand what Sydenham meant, and it was significant that though that authority made theoretical distinctions, he did not carry them into his treatment, for he used the same treatment for every constitution. In the views they had expressed, Hamer and his school were about 150 years ahead of their time; they were attempting to synthesise without the necessary information. What was needed was a study of epidemics on a smaller scale, of a succession of epidemiological phenomena in populations of animals which were shorter-lived than man; then knowledge so derived could perhaps be applied to successions of human epidemics.

Prof. W. W. C. TOPLEY expressed his general agreement with Dr. Goodall's views, and as to the great value of such descriptions as Sir William Hamer had given of the succession of diseases. At present the data available for a study of such problems did not enable one to go very far.

Dr. J. D. ROLLESTON remarked that the Plague of Athens, in his view, more nearly resembled typhus than any other disease. Thucydides said that the year of the plague was singularly free from all other diseases, and added that whatsoever diseases there were became converted into it. In connexion with such a recent epidemic as that of diphtheria in Paris in 1926–27, the French spoke of a constitutional tendency accounting for the intensity of the disease at that time. With regard to serum disease, cases of this were less frequent since the introduction of refined serum. This disease was best studied in connexion with diphtheria, owing to the universal treatment of it by serum. The more severe the attack of diphtheria, the less likely was serum disease to occur. And some parallel to this was seen in the case of small-pox.

MEDICO-LEGAL SOCIETY.

RECENT ADVANCES IN TOXICOLOGY AND FORENSIC MEDICINE.

Sir WILLIAM WILLCOX chose this subject for his presidential address to the Medico-Legal Society on Oct. 27th. Since its foundation in 1902, he said, the Society had served a useful purpose in discussing and criticising medico-legal discoveries, and such criticism was essential, because there must on no account be any risk of inaccuracy in the results attained by scientific tests used in legal investigations. Such tests must be without flaw. He then proceeded to consider some of the ways in which toxicology assisted the law.

Arsenic.—One of the greatest recent advances in the toxicology of arsenic had been the introduction of the electrolytic Marsh test by Prof. Thorpe in 1903. The detection of minute amounts of arsenic in the urine had enabled the rate of excretion of arsenic to be accurately determined; the detection and estimation of minute quantities in the hair and nails were also often of forensic value. Thus in the Armstrong case arsenic would have never been suspected as the cause of the death of Mrs. Armstrong (who had died about a year previously) if Major Armstrong had not attempted to poison his rival solicitor, Mr. Martin, by the same means. The discovery of arsenic as the cause of Mr. Martin's illness was due to Mr. John Webster's analysis of the urine passed by Mr. Martin three days after the poison had been taken. The advantage of toxicological research was here beautifully illustrated, for the knowledge of the rate at which arsenic was excreted made it possible to deduce that Mr. Martin must have been given a fatal dose.

A Government official in a tropical country consulted Sir William Willcox on account of an illness which had given rise to much difficulty of diagnosis. On Oct. 6th 1922, he was attacked with severe abdominal pain, vomiting and diarrhœa, watery stools containing some mucus being passed. He was very ill with these symptoms for three days and had a good deal of hiccup. On Oct. 9th circumoral herpes developed. The patient remained in hospital until the 30th, when he returned to duty. He now began to suffer from slight cramps in the feet, some numbness and feeling of coldness in the hands and feet, and some weakness of the legs. Marked thickening of the skin of palms and soles occurred, and the skin peeled off here in the middle of November. In consequence of these symptoms the patient came home in November. On Dec. 19th, 1922 slight anæsthesia to a light touch was found in the hands and feet, and there was some thickening of the skin of the palms and soles. The patient consented to some of his hair being removed for purposes of analysis, and Dr. Roche Lynch submitted this to the electrolytic Marsh Berzelius test. A considerable amount of arsenic was found in the hair, 1/22nd mg. in 3 g. of the hair. The diagnosis in this case was clearly that of acute arsenical poisoning on Oct. 6th 1922, and on question it was found that the patient had had considerable trouble on that date, on account of the misbehaviour of his native cook, who was discharged from service on the following day.

This case was of great interest, said the President, since knowledge of the mode of excretion of arsenic made it possible to diagnose acute arsenical poisoning as long as ten weeks after the poison had been administered.

Arsenobenzol Compounds.—Prof. Paul Ehrlich had discovered salvarsan in 1910 and neosalvarsan in 1912. Since then innumerable arsenobenzol derivatives had been introduced, but none of them, he thought, had proved more efficacious than the original salvarsan, though many were easier to administer. Ehrlich's discovery was one of the greatest therapeutic advances of modern times. Sometimes, however, the drugs acted as severe liver poisons, and occasionally they had even produced complete suppression of hepatic function. The close relationship between toxicology and medicine was well illustrated in the fact that the occurrence of these toxic effects led to the discovery and use of tests for determining liver function.

Liver Poisons.—Knowledge of these poisons had been greatly increased during the war. The use of tetrachlorethane as one of the constituents of a cellulose solvent for the varnish used on aeroplane wings had led in 1914 to the occurrence of a large number of cases of toxic jaundice. These had been first investigated by Sir Bernard Spilsbury and the speaker, and extensive degeneration of the liver had been found in fatal cases. A harmless substitute (amyl acetate) had eventually been discovered. Trinitrotoluene was also found to cause severe and often fatal toxic jaundice in addition to other effects such as dermatitis and anæmia. Dinitrobenzene, dinitrophenol, and picric acid gave rise to similar effects. The study of the toxicology of the liver poisons met with during the war had undoubtedly thrown much valuable light on our knowledge of the pathology of hepatic diseases in general. The characteristic feature of these poisons was that they produced degeneration and destruction of the hepatic cells resulting in a replacement fibrosis in the liver when recovery from the immediate effects of the poison occurred. "I have at the present time under my care at St. Mary's Hospital," said Sir William Willcox, "a patient suffering from ascites, the direct result of a cirrhosis of the liver caused by trinitrotoluene poisoning contracted in a munition factory in 1916, at which time an attack of acute toxic jaundice occurred."

Alkaloidal Tests and Methods of Detection.—The somewhat complicated processes of extraction described by Stas and improved upon by Otto and Dragendorff were still in use. The tendency of modern work had been to simplify them, and the late Sir Thomas Stevenson had introduced a practical modification of the Stas process. The great importance of carrying out all alkaloidal extractions at temperatures not exceeding blood heat was now fully realised. It was by using the utmost care in this respect in the Crippen case that hyoscine had been successfully extracted from viscera which had been buried for six months. The application of micro-chemical methods in the testing of alkaloidal extracts enabled minute amounts to be detected. For example, in the doping of horses, it was possible to obtain the alkaloid from the saliva obtained by placing a clean sponge in the horse's mouth.

The *lead treatment* for cancer, introduced by Prof. Blair Bell, was an example of the use of a powerful poison just within the limits of its toxic action. Much light had been thrown on the toxicology of lead by its use in this manner, and it was of interest to note that the effects of intravenous injections under proper control differed considerably from those of chronic lead poisoning. In the latter the cardio-vascular system, kidneys, and nervous system generally suffered much damage, whereas this was not specially noticeable in the treatment of cancer by intravenous lead.

New Drugs.—After referring to tobacco and alcohol, Sir William Willcox turned to the consideration of new drugs. There was a tendency at the present day, he said, to select for use new and vaunted drugs of foreign manufacture. Unfortunately these were often allowed to supersede the old and well-tried remedies. The English market was flooded with all kinds of hypnotic drugs of foreign manufacture which were advertised as harmless and free from dangerous toxic effects and from the risk of addiction. From 1905 to 1925 upwards of 257 cases of fatal poisoning had occurred from the barbituric acid group of drugs (veronal, dial, medinal, luminal, allonal, veramon, &c.), and there seemed to be no sign of diminution in these tragic occurrences. Numerous cases of addiction had been reported. It could not be too strongly emphasised that new organic drugs of hypnotic action should be used with great care and caution, and statements as to their harmless nature should not be accepted at their face value. New organic compounds should also be used with care, and it should be remembered that they had in all probability a definite action on the liver and nervous system which might have toxic effects. For example, the quinoline derivatives (atophan, &c.), which were of value as uric acid eliminants, might give rise to serious hepatic disturbance. He was informed on good authority that fine chemicals and proprietary remedies were imported into this country in enormous quantities from abroad, with little restriction as regards duty, whereas similar products of British manufacture were subjected to such hampering restrictions and duties as rendered their exportation impossible.

Other Potential Poisons.—Sir William Willcox went on to speak of the toxic effects of thallium acetate, carbon monoxide, and such physiological substances as pituitary extract and insulin, whose detection, for forensic purposes, might present some difficulty. The chemistry and toxicology of bacterial toxins was, he said, a field almost entirely unexplored. Aconitine (minimum fatal dose gr. 1/30th) was one of the most deadly of the vegetable alkaloidal poisons, but compared with some of the bacterial toxins its poisonous properties sank into insignificance. Thus a therapeutic dose of tuberculin was gr. 1/10,000,000, and the toxins of other organisms are probably much more potent.

Blood Stains.—Great advances had recently been made in the examination and detection of blood stains. The chemical, microscopic, and spectroscopic tests had been improved so that by micro-chemical methods the full tests could be carried out on a minute stain. These tests, however, only made it possible to say that the stain was blood, mammalian or otherwise. Uhlenhuth, Nuttall, and others (1902–05) had discovered and applied the precipitin test by which it was possible to determine the species of animal from which the blood was derived. The precipitin test for blood had been used by the Home Office scientific analysts since 1908, and had proved of great value. Since then it had become possible to say from the examination of a stain from what human group the blood was derived. Blood grouping had already been applied in a medico-legal case in this country by Dr. Walker Hill, and might even be used in cases of alleged paternity.

Wounds.—Sir Bernard Spilsbury's Lettsomian lectures (1925) on Wounds and other Injuries in their Medico-legal Aspect gave an admirable account of the advances made in this direction. Wounds from firearms had received great attention recently, and it had been found that the rifling and marks inside the barrel of a pistol left a definite impression on the bullet fired. By this means it was often possible to say whether a discharged bullet had or had not been fired from a particular pistol. On this subject Prof. Sydney Smith, of Cairo, had done valuable research.

Ultra-violet rays in forensic investigations promised to be of great value. The fluorescing properties of certain substances often served for their immediate identification; thus difference in the composition of sealing-waxes was often at once shown when viewed under ultra-violet light. Kinds of paper which appeared similar under ordinary light were often seen to be different under ultra-violet light.

In conclusion, said Sir William Willcox, it should be remembered that toxicology and forensic medicine were really part of general medicine and intimately interwoven with it. They should not be kept in watertight compartments, and too great a differentiation was retrograde.

BOSCOMBE HOSPITAL EXTENSION.—The Prince of Wales recently visited Boscombe Hospital. In the newly opened extension he named the men's ward after himself, and congratulated Dr. C. H. Vernon, of the medical staff, who won the King's prize at Bisley this year. The extensions provide 50 beds for men and 50 for women.

ABERGELE SANATORIUM.—The Ministry of Health has intimated to the Public Health Committee of Manchester its approval of the extension of the Abergele Tuberculosis Hospital; the new block will accommodate 210 children, and will cost £134,000. This extension is part of a larger scheme which will ultimately provide 520 beds.

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY.

ANNUAL CONGRESS AT ROME, OCT. 12TH–16TH, 1927.

Prof. Umberto Gabbi, of the University of Parma, presided over the Congress this year, at which 14 nationalities were represented, with an attendance of 250 members and friends. The first three days, during which the Congress met in Rome, were divided between scientific business, public functions, and sight-seeing. At the outset an address of welcome was read in the Campidoglio by S. E. Pietro Fedele, Minister of Public Instruction, who was supported by Prince Potenziani, the Governor of Rome, the Dean of the Faculty of Medicine, and the Director-General of Public Health. Later in the day the members were received at the Palazzo Chigi by Signor Mussolini, and on the following day there was a reception at the Chamber of Deputies.

In the first discussion on the Use of Water in Acute Disease, Prof. GABBI (Parma) described his work on the nature of fever, which had led him to the conclusion that it must be considered rather in the nature of a grave danger to the organism than as nature's method of cure. He accordingly advocates hydrotherapy in preference to antipyretic drugs. Prof. ALOIS STRASSER (Vienna) dealt with the physiological and pathological principles underlying hydrotherapy, and described his attempts to estimate its value in promoting the excretion of toxins. While this rôle of the skin may have been overrated in the past, he regards the action of the skin on the immunobiological apparatus of the blood and hæmatopoietic system as a desirable field for research. Dr. FORTESCUE FOX (London) discussed and tabulated the acute conditions in which hydrotherapy is of proved value, referring in each case to the suitable technique. He divided the diseases he referred to into the acute febrile and acute *non*-febrile diseases, including in the latter category hæmorrhage into the stomach, brain or lung, migraine, Ménière's disease, and hyperthyroidism. Dr. C. E. SUNDELL (London) referred to the theory and technique of the "pyretic" treatment of acute rheumatism, basing his procedure on the assumption that acute rheumatism is not a "specific" disease in the sense that pneumonia and enteric fever are. A spirited discussion followed. Later, Prof. ASCOLI (Faculty of Medicine, Rome) read a paper on the baths of old Rome.

Members of the Congress were taken by special train to Montecatini, a watering-place situated between Florence and Pisa, well known formerly to English visitors, where they were received by Prof. QUEIROLO (Pisa), the honorary bath director. Papers were read on the biological action and therapeutic indications for thermo-mineral baths. Prof. VALENTI (Milan) considered that no single theory can account for the action of the various waters, since it is probable, he thinks, that the colloidal content may exert a fermentative action, whilst the absorption of gases, the contact action of saline particles and consequent ionic charges, have all to be taken into account. Prof. MARFORI (Naples) next spoke on the relation between the physico-chemical characters of various waters and their biological effect; this he has studied extensively in rabbits and dogs, finding certain constant modifications in the blood which depend on the tonicity of the saline employed. Dr. J. B. BURT (Buxton) gave an interesting paper on the differences between the action of thermal mineral waters and that of the simple hot bath, showing how the reactions differ in three essential characteristics—therapeutic effect, "bath reaction," and thermal debility. He discussed the causes for the differences observed, and put forward a plea for radio-activity as a possible explanation. He stressed the therapeutic importance of the skin, which, as he said, regulates the relations of the body with the outside world. He also compared the action of radio-active thermal waters with that of the ultra-violet rays.

On the next day the discussion was continued, and a paper was read by Prof. CHASSEVANT (Algiers) on the Electrical Phenomena of Medicinal Waters. He said that a medicinal water consists in a complex material held in a dispersing medium. The dissolved and suspended elements can be isolated and analysed, but their actual state can only be determined by estimating their physical conditions, amongst which electrical phenomena are pre-eminent. These methods render it possible to prepare a scale of ionisation, which is of considerable value in estimating the therapeutic activity of mineral waters. Mr. JOSEPH RACE (Buxton) discussed electrical phenomena under four headings—those of electrical conductivity, colloidal charge, hydrogen-ion concentration, and radio-activity. He explained the importance of each, and gave the results of recent attempts made in Buxton in connexion with the conservation of radio-activity in water. Dr. JUDD LEWIS (London and Tübingen) then put forward certain proposals in connexion with the adoption of international standards of measurement. He pleaded for agreement as to the manner of determining and expressing experimental data and for the presentation of these data to the physician in an acceptable and easily applicable form—e.g., the expression of the mineral content of a water as grains per 100 c.cm., this amount being equivalent to about half a tumblerful, and therefore a practical measurement from the point of view of the physician. A special committee was appointed by the society to deal with the matter more fully. The next paper, by Dr. PAUL FERREY-ROLLES (La Bourboule), dealt with the antitoxic and anaphylactic phenomena observed in connexion with medicinal waters. He showed that the natural immunity of animals may be raised, and quoted the belief of Billard that "every poison of organic origin can be rendered inactive by some water."

The final meeting-place of the Congress was Salsomaggiore, near Parma. Here the waters are subjected to several "processes" prior to being delivered to the baths, in contravention of the dictum of a distinguished hydrologist to the effect: "Mineral water, to be efficacious therapeutically, must be used in the state in which it leaves the earth, without being in any way modified chemically, and with as little difference in temperature as is possible." In Salsomaggiore salt is extracted on a commercial scale, as is iodine, whilst the petroleum content of the water, which is removed at the well-mouth, is sufficient to light the town. Prof. ZOIA (Milan), who opened the proceedings, gave, however, some striking instances of the beneficial effects of these waters in cases of chronic inflammation with exudation, in which he was borne out by the PRESIDENT. In particular he referred to the use of the dry salt inhalation, a method which is in advance of the ordinary vapour inhalation, and which is not used in England. In the afternoon a paper was read by Dr. A. MOUGEOT (Royat) on the action of waters on ferments and micro-organisms, during the course of which he showed that many medicinal waters were capable of sustaining the life of isolated cells, the cells chiefly used being red blood cells and spermatozoa, whilst sulphur water can be shown to have a marked bactericidal effect. The secretion of soluble ferments, which is a function of all cells, may be stimulated or inhibited by waters, whilst bicarbonate and sulphur waters have both a direct and indirect zymostheni action for amylases and oxydases. This zymostheni property is attributed to the electrolytes in the various waters. Mr. ARNOLD WOODMANSEY (Harrogate) terminated the proceedings of the Congress with a paper on the same subject, in which he stated that three standard types of organism (*B. coli*, *Staphylococcus aureus*, *Strept. fæcalis*) were submitted to the action of Harrogate sulphur waters under standardised conditions of technique; the bactericidal action was evident in every case, but the rate varied with the strength of water employed. Iron water of various

strengths was also employed and appeared to have a tendency to selective action, the colon bacillus and staphylococcus being more affected than the streptococcus.

Several members of the Congress visited Parma, where they were shown round the University and new hospital, where the President, Prof. Gabbi, occupies the chair of clinical medicine.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.

ON Oct. 18th Prof. JOHN FRASER (Edinburgh) read a paper on

Superficial Pain as an Aid in the Differential Diagnosis of Abdominal Pain.

After alluding to the difficulty of accurately diagnosing many abdominal conditions, he pointed out that superficial pain in one or more of its manifestations might offer great assistance. He dealt particularly with two manifestations of superficial pain: (1) hyperalgesia or hyperæsthesia, and (2) referred pain. Hyperæsthesia and hyperalgesia were explained as depending upon an irritability of certain spinal areas, the irritability having arisen as the result of certain afferent abnormal stimuli transmitted from the deranged viscus. The reception of a second somatic afferent impulse from the superficies corresponding to the excited spinal segments was apt to be magnified or altered so as to be represented to the sensorium as a hyperalgesia or a hyperæsthesia. Prof. Fraser found the most striking manifestation of the sign in connexion with infection of the gall-bladder and with appendicitis, in which it had been found in 58 per cent. of cases. The distribution was remarkably constant—namely, over the area described as Sherren's triangle, the distribution of the tenth and eleventh dorsal nerves. A great variety of factors might explain the incidence of the sign, and there was evidence that the responsible stimulus arose early in the pathological sequence, and that it might consist of stimulation of the mucous surface of the affected organ. Some of the most distinctive records arose from cases in which there were threadworms and concretions in the appendix. In gall-bladder disease the sign was more likely to be associated with small mobile stones than with a single large fixed stone.

The explanation of referred pain commonly accepted, said Prof. Fraser, was the projection to the surface by a disturbed sensorium of stimuli originally recorded as afferent impulses from a disturbed viscus. Apparent referred pain was more constantly present than hyperalgesia and hyperæsthesia, but it was very difficult to distinguish true referred pain. The paper ended with a reference to the problem of local tenderness and the interpretation of muscular rigidity as a manifestation of underlying visceral disease.

MILK BY GLASS TANK.—The London Midland and Scottish Railway, in conjunction with a large wholesale milk firm, are bringing into use a glass-lined tank for the conveyance of milk. The tanks, fixed on steel undercarriages, are insulated against fluctuations in temperature, so that the milk will reach its destination in good condition. Each tank holds 3000 gallons, and does the work of three ordinary milk vans. Something like 100,000,000 gallons of milk are carried annually by the railway.

SHEFFIELD HOSPITALS.—During a visit to Sheffield last week in which he visited numerous Poor-law institutions, Mr. Chamberlain, the Minister of Health, opened the corporation's new maternity and child welfare centre and a new out-patient department at the Sheffield Royal Hospital. In his speech on the latter occasion he advocated closer coöperation between hospitals and the general practitioners who send patients to them. Last week also, Lord Cave, the Lord Chancellor, opened Norton Hall as an auxiliary of the Jessop Hospital, Sheffield.

Reviews and Notices of Books.

THEORY OF PERCEPTION.

An Introduction to the Theory of Perception. By Sir JOHN HERBERT PARSONS, C.B.E., D.Sc., F.R.C.S., F.R.S., Ophthalmic Surgeon, University College Hospital. Cambridge: University Press. 1927. Pp. 254. 18*s*.

ONE aim of the author is to bridge the gap between the neural and the psychological by considering the phenomena of perception. Ambitious as such an aim may appear, it is by no means either impracticable or elusive, for the reader is informed at the outset of the author's "creed"—viz., that the doctrine of emergent evolution, as set forth by Lloyd Morgan, provides the stepping-stones whereby to pass without discomfort or straining of effort from one stage to another over the general stream of vital activities. The postulate is to the effect that from the combinations of elements of a given series new things arise of a different order, not to be foreseen by contemplation only of the original constituents of the combinations. Applying the hypothesis to the problem before him, Sir John Parsons can discover no hiatus as between the emergence of life at a given stage in evolution from matter, and the emergence of consciousness still later. Indeed, his problem is facilitated by discussion of what exactly is implied in the terms "consciousness" and "perception." For, clearly, he is inclined to see in stimulation of the simple receptor mechanisms of the lowliest organism the emergence of a state of "awareness" of a change in the environment, and in the tingeing of this awareness with an affective and cognitive element, however minimal, the emergence of something comparable to a perceiving consciousness. Thus even at the level of reflex activity are introduced traces of the sentience and the conation of the animal who, advanced in the scale is admittedly furnished with mechanisms the functions of which are associated with processes commonly called psychical. Once such suppositions are accepted the way is smooth; from this germ of response to stimulus the final flower of ideation and conceptual consciousness springs and reaches maturity.

The general hypothesis thus outlined is supported by a wealth of data drawn from various fields of biological and neural activity and illustrated by apt comparisons. From it the author passes to a study of the afferent nervous system viewed directly and comparatively, in particular of the systems of common sensibility and of vision. This study is well done, although from the standpoint of neurology certain statements relied on by the author in support of his theory might be traversed. He evidently accepts evidence suggesting the existence of a dual sensory system, but his conception of it is that neither of Head nor of Foerster. He distinguishes a dyscritic or primitive stage of little differentiation and little discrimination from an epicritic stage which permits of differentiation; one system persists alongside the other in most of the senses even of the highest animals. Pain, however, according to Sir John Parsons, exhibits no duality, and its mechanisms are not represented in the cortex. Not a little clinical and other evidence might be advanced against the view that the thalamus is a *terminus ad quem* of the primitive sensory system, and that in no circumstances can pain experience be cortical.

Other considerable sections of the volume are concerned with what appear to be side-issues, for instance, investigation of posture and attitude, and morphological descriptions of the comparative anatomy of the midbrain and basal ganglia. The final sections, on the visual system, take the reader back to the main thesis of the book and are conspicuously lucid even if highly technical. Incidentally discussion ranges over a number of minor if cognate questions arising out of perception in still other of the sense fields.

NEUROLOGICAL SEMIOLOGY.

Sémiologie des Affections du Système Nerveux. By Prof. J. DEJERINE. Paris: Masson et Cie. 1926. With 560 illustrations, many in colour, and three plates. Pp. 1219. Fr.190.

THE classical treatise on neurological semiology by the late Prof. J. Dejerine, long out of print, is often asked for. The present edition is an exact replica of the issue of 1914, that fine expression of the author's genius and labours. Glancing through its familiar pages again, we note how little, comparatively speaking, calls for modification, and are impressed once more with the clinico-pathological method of the French school and with its patent advantages. Perhaps its chief disadvantage is that it is weak in regard to the physiological interpretation of clinical syndromes; it legitimately associated symptoms with lesions, yet it rather fails to explain how the former must arise through mechanisms that are in action, not destroyed. Dead mechanisms are functionless.

A new generation is arising in neurology, and we commend to their interest this superb production, which those who have known Dejerine consider the work of a master.

PATHOGENESIS OF THE NEUROSES.

Das Neurosenproblem, vom lebenswissenschaftlichen Standpunkt aus. By Dr. EDGAR LEYSER, Privatdozent for Psychiatry and Neurology, Giessen. Berlin: S. Karger. 1927. Pp. 64. M.3.20.

THIS is a readable little essay on the pathogenesis of the neuroses, considered in a biological framework. Sensations, feelings, and fantasies are psychical processes which can enter the field of consciousness; the latter two in particular, representing as they do the undercurrents of emotion, are largely responsible for neurosis-formation, since in certain circumstances they may lead to a conflict between inclination and duty. Neurotic symptoms are in reality the outward expression of clashing feelings, and their prognosis depends on the fate or outcome of the rivalry. Treatment will prove efficacious if it is devoted to developing new emotional combinations, to checking and counteracting the old, and to establishing other aims in life. Thus will the wounds resulting from an antagonism of feeling-trends be healed.

AN INTRODUCTION TO NEUROLOGY.

Fourth edition, thoroughly revised. By C. JUDSON HERRICK, Professor of Neurology in the University of Chicago. London and Philadelphia: W. B. Saunders Company. 1927. Pp. 406. 12*s.* 6*d.*

POSSIBLY no book comparable in subject and in dimensions contains so much of the pure meat of neurological doctrine as does this modestly entitled "Introduction," which we have reviewed on previous occasions with due appreciation of its admirable qualities. Elementary enough for the tyro, it nevertheless adroitly manages to lead him by easy stages into deeper water without his ever becoming conscious of being out of his depth. Few writers on technical subjects exhibit such a desirable combination of knowledge and of skill, or art—whichever it be. Prof. Judson Herrick draws on zoology, anatomy and comparative anatomy, physiology, comparative physiology and psychology, with equal ease and directness, to present to his reader the nervous system as a working mechanism, from the lowest levels of reflex action to the highest complexities of behaviour.

A scholarly handling of wide-ranging material and a philosophic interpretation of diverse data combine to render this "Introduction" outstanding. If the student works from it and learns its principles no less than its facts he will indeed have gone a long way towards a scientific and practical knowledge of the most important system of the human frame.

A SYNOPSIS OF SURGERY.

Eighth edition. By ERNEST W. HEY GROVES, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng., Surgeon to the Bristol General Hospital; Professor of Surgery, Bristol University. Bristol: John Wright and Sons, Ltd. 1927. Pp. 674. 17*s.* 6*d.*

WHEN the eighth edition of a book is called for there can be no question of its popularity and success in the past. With the inevitable increase in size and the changes necessitated by the advance of knowledge, it is not, however, always possible to preserve those characters which made such a strong appeal in the earlier editions. A careful examination of the volume before us shows no evidence of flagging interest on the part of the author, and every sign of careful revision and successful effort to maintain the original conception. The information contained in the synopsis, whilst condensed and tabulated to a degree, is reliable, up to date, and complete.

LIGHT TREATMENT IN SURGERY.

By Dr. O. BERNHARD (St. Moritz). Translated from the German by R. KING BROWN, B.A., M.D., D.P.H., Medical Officer of Health, Bermondsey; Lecturer in Public Health, Guy's Hospital Medical School. London: Edward Arnold and Co. 1927. Pp. 317. 21*s.*

IN this book justice is at last done to a pioneer of heliotherapy. For more than 30 years Dr. Bernhard has been applying the good sunshine of the Engadin in his surgical practice and the results are here set out in Dr. King Brown's excellent translation. The book opens with a historical review of light treatment, which reveals the author's familiarity with the classics, whilst a section on light biology gives a good account of the action of light on plants, bacteria, animals, and man, with many original observations. Discussing the part played by pigment, Dr. Bernhard states that it is his impression that patients who pigment best are cured with the greatest certainty and speed with the sun-bath. The analgesic effect of the sun's rays is stressed, and the interesting observation made that light directly stimulates peristalsis, as was seen on exposure of bowel during a laparotomy or of fistulous and prolapsed intestine.

The injurious effects of light are fully set out in the section on pathology. The term "sun-fever" is applied to the acute inflammation with great redness of the skin and rise of temperature which may follow an injudicious first exposure. Diseases due to sensitisation, endogenous and exogenous, are also dealt with. Following a description of sunlight therapy, there is a section on treatment with artificial light. The quartz lamp is used by the author when sunlight is not available. In the chapter on indications for sunlight treatment in surgery, Dr. Bernhard states that it was the effect of sunlight on a badly healing wound that caused him to adopt the same treatment in sinuses and tuberculous ulcers. As a result of the successes obtained he began to treat closed tuberculous lesions. Favourable results obtained with ulcers, burns, and frost-bite are recorded, also the closing of fæcal fistulæ. Skin-grafts laid on dry granulating surfaces and exposed to the sun adhered firmly in 15 minutes, requiring no dressing.

"It is in surgical tuberculosis," Dr. Bernhard says, "that the greatest triumphs of sunlight treatment are obtained." All sufferers from this condition, even if there is only one focus of disease, are regarded as tuberculous individuals, and conservative treatment, especially in children, is urged. In comparing 302 cases, exposed to fresh air only, with 1163 cases treated with sunlight, he states that the duration of the healing process is shortened and operative interference less frequently necessary in the irradiated cases, though a few remained refractory to heliotherapy. The technique used is important. A strong local actinic and thermic stimulation is aimed at, and therefore local irradiation leading to pigmenta-

tion precedes general light-bath treatment. Major operative measures were used chiefly when, for economic reasons, it was found necessary to hasten a cure. The author states that at the present time his operative work is largely restricted to punctures, injections of iodoform emulsions, small incisions, scrapings, and special osteotomies. Many photographs illustrate the good results which Dr. Bernhard has obtained.

MALIGNANT TUMOURS.

Die Klinik der Bösartigen Geschwülste. By Geh. Rat. Dr. P. ZWEIFEL and Geh. Med. Rat. Prof. Dr. E. PAYR. Vol. III. Leipzig: S. Hirzel. 1927. Pp. 650. M.76.

THIS volume of a comprehensive work gives an account of the clinical features of malignant disease of the breast, and of the female generative organs. Much knowledge is collected between its covers, systematically arranged in the usual efficient German fashion, and well illustrated, a number of the pictures being in colours. Surgical and other methods of treatment are all fully described, including good accounts of X ray and radium therapy. There are interesting chapters on the vaccine treatment of cancer and malignant disease in animals. Appended to each section is a useful list of relevant publications.

URINARY SURGERY.

Second edition. By WILLIAM KNOX IRWIN, M.D., F.R.C.S. Edin., Surgeon to Out-patients, St. Paul's Hospital for Genito-Urinary Diseases. London: Baillière, Tindall and Cox. 1927. Pp. 271. 10*s.* 6*d.*

THIS is an enlarged edition of the author's surgical urology and is a useful little book for the practitioner. The subject is approached from the point of view of the most prominent symptoms, and although this method of describing disease has many drawbacks, yet the call for a new edition shows that the author has made a success of it. A new feature of this edition is outline descriptions of operative procedures.

EVERY WOMAN A NURSE.

By EDITH NEWSOME. London: Humphrey Milford, Oxford University Press. 1927. Pp. 204. 3*s.* 6*d.*

THIS small book is a revision of one published in 1916, having additional chapters on hygiene of children, on simple remedies, and on first aid; it is specially prepared for use in the home, for societies and schools. The chapters are good and the remarks on bandages should be exceptionally helpful to amateurs in sick nursing. Many of the illustrations, however, are inappropriate to home treatment, and terms are sometimes used and instructions given which would not be comprehended by the untrained. More information might perhaps have been given about the care of incipient tuberculosis.

HYGIENE AND PUBLIC HEALTH.

A Treatise on Hygiene and Public Health. Sixth edition. By BIRENDRA NATH GHOSH, F.R.F.P.S. Glasg., Examiner in Hygiene and Pharmacology, University of Calcutta and State Medical Faculty of Bengal. Calcutta: Scientific Publishing Co. 1927. Pp. 667. 10*s.*

THE author of this book justly claims that its usefulness has been increased by thorough revision and the introduction of a number of new subjects. No discovery of importance in relation to the practice of preventive medicine fails to receive some reference, and a special chapter on diet in India has been added. The result is as complete a survey of the field of public health as can be expected in a book of this size. The unevenness characteristic of such efforts at revision is noticeable. For instance, a fairly adequate statement of the modern conception of ventilation in the chapter on air is followed in the succeeding chapter by the repetition of the old idea that the amount of air required for ventilation largely depends on the amount of impurities present; and the idea that "diseases like cholera, enteric fever, erysipelas, measles, scarlet fever, &c., are aggravated by sewer gas" is surely obsolete. Generally speaking, the book follows the established lines of English short text-books on hygiene and sanitation, and, although frequent reference is made to the problems peculiar to India, it can hardly be said that it conveys in true perspective a picture of the field of hygiene in that Empire. It is, however, well put together and indexed, and is as good a short book on Indian hygiene as we have seen.

THE NORMAL DIET.

By W. D. SANSUM, M.S., M.D., Director of the Potter Metabolic Clinic, Santa Barbara, California. London: Henry Kimpton. 1927. Pp. 136. 6*s.* 6*d.*

IN this book Dr. Sansum discusses the basic principles to be considered in the selection of a normal diet, and provides an extensive series of menus which fulfil the required conditions. To appreciate it fully the reader must be familiar with such things as Lima bean muffins, frozen apricots, Chiote, Swiss chard, and summer squash. But for the initiated the function of the book is fully discharged.

OPHTHALMOLOGY.

A Handbook of Ophthalmology. By HUMPHREY NEAME, F.R.C.S., Ophthalmic Surgeon, University College Hospital; and F. A. WILLIAMSON-NOBLE, F.R.C.S., Assistant Ophthalmic Surgeon, St. Mary's Hospital. London: J. and A. Churchill. With 12 plates containing 41 coloured illustrations and 194 text-figures. 1927. Pp. 312. 12*s.* 6*d.*

STUDENTS attending the practice of an eye hospital or working in the ophthalmic department of a general hospital will find in this work a reliable guide to the examination of the eye and to the great bulk of eye diseases they are likely to meet. No claim to originality is made by the authors, and for the most part the teaching is in accordance with that of larger works, such as Fuchs's text-book. The newer methods of perimetry and of slit-lamp examination are not included, nor are rare diseases or unusual operations. The descriptions of the principal operations performed on the eye are easy to follow. In the chapter on cataract the relative advantages of simple extraction, extraction with complete iridectomy, and extraction with peripheral iridectomy are well set out. The operation recommended in favourable cases is simple extraction, on the ground that there is no chance of the lens capsule getting entangled in the lips of the wound. The book forms a good groundwork for the student fresh to the subject, and the figures enhance the value of the text. One of the most valuable features is the inclusion of 40 coloured illustrations, mostly of fundus conditions, from Hamblin's collection, all drawn from life by expert artists.

JOURNALS.

ARCHIVES DE MÉDECINE ET DE PHARMACIE NAVALES. Vol. CXVII., No. 2.—The current number relates of antimalarial work recently done in Italy at Porto Torres, in the north-west of Sardinia, by Médecin (Surgeon-Lieut.) Dr. Cluzel, of the French Navy. Porto Torres has only 6000 inhabitants, but considerable hydro-electric works in its neighbourhood were projected and increased export trade was hoped for. But the 60 per cent. incidence of malaria stood in the way. So an experimental antimalaria station was established on the spot by the Central Committee in

Rome, with the coöperation of the International Health Board of the Rockefeller Foundation. It appeared at once there were no sufficient funds for large works, so merely "piccola bonifica" was attempted. The staff of the experimental station comprised a doctor and a nurse, who were on duty all the year, and a sanitary engineer and two workmen, who operated from May to November, seven months. The doctor, when cases came or were brought to him, recorded their splenic indices, hæmoglobin percentages, and their particular malarial infections, and prescribed treatment, the rule being, for adults (and children according to their ages) for six days, 25 gr. of quinine daily, for the next 14 days 12 gr. every day, and 10 gr. daily for 40 days thereafter; unless they were then parasite-free the course was repeated. Thanks in part to the nurse, who takes round quinine and hunts up undeclared cases, patients come for treatment very regularly. The doctor also studies the growth of larvæ (for the identification of species), examines mosquitoes to determine the frequency of their infection, notes the proportions of males and females captured in places (males live at the spot where bred, but females travel), does precipitin reactions to decide with what blood females are gorged, takes the pH of the water in pools (for light on breeding possibilities and hindrances), colours live mosquitoes for identification of distances flown before recapture, and examines dead larvæ for Paris green (seen in their digestive tube). The engineer's work extends over a circle of 3-kilometre radius round Porto Torres, mosquitoes being thought not to fly farther, and he has this area mapped in sectors, regularly visited, with the larva-pools, as well as the usual shelters for adult mosquitoes—houses and stables—marked. The great breeding place is in the slow stream Turitano, 3 feet deep and from 4 to 20 yards wide, on which the town is built. If there was to be no drainage or clearing done, oiling would seem to be needed, but on account of expense Paris green was substituted. Treatment of the water every eight days keeps it quite free, and preliminary weed clearing is unnecessary. After 24 hours the poisonous particles sink to the bottom where they are dealt with by micro-organisms, and the water is harmless to men and cattle. The results are that anopheles have disappeared from the 3-kilometre circle, 7 (not 360) fresh cases of malaria occurred in the summer of 1926, and the expense in 1925 was 7*d.* per inhabitant. Oiling would have cost more in material and labour; clearing of the river's course would have been necessary, the water would have been spoiled for cattle, and the result could hardly have been bettered. Dr. Cluzel's is a valuable and exhaustive paper.

THE WEST AFRICAN MEDICAL JOURNAL.—A new medical journal is to be published quarterly from Lagos at an annual subscription of 20*s.* The colonial editors are, for Gambia and Sierra Leone, the Director, Medical and Sanitary Service, Freetown; for the Gold Coast, the Director, Medical Research Institute, Accra; and for Nigeria, the Director, Medical Research Institute, Lagos. The first issue consists of 12 pages composed for the most part of original contributions and illustrated by one excellently reproduced photographic plate of four surgical cases by Dr. Clive Sharp. The new journal is ushered in favourably, for it has as a prototype the *Kenya and East African Journal*, which is already well established. The aims of the editors go beyond the recording of official statistics and staff changes; they intend the new organ to assist in the knitting together of the personnel of a widely scattered service, many of whom by reason of space are unknown to one another, and in the encouragement, as one of the editorial staff says, "of that spirit of patient research and inquiry, that critical faculty, that desire for advancement of knowledge of disease which are our heritage from our great master, Patrick Manson." The aim is to make the journal a medium for the free and frequent exchange of ideas between the members of the staff and also between medical practitioners. Success should follow a venture wisely conceived.

Reports and Analytical Records

WEINBERG'S SPECIAL NO. 1 SIZE TURKISH CIGARETTES.

(MESSRS. WEINBERG, 3, CARLISLE-STREET, LONDON, W.)

THE box examined contained 25 cigarettes each weighing 1·63 grm. (25·1 gr.); approximately 17 cigarettes weigh 1 oz. The paper of each cigarette weighed 0·74 gr. On analysis the following results were obtained:

Moisture	.. 14·52 per cent.
Total ash	.. 15·56 „ „
containing sand ..	.. 2·46 „ „
Nicotine	.. 0·97 „ „

The paper of these large cigarettes is of good quality. The Turkish tobacco used in their manufacture is of a high grade and quite free from stalk and midrib. The cigarettes burn evenly and are cool to the throat. The percentage of nicotine is distinctly low.

MINTIPS.

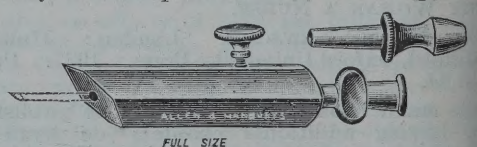
(MINTIPS, LTD., SLOUGH, BUCKS.)

MinTips is a "hard" sweet, opaque white in colour, convenient in size, and each piece is wrapped in waxed tissue paper. MinTips have a very pleasant refreshing mild flavour of peppermint. They dissolve slowly in the mouth, are not too sweet, and do not adhere to the palate. They have the effect of keeping the throat moist, and, in consequence, to some extent, are a preventive of thirst. Analysis reveals them as sweets of wholesomeness and purity.

New Inventions.

LONGITUDINAL SINUS WEDGE.

THE longitudinal sinus route in infants for intravenous injections or for the withdrawing of blood is frequently regarded as both dangerous and difficult. Various special needles and needle-holders have been devised to add to the safety of an extremely useful and easy little operation. The "wedge" here



FULL SIZE

shown is a modified form of various American appliances, but nothing of its kind (apart from specially devised needles) appears to have been hitherto available in this country, and most of the foreign "holders" seem too cumbersome or complicated. The use of the "wedge" with an ordinary needle is shown in the accompanying illustration. The length of needle projecting is judged roughly by pinching up the infant's scalp and thus estimating its thickness. The needle is introduced point backwards into the longitudinal sinus at the posterior angle of the anterior fontanelle, and the flat bevel edge rests on the bony margins at this point. For the withdrawal of blood or the introduction of small amounts of fluid an ordinary Record syringe can be attached to the needle, but where a saline transfusion apparatus is being used it is essential to have some sort of adapter, such as the one illustrated, facilitating connexion between rubber tubing and needle. In the case of transfusion blood should be allowed to escape from the needle before the adapter is fixed.

The "wedge" was first made over two years ago for use at the Hospital for Sick Children, Great Ormond-street, and is now obtainable from Messrs. Allen and Hanburys, 48, Wigmore-street, W.

ALAN MONCRIEFF, M.D., M.R.C.P. Lond.

THE LANCET.

LONDON, SATURDAY, NOVEMBER 5, 1927.

THE ACTION OF LIVER IN PERNICIOUS ANÆMIA.

A PAPER contributed to our present issue by Dr. J. H. ANDERSON and Dr. E. I. SPRIGGS draws attention again to the encouraging results attributed to the Minot-Murphy diet in the treatment of pernicious anæmia. Though these results raise a hope that we may at last have an effective weapon against this hitherto fatal disease, lapse of time alone can decide its full value, and it is well not only to remember the dramatic relapses and remissions natural to the condition, but to consider also our almost complete ignorance of the rationale of the new treatment. The therapeutic action of liver does not seem to be specific for pernicious anæmia, for it is also observed in the experimental secondary anæmias of animals and in sprue. The morbid states of sprue and Addisonian anæmia may in exceptional cases come to resemble each other so closely as to be indistinguishable, and of recent years the same ætiological agent, yeast, has been ascribed to both. Yet there can be little doubt that sprue is a clinical entity, and distinct from pernicious anæmia, in spite of the facts that the two conditions are accompanied by a glossitis of similar type, and that achylia, together with the symptoms (if not the physical signs) of spinal cord changes, and the characteristic blood picture of pernicious anæmia, may occur also in sprue. For whilst achylia, severe anæmia, and, to a lesser degree, changes in the cord, are almost constant in Addisonian anæmia, they occur only as somewhat exceptional accidents in the long drawn-out course of sprue. We know that various forms of anæmia due to internal hæmolysis, whether consecutive to the inhalation of benziuretted hydrogen gas, the harbouring of the *Dibothriocephalus latus* parasite, or the morbid syndrome of pernicious anæmia, may produce an identical blood picture, and it is evident that we cannot deduce from a similar blood state a common causative factor.

Liver soup has been used for many years in the treatment of sprue, as Dr. G. CARMICHAEL LOW and Dr. W. E. COOKE point out in the paper which appears on p. 960; but the use of liver for the cure of the anæmia has only received due recognition as a sequel to our acquaintance with its effect in pernicious anæmia. The fact that its effect is not specific suggests that the therapeutic substance it contains is not of the nature of an antibody to the infecting agent, but rather that it acts as a general stimulant to blood formation, as do iron and hæmoglobin, or possibly that normal liver supplies a substance or substances which in certain morbid states are deficient. Such conceptions are strengthened by the apparent necessity for continuing its administration indefinitely, since—up to a period of three years, at any rate—relapses may occur if the treatment is stopped. That liver acts by merely stimulating the marrow it is clear that its effect cannot be due to the iron or hæmoglobin which it contains, for a liver fraction has been separated which is said to be equally effective, although almost free from protein and iron. Further, in pernicious anæmia a constant and noteworthy effect of liver treatment is the rapid disappearance of the glossitis, and it is also claimed that the cord symptoms improve or fail to develop. It is difficult to correlate these effects either with the marrow-stimulant conception, or with the theory of G. H. WHIPPLE and F. ROBSCHEIT-ROBBINS that pernicious anæmia is a deficiency disorder due to lack of some essential in the stroma of the red cells, unless we assume that the damage to the cord and buccal lining is done by the products of hæmolysis rather than by the hæmolytic agent itself.

The evidence that internal hæmolysis is the main underlying factor in pernicious anæmia appears to be almost overwhelming. The widely accepted theory that the hæmolytic agent is derived from bacteria which gain entrance by the mouth to the intestine owing to the absence of an effective gastric juice, has been ardently supported on somewhat loose circumstantial evidence, but necessarily lacks the solid basis of direct proof. The main bacteriological agents implicated have been hæmolytic streptococci, yeasts, and the *Bacillus welchii*. The arguments in favour of the intestinal toxin theory are summarised on p. 961 by Dr. STANLEY DAVIDSON, who adduces evidence involving the *B. welchii*, and advances our conception of the ætiology of pernicious anæmia a stage further by supposing a breakdown in the detoxicating function of the liver. According to this view the chain of events would be achylia, increase of the intestinal flora, and, in particular, of *B. welchii*, followed in certain cases by liver failure and the unrestricted action of the toxin upon the blood. Such a conception has the advantage of simplicity, but it must be admitted that our knowledge of the detoxicating action of the liver is mainly confined to its effect upon phenol, and that even if the liver has the power of neutralising bacterial toxin derived from the intestine it is hard to believe that such action can be replaced by the administration of cooked liver by the mouth. It should be remembered, too, that eminent investigators are still producing evidence in favour of the belief that pernicious anæmia is a state of faulty blood construction and not a hæmolytic disorder. Should the liver treatment, as we hope, stand the test of time it will not only mark an advance in treatment, but should throw light upon the ætiology of an obscure malady. At the moment it appears difficult to reconcile its effect with our two main conceptions of the underlying cause of the disease, but further knowledge of the nature and mode of action of the liver substance may help us to decide which conception is the right one, unless indeed both are wrong.

THE DIAGNOSIS OF POLIOMYELITIS.

IT is never a good thing for a disease to be popularly known by the name of its final and least curable stage, and it is well that the term "poliomyelitis" is steadily replacing the older "infantile paralysis." Although cases without paralysis were described by C. S. CAVERLY, of Vermont, as long ago as 1894, and although absolute paralysis occurs in less than 20 per cent. of cases, yet the early diagnosis of the condition in its systemic and susceptible phase is a comparatively recent achievement. Indeed, Dr. F. M. R. WALSHE, in the discussion at the Medical Society of London last February, declared that "unless in the presence of an epidemic, or of well-developed general and meningeal reactions with the characteristic intermission between them, diagnosis before the appearance of paralysis is likely to remain exceptional."[1] If the disease is to be tackled successfully,

[1] THE LANCET, 1927, i., 327.

however, early and yet earlier diagnosis is essential, and it is encouraging to find a slightly more optimistic view taken by Dr. J. P. LEAKE in a recent number (Oct. 7th) of the *Public Health Reports* of the U.S. Public Health Service. His paper appears between a paragraph recording 4570 cases of poliomyelitis, reported in the United States between July 3rd and Oct. 1st, and a table showing the steady increase in its incidence from January to September of this year.

Dr. LEAKE follows Dr. WALSHE in classifying the stages into three: systemic, meningitic, and paralytic. He admits that diagnosis in the first phase can only be a matter of probability. He stresses two features which were noted in the Broadstairs outbreak—constipation and retention of urine. Other observers, however, have found diarrhœa more common than constipation. A curious contrast to many systemic infections is found in the rarity of convulsions, while the absence of herpes labialis helps to distinguish poliomyelitis from epidemic meningitis. Dr. LEAKE concludes that, if there is an epidemic in the neighbourhood, a tentative diagnosis of poliomyelitis is justified by fever, vomiting, constipation, drowsiness, and irritability, especially when these are combined with headache, transient flushing, abnormal sweating, and retention of urine. The usual moderate leucocytosis may be replaced by a leucopenia. With the onset of meningeal symptoms we are admittedly on firmer ground, and Dr. LEAKE maintains that systemic symptoms combined with pain or resistance on spinal flexion, local hyperæsthesia, and tremor, would be sufficient for a presumptive diagnosis of poliomyelitis in the absence of signs more indicative of some other disease. In common with most American observers, he relies on the pain and stiffening elicited by an attempt to lift the child with one arm under its flexed knees and the other under its neck. A very persistent symptom, in his experience, is popliteal pain, due to hypertonicity of the hamstring muscles. Examination of the cerebro-spinal fluid is of such value that 100 per cent. accurate diagnosis from it has been claimed. Dr. LEAKE, however, disagrees with Dr. JAMES COLLIER that lumbar puncture "does no harm,"[2] and regards the danger of subarachnoid hæmorrhage as so great in unskilled hands that he deprecates the operation as a means of diagnosis. History and thorough examination will, he says, afford quite as reliable an indication of the condition. The hyperæsthesia may be cutaneous, muscular or articular, and is apt to be mistaken for rheumatic pain. It is, however, unaccompanied by swelling, and involves areas corresponding to segments of the spinal cord. Anæsthesia is rare, and if present at all is local and inconspicuous. Tremor, brought out by muscular action or the extension of unsupported limbs, is characteristic, and unsteadiness in action and gait may amount to ataxia. In the irritative stage the reflexes are irregularly increased, and a diminution is the first sign of degenerative changes in the peripheral motor neuron. Even with the minor reflexes a constant discrepancy between the two sides is significant. The lumbar and epigastric reflexes should not be forgotten, as they may give a hint of incipient paralyses in the dorsal and abdominal muscles. The gluteal, scapular, pectoral, cremasteric, and plantar reflexes are also useful.

Dr. LEAKE gives some useful hints on the technique of examination, reminding the practitioner of the advisability of keeping a pain-test until the end with small children, and of the importance of obtaining confidence. Reflexes must be tested repeatedly, under the most favourable conditions, and may require reinforcement. The conventional patella-hammer is, he says, useless for eliciting deep reflexes, and a special one should be improvised from stout wire and two soft rubber erasers, one 2½ in. by ⅝ in. by ⅜ in., for small babies, and the other 2⅜ in. by 1¾ in. by ½ in. One end may be bevelled with a sharp knife to give precision. The knee-jerk should be elicited in the recumbent position, with the knee semi-extended at an angle of 120°; the doctor's hand on the thigh ascertains the response of the muscle. Half a wooden tongue-depressor, broken diagonally, is better than a pin for testing superficial reflexes. All the movements of the limbs should be tested repeatedly to detect lack of tonus and of resistive efforts, which may be very definite even in the tiny baby. The enthusiast must not forget, however, that in the acute stage the child's chief need is rest in bed, and to make a sick child walk across the room is to defeat the end in view. Usually the examination can be divided over several visits. In Dr. LEAKE's concluding words: "The diagnosis of poliomyelitis is not a simple matter, depending on a single factor or sign, but the whole history and physical examination must be taken into consideration; and when that is done, there are enough idiosyncrasies and predilections of the disease to enable a diagnosis to be made with as great certainty as is usual in the diagnosis of other diseases, even without what was formerly considered the essential feature of the malady—permanent paralysis."

RETIREMENTS IN THE PUBLIC HEALTH SERVICE.

Two medical officers of health have recently retired after long service in metropolitan boroughs.

Dr. H. R. KENWOOD became medical officer for Stoke Newington on Sept. 30th, 1894, after having held a similar position at Finchley. His 33 years' tenure of office gave ample scope to a gift of sound administration and the opportunity of pioneer work in several directions. Stoke Newington was the first metropolitan borough to provide (in 1900) for the voluntary notification of phthisis. By 1907, when child welfare centres were almost unknown, Dr. KENWOOD had established a centre in the borough and had enlisted the assistance of a body of voluntary workers. As the result of a series of local experiments Stoke Newington was the first sanitary authority in the country to use formaldehyde for the surface disinfection of rooms in lieu of sulphurous acid. In 1901, as the result of tests made on himself, Dr. KENWOOD took a strong line against the addition of chemical preservatives to food and succeeded in getting their use appreciably reduced in his area. Three years later he became Chadwick Professor of Hygiene in the University of London. During the war period, when he became one of the three civilian sanitary advisers to the Army Council, he was still able to continue his local public health work and proceeded to organise a creche with valuable results. His influence in the public health world extended far beyond the boundaries of his area, the administration of which, however, provided him with opportunities for keeping in touch with the everyday problems of sanitation and of maintaining a salutary sense of proportion in hygienic work. Prof. KENWOOD's term of service was honoured at a complimentary dinner given at the Connaught Rooms on Oct. 6th, when he was presented with an illuminated address, and in replying to the toast of his health remarked on the welcome growth in recent years of the community impulse towards health.

Dr. JOSEPH PRIESTLEY entered upon his public duties in Lambeth on June 27th, 1895, and relinquished them at the end of last month. He gained experience at Camberwell and Leicester before serving for 32 years as chief officer of the public health depart-

ment to one of the largest boroughs of the metropolis. Here he was successful in building up a satisfactory health unit. Not only did he supervise with extreme conscientiousness what is perhaps the most troublesome and difficult sanitary work of a metropolitan borough—namely, the housing of the people—and strive to the utmost to keep up a satisfactory standard, but he devoted much time and thought to the administration of the tuberculosis dispensaries. Owing to Dr. PRIESTLEY the public health equipment of Lambeth is singularly complete. There is a municipal maternity home, a municipal milk depôt, and a municipal bacteriological laboratory. All this work was achieved with a minimum amount of friction; he was esteemed a very courteous official by his Council. Of late years his reputation was enhanced by a piece of epidemiological work which has now become a classic—the tracing of a local outbreak of food poisoning in South London to a paratyphoid carrier. Dr. PRIESTLEY holds the highest position in the esteem of his public health colleagues, and for some years was elected one of the two hon. secretaries of the Society of Medical Officers of Health. He was honoured on Oct. 27th at the Lambeth Town Hall by a presentation from his fellow practitioners. On this occasion Dr. PRIESTLEY remarked upon the decrease during his term of office of the general death-rate in Lambeth from 19·5 to 11·5 and of the infantile mortality from 152 per 1000 births to 38·4, but he disclaimed credit and responsibility for the fall of the birth-rate during the same period from 31·9 to 24·1. "All I have been able to do," he said, "has been to counteract the bad effects of this lessening of the birth-rate by a correspondingly greater lessening of the mortality-rates, leaving a net balance to the good so far as Lambeth is concerned."

Annotations.

"Ne quid nimis."

THE ÆTIOLOGY OF MEASLES.

THE search for the causal agent of measles is still being actively pursued, and at the recent meeting of the American Medical Association William E. Cary and Lois H. Day, of Chicago, reported the isolation of a small green-producing, Gram-positive, short-chained streptococcus from the tonsillar secretion of 93 out of 98 patients who were in the early eruptive stage of the disease. The organism, they say,[1] grows well aerobically in 24 hours, producing a green surrounding zone three times the size of the colony. This green-producing coccus persists in the throat after the patient ceases to be contagious epidemiologically, but the type of colony which it produces changes definitely as the patient's temperature becomes normal. Berkefeld filtrates of throat washings, when injected into rabbits, produce a rise of temperature from 0·8–3° F., and a distinct rash is said to have been noted in one case. In one rabbit cardiac puncture yielded a pure culture of a green-producing diplococcus; in others a similar organism could be cultivated from the blood; whilst in 11 out of 21 cases the coccus was isolated from the conjunctival secretions. Large amounts (10 c.cm.) of whole-broth cultures of the organism injected intratracheally or intravenously cause a slight rise of temperature and a definite erythematous rash. Fermentation tests showed that acid production in salicin, while not invariably produced, is of value in differentiating the organism. Agglutination tests with the serum of patients convalescent from measles, and with strains of the green-producing diplococcus, have very indifferent results. Tests with the filtrates of broth cultures of the organism on the lines of the Dick reaction have not yielded consistent results.

In a discussion on the above results, Dr. W. H. Park, of New York, said that his experiments with the organisms isolated by Ruth Tunnicliff and by Ferry and Fisher, lead him to believe that these cocci were only concomitant organisms, and not the causal agents of measles. He thinks that measles is due to a real filtrable virus, and not to any organism of the size of the green-producing streptococcus. His experiments with Tunnicliff's toxin have not shown any distinctive difference in the cutaneous reactions of those who have had measles and those who have not. Dr. W. T. Harrison, of Washington, D.C., said that he had been working with Dr. R. Degkwitz in Pfaundler's clinic in Munich, and gave an interesting description of Degkwitz's recent work. Material from the nose and throat was inoculated into dilute human plasma and incubated overnight, and the culture was filtered through a Berkefeld N filter. The filtrate was inoculated into human blood plasma diluted 1 in 7, and rendered semi-solid by the addition of calcium chloride. Transfers to fresh medium were made every six days, sheep serum being added to the medium, and the proportion increased at each transfer, so that at the fourth subplant sheep serum alone was used. The green-producing diplococcus of Tunnicliff was used in alternate cultures as a symbiont. At the third transfer the Berkefeld filtrate of the culture was inoculated into monkeys which later developed febrile symptoms. The blood from these animals was inoculated into further monkeys, and the transmission was accomplished to the fourth generation. The serum of the recovered monkeys was used in protection experiments on susceptible children, and protection was conferred in every case. Normal monkey serum had no such effect.

There is still a bewildering array of micro-organisms of various sizes, each regarded as the causal agent of measles, and more work is needed before the actual incitant of the disease can be identified with certainty.

THE EXPLOITS OF A CAVALRY FIELD AMBULANCE.

THE rapid advance of the cavalry which opened Lord Allenby's victorious campaign in Palestine in September, 1918, involved great difficulties for the field ambulances of the swiftly moving cavalry brigades, only met by the wise foresight of the commanding officers, and the devoted work of other ranks and followers. It is instructive to read, in the *Journal of the Royal Army Medical Corps* for September (p. 161), the account by Lieut.-Colonel H. F. Humphreys, M.C., of how all difficulties were successfully met. These must have been great where a combined (British and Indian) field ambulance was in question, with no I.M.S. officer, no European who could talk Hindustani, none who could understand the Egyptian camel drivers. The intended operations were not disclosed until Sept. 17th at Ramleh, when reorganisation had to be completed, necessary stores decided and drawn, and camels and remounts obtained, all within two anxious days. The unit was divided into a mobile (bearer and tent) section and another, less mobile, to be a divisional clearing station. The tent and bearer sections marched from Selmé at 6 A.M. on Sept. 19th to Beisan, doing the 90 miles in 38 hours, and arriving complete. The heroes of this march were the 24 donkeys which, carrying each an Indian follower, had themselves no one casualty, not even a sore back. On Sept. 25th the bearer section marched off across the Jordan with the brigade for Damascus through the desert. The tent section, left behind to evacuate sick and wounded to Haifa, followed next day, without guard or convoy, rejoining most creditably at Damascus on Oct. 2nd. But it is the camel convoy which gets the highest praise, 20 camels, their drivers all Egyptians, with but one British soldier, Private R. A. Gibbs, R.A.M.C., and he in command. The convoy marched by itself three days through the desert, without map, compass, guide, or guard or arms, among marauding Arabs and Turkish stragglers, and rejoined at Damascus on Oct. 4th. When supplies ran short Gibbs traded,

at the villages, discarded Turkish equipment he had collected, such as boots, and so got camel fodder, eggs and milk. He defended his convoy once with a Turkish rifle and ammunition he had picked up. We are glad to see he got the Military Medal. As Colonel Humphreys remarks, the responsibility that may fall in war on a private, R.A.M.C., requires they shall all be Class A men. An outburst of malaria began at Damascus about Oct. 3rd, and on 4th, 5th, and 6th 200 cases passed through the mobile section of the ambulance, which marched on and reached Baalbek on the 15th. It evacuated cases to Damascus till Oct. 12th, and thereafter to Beyrout. Altogether, though itself crippled with malaria, it dealt with 1307 casualties in October, 90 per cent. of them malarial. The less mobile section marched up by the Sea of Galilee, losing heavily by malaria, indeed two-thirds of its British personnel, the commanding officer (Captain S. R. K. Thomson) having to drive a wagon. In five weeks to Oct. 31st this section took in 1314 cases. It ultimately rejoined headquarters at Baalbek on Nov. 9th. Individuals as we have seen did well. When so many in a unit are exceptionally efficient much praise must be due to the leading of the commanding officer. Colonel Humphrey's story of the campaign is well worth reading.

THE CONCENTRATION OF HÆMOGLOBIN IN THE BLOOD.

IT has been well known for a long time that exposure to low oxygen pressures results in an increase in the quantity of red cells and hæmoglobin per unit volume of blood, and the observations of Haldane and Douglas on Pikes Peak showed that this high altitude polycythæmia was due, not to a concentration of the blood, but to the production of many new red corpuscles as a compensatory hypertrophy. It is not so clearly recognised that breathing atmospheres containing excess of oxygen leads to a diminution in the red cells and hæmoglobin. Doyon and Morel [1] showed long ago that rabbits kept in a caisson in compressed air for three weeks became anæmic, and Dr. J. A. Campbell in two recent papers [2] has produced more ample evidence. He worked with monkeys, rabbits, guinea-pigs, rats, and mice exposed to air containing about 50 per cent. oxygen at atmospheric pressure and found that the percentage of hæmoglobin fell by a quarter to a third—the details differing a good deal in the various experiments. The number of red cells per cubic millimetre and the percentage of hæmoglobin are, then, functions of the oxygen supply, and what we call the "normal" figures depend on the accident that most of us live in an atmosphere containing 21 per cent. of oxygen at a pressure of about 760 mm. of mercury. The "normal" hæmoglobinometer figure for people living high up in the Andes is perhaps 130 per cent. on the ordinary scale; if anyone could get deep enough into the earth to have the air pressure doubled or lived in some place where the air had twice the ordinary amount of oxygen, the "normal" figure would no doubt be 80 per cent. or thereabouts. The facts indeed make one wonder whether after all the environment we live in is as good as it might be. Hæmoglobin is not much use unless it goes round the body, and the trouble about sending a great deal of it round the body quickly enough is that the red cells in which it must be carried make the blood inconveniently viscous. The polycythæmia of high altitudes passes off quickly enough on returning to sea-level; the body does not like it because it throws more strain on the heart. Similarly, the polycythæmia produced by transfusion is soon corrected by arousing an active destruction of the red cells which the body can do without.

We judge therefore that the "normal" concentration of red cells is a compromise between the oxygen supply and the work of the heart; it presumably represents the least viscous fluid which will carry the minimum necessary amount of oxygen. And it would seem to follow that we should do better if our air contained 40 or 50 per cent. of oxygen instead of 21 per cent. Atmospheres of anything near pure oxygen are well known to be harmful if breathed for any length of time, but there is no evidence in Dr. Campbell's experiments or elsewhere that doubling the ordinary amount would do any harm. Extra oxygen improves the physical capacity of normal people over short periods, as Dr. Leonard Hill showed. But continued life in it would lead to a relative anæmia, the oxygen supply to the tissues would remain where it was, and the benefit which would accrue would come from putting the heart in the easy position which we now give it by lying down. Perhaps it, too, would grow smaller.

Dr. Campbell also gives some very interesting data about the colour-index. In animals which become polycythæmic from diminution of oxygen there is the diminution of the colour-index which usually accompanies active blood formation, but it rises considerably in those which become relatively anæmic from living in high oxygen pressures. There seems no other explanation of this than to assume that the red cells normally present in the blood are on the average immature; if the demand for red cells is diminished there is time for them to develop fully before they come into the circulation. This interpretation is consonant with the facts that a continual need for fresh red corpuscles is associated with either a low colour-index or histological evidence of active regeneration or both. As Prof. Barcroft's expedition to Peru showed, reticulated cells are continually present in the blood of natives living their whole lives at those high altitudes. Immature corpuscles are regularly to be found in small animals like rats and mice which live a shorter time and at a much higher rate than man. A rabbit normally has a colour-index of about 0·7 on the human scale. It seems likely that the really mature red cell contains a good deal more hæmoglobin than we have suspected. A similar rise in colour-index was reported in cases of hunger œdema in Germany during the war, due presumably to the difficulty of making new cells.

PLAGUE EPIDEMICS IN THE PAST.

ALL epidemics bring out at once the best and the worst of human nature, but in the records of plague epidemics of the past nothing stands out more forcibly than the hopeless despair of both those attacked and those who expected to be. During the great epidemic of 1348, for instance, there was living in a Franciscan house at Kilkenny a friar by name John Clyn, who kept a chronicle which has come down to us. He notes in very simple language the progress of the plague; how some people died with spitting of blood, obviously the pneumonic form, and how from fear and horror men scarcely dared to carry out the duties of visiting the sick and burying the dead. He ends his chronicle for 1348 by saying "the plague was sore in Kilkenny in Lent, for between March 6 and just beyond Easter, eight preaching friars (i.e., Dominicans) died and in nearly every house there was more than one death for, as a rule, husband, wife, their children, and dependants trod but one way, the way of death."

In an excellent new book on the "Plague in Shakespeare's London," [1] which is really a commentary on Dekker's "Plague Pamphlets," [2] Mr. F. P. Wilson illustrates from contemporary documents the attitude of mind of both the sick and whole during the epidemic of 1625. For the time being it was practically, "Let us eat and drink for to-morrow we die." Many of the clergy and the medical profession, forgetful of their duty, fled to the country, though other

[1] The Plague in Shakespeare's London. By F. P. Wilson. Oxford: Clarendon Press. 1927. Pp. 228. 12s. 6d.
[2] See THE LANCET, 1926, i., 1 99.

do them justice, stayed and worked to the death, ile some, like Mr. Whitacre, survived.

"Mr. Whitacre . . . escaped not only then, but all the ntagion following without any sickness at all; though he ciated at every Funeral and buryed all manner of People, ether they died of the Plague or not. He was given to ak, seldom could preach more than one quarter of an ur at a Time."

Mr. Wilson begins his book by quoting excerpts m various sources as to the theories of the causes he plague, and the various remedies both preventive l curative. It is interesting to note that many of se contained either garlic or onions, both of which well known antiseptics. But as a rule the medical ulty was hopelessly at sea and we cannot wonder Margaret Paston's opinion, not a kindly one, en she wrote to her husband in 1464: "For ddys sake bewar what medesyns ye take of any isyans of London; I shall never trust to them ause of your fader and myn onkyl, whys sowlys l assoyle." The authorities, however, did do ir best to prevent the epidemic spreading, as was wn by the various Plague Orders issued from time time between 1518 and 1665. These dealt with h matters as sanitation, the provision of a state nunicipal medical service (by no means overpaid), angements for burial, segregation of the infected, the establishment of pest-houses for the sick, first of which was in the parish of St. Giles, plegate. Early in his book Mr. Wilson notes the sence of slaughter-houses in the heart of the City mentions that the shambles in the parish of Nicholas within Newgate "were still a menace to lth in 1603," and that in the fourteenth century e putrefied blood of slaughtered beasts was allowed un in the streets." It is true that our ancestors but crude ideas on sanitary matters, but it must remembered that up to 1855, when Smithfield ket was finally closed, much the same conditions ted as in the seventeenth century. The shambles nd Smithfield, Newgate Market, Clare Market, Aldgate High-street were a disgrace to any ilised town and, except the last named, were only e away with on the opening of the Islington ket. On slaughtering-days blood could be seen ning into the gutters in Aldgate High-street at t as late as 1880, and although there was much rovement in recent years the slaughter-houses e only just been closed.

HE ACOUSTICS OF ARTIFICIAL PNEUMOTHORAX.

HE physical conditions under which the coin or sound of Trousseau is heard in the chest are not rately known. In an article which appeared in issue of Oct. 21st Dr. A. I. G. McLaughlin remarked he fact that the sound is better marked when the ra has been thickened or sclerosed by the onset subsequent absorption of a pleural effusion, and it is rarely heard where such effusion has not rred. In a recent publication,[1] Dr. C. Minerbi, S. Mongini, and Dr. E. Benassi deal in a very austive manner with the acoustics of pneumoax. Observations were carried out in 50 young en. In all the cases of complete therapeutic mothorax of recent standing two distinct tones Trousseau's bell sound were invariably found—a er tone corresponding to the extreme points of a eter extending from the interscapular vertebral e to the base of the mediastinum and a lower tone esponding to a line uniting the pleural apex with al margin. The authors also noticed that these sounds were only obtained when the internal sure reached a level between zero and +1 of water manometer—i.e., was not negative. A fact hy of note is that in the first 24 hours after tablishing the pressure in an already complete mothorax the bell sound cannot be produced when the pressure has become positive. The authors ascribe this to a marked "oncopleural reflex," due to the sudden trauma experienced by the pleura. This reflex consisting of a dilatation of the lymphatics and the subpleural parietal veno-capillary network, either by local stimulation or by a reflex caused by compression of the large mediastinal veins, increases the thickness and "succulence" of the pleura, and hence diminishes the firmness of its tissue and the capability of the pleuritic cavity to lend itself to the vibrations of its gaseous contents. It is also worthy of note that the higher tone is not usually found in cases of pneumothorax of many months' duration; this depends, in the authors' opinion, on increased vascularisation and consequent softening of the pleura, and the mechanism is of the same nature as the "oncopleural reflex." It seems, therefore, that the acoustics of pneumothorax are capable of various explanations and more researches are necessary before the subject can be completely and satisfactorily elucidated. The work of the Italian authors is painstaking and includes a bibliography of over 100 references.

[1] rchivio di Patologia e Clinica Medica, vol. vi., fasc. 11,

ENDEMIC TYPHUS IN AUSTRALIA.

IN a recent paper [1] Dr. Frank S. Hone, chief quarantine officer of South Australia, remarks that in three previous communications in 1921 and 1923 he had reported a number of cases resembling typhus fever which had been observed in Adelaide and its suburbs since 1918. During the last four years he has obtained notes of 81 more cases which had been sent to him by more than 25 medical practitioners. The cases in this series presented the same picture as that previously described. The condition was most likely to be mistaken for typhoid fever or measles. In mild cases the patient might not receive medical attention during the initial stage, and only come under observation for a complicating pneumonia in defervescence, when the history and appearance of the skin would suggest the true diagnosis. The prominent points in the clinical history were the headache and the rash. The headache, which was more severe than in typhoid fever, persisted until the rash was well developed. The rash was of the maculo-papular type and petechiæ only appeared in severe cases and at a late stage. The toxæmia varied greatly, being ill-marked in healthy young adults and pronounced in old people and alcoholic subjects. The most frequent complication was hypostatic broncho-pneumonia which was the usual cause of death in the fatal cases. The great majority of the patients recovered. Of the 81 cases only 5 died, a mortality of about 6 per cent.; all the fatalities were men over 60 except a woman, aged 48, suffering from tabes and cystitis. In contrast with European typhus the body louse was invariably absent in these cases. On the other hand, the disease appeared to be closely associated in some way with the prevalence of rats and mice. In its relatively benign nature, absence of lice, and association with rodents as well as in its sporadic character and late appearance of the Weil-Felix reaction, the Australian disease shows a striking resemblance to the tropical typhus of the Federated Malay States and the endemic typhus in the South-Eastern United States to which we drew attention earlier in the year.[2]

THE RELIEF OF STERILITY IN MAN.

OPERATIONS for sterility in man have not met with much success up to the present time. Bilateral epididymitis is recognised as the commonest cause of sterility, and the operations that have been planned to overcome the sequential blockage in the vasa deferentia or the epididymal canal have consisted in various forms of anastomosis and short circuiting. Unfortunately, the lumen of the vas and of the epididymal canal is so small that however carefully an anastomosis is carried out the cicatrisation that

follows the operation undoes its good effect. Results, indeed, have been so disappointing that most English surgeons have abandoned the attempt to treat sterility by operative means. In place of operation the surgeon has tried to meet the difficulty by the withdrawal of spermatozoa from the testis and the use of artificial insemination, but this merely substitutes one hopeless method for another. It is strange that artificial insemination, which gives good results in the stockyard, should be useless in the human being; even when a good supply of semen is available insemination gives no result. There is excellent material here for research. Apparently all the ingredients are present and yet fertilisation is of the very rarest occurrence; one is almost forced to the conclusion that the absence of the psychic element must be called in to explain its negative results. It is, therefore, incumbent upon surgeons to persevere in the improvement of the technique of anastomotic operations in the hope that some day the almost inevitable occlusion of the duct by cicatrisation may be avoided. The operation for sterility, described by Dr. H. C. Rolnick, of Chicago, in the October number of *Surgery, Gynecology and Obstetrics*, has been planned with this idea in view. Instead of carrying out anastomosis between the vas and the epididymal canal, a junction is effected between the vas and the rete testis; the fact that in the latter structure there exist several tubules instead of one increases the chance of success. In order to diminish the risk of sealing up the end of the divided vas a catgut suture is passed through the last inch of the vas, the rete testis, and the testis itself; this is brought out through the skin of the scrotum and tied on its external surface. The suture also acts as an anchor, preventing movements of the testis by the cremasteric muscle and improves the chance of primary union. It is left in seven to ten days and then removed. The whole object of the operation is to reduce to a minimum the amount of scarring round the site of the junction between the vas and the rete testis, and to ensure that during the process of healing the divided portion of the vas shall remain pervious. The operation is too recent to allow of the author publishing results; it seems to have been satisfactory when carried out on dogs.

THE DUST-CELLS OF THE LUNG.

ANYONE who lives in London and looks with the microscope at a bit of the greyish or brownish mucoid sputum which he coughs up in the morning will see a most exquisite example of phagocytosis of dust particles by large clear cells. It is the normal mechanism which does its best to keep our lungs as clear of extraneous matter as may be. Histological sections of the lung of anyone who breathes dirty air show the same picture which is developed to an extreme degree in mitral stenosis, when the remnants of red blood corpuscles which have oozed through the distended capillaries are taken up in great quantities by the similar "heart failure" cells. It used to be thought that these phagocytic cells came from the epithelium lining the alveoli, irritation leading to their proliferation and detachment. But in recent years this origin has been much disputed, and it has been supposed that they were endothelial cells from the lung capillaries or histiocytes from the alveolar walls. A. Policard (Lyons) has combined two views in his hypothesis, that they come from the lining of the alveoli, and that this is mesodermal rather than epithelial. Dr. H. M. Carleton, of Oxford, has recently [1] re-examined the question in a variety of ways—histology, vital staining, tissue culture—and comes to the conclusion that dust cells are indeed derived from the cells lining the alveoli, and that these are epithelial in nature; in other words, he reaffirms the original interpretation. Phagocytosis by epithelial cells is not really so very uncommon, even in mammals; many cancers show an exaggerated degree of it. These epithelial dust cells are, perhaps, chiefly peculiar in their capacity for amœboid movement, for after picking up partic in the alveoli they will penetrate the lymphatics of lung, and travel long distances in these vessels and the bronchial glands.

THE NEW R.A.F. HOSPITAL.

THE building opened at Halton, near Wendov on Monday last will be the principal hospital for Royal Air Force and already has accommodation more than 200 patients. At the opening ceremony Samuel Hoare, the Secretary of State for Air, poin out that there is no intention of duplicating hosp accommodation where military, naval, and c institutions are available for the needs of the Fo Last year more than 1200 R.A.F. cases were admit to naval and military hospitals, which proves, said, a sincere wish to avoid the extravagant po of insisting upon special arrangements being made every man in this branch of the Service. At Halt however, there is no alternative accommodation, although the Air Force station there is the larges the world the hospital has hitherto been housed huts that were erected early in the war and v converted to medical use later. The new build which we describe on page 995, will not only serve local camps, but will also be a centre for all R.A cases for which convenient provision cannot other be made, including those from overseas. The Fo said Sir Samuel Hoare, is rightly proud of its med and nursing service, and the standard of health w it maintains is very high. The most efficient med and surgical assistance is required to meet inevitable strains and risks of life in the air, an the present time, he might have added, there is a need that candidates of the right type should the service. Its attractions from various point view deserve the close attention of men who are committed to any other form of practice.

CHOLECYSTOGRAPHY AND THE LYON TE

CLAIMS for the serviceableness of the duod tube have been put before London medical soci recently [1] by Dr. B. B. Vincent Lyon, of Philadel These claims lend interest to articles appearing i American medical press concerning the relative v of the two main means at our disposal for investig the pathology of the gall-bladder and biliary pass Lyon's test, which consists of the examination o main fractions of bile recovered by duodenal tu after the injection of a solution of magnesium sulp is readily available to every practitioner who ca devote the time and care necessary for its perform Cholecystography, by which the filling and emp of the gall-bladder are observed radiographically the oral or intravenous administration of the he halogenated phenolphthaleins, can never be perfo without expert radiological assistance. It s however, probable that when this latter assista available the method possesses a higher degr accuracy than the Lyon test. Such, at any is the opinion expressed [2] by W. W. Boardman, has made a comparative study of the two metho a series of more than 60 cases at the Stanford M School, San Francisco. Comparing, first, the with the intravenous method of dye administr for the X ray test, he finds a very high marg error when the oral method is employed, more 50 per cent. of his cases having appeared to be p logical by this method, whereas the intrav procedure showed that only 12 per cent. were ac incapable of receiving the dye into the gall-bla These figures are far from agreeing with tho most observers in this country, and suggest tha technique used for oral administration has left thing to be desired. It, however, teaches a that has been learnt here as elsewhere—namely failure to visualise the gall-bladder must be acc with some reserve when the oral method onl been employed. In 11 cases in which both tests

[1] See THE LANCET, Oct. 29th, p. 918.
[2] Amer. Jour. Med. Sci., 1927, clxxiv., 536.

rformed, and in which subsequent operation proved e presence of gall-stones, marked loss of the epithe-m, or thickening of the gall-bladder wall, it was ınd that dark brown "B" bile was obtained in ır cases which had failed to fill during cholecysto-aphy, and which were the site of definite patho-ical change when examined at operation. In inting out this apparent superiority of the X ray st as a means of distinguishing gross disease of e biliary tract, the writer is at pains to remark at the reliability of the Lyon test must inevitably pend to an appreciable extent on the care and perience of the investigator in examining sediment. ith a lesser degree of experience, ordinary observers n hardly expect to obtain results as reliable as ose described by Dr. Lyon himself.

TRIBUTE TO SIR CHARLES MARTIN.

THE appearance of Prof. C. J. Martin's name in e recent list of Birthday Honours was cordially lcomed by the staff of the Lister Institute as a well-served tribute to the high scientific distinction of ir chief during the past 24 years. At a specially ıvened meeting of the staff it was decided that e occasion was a fitting one to present Sir Charles rtin with his portrait as a token of their personal eem and of their appreciation of his services. bscriptions to the portrait were confined to the esent staff and research workers, and to past mbers of the staff during Sir Charles Martin's ectorate. The portrait by Mr. Neville Lewis has en much satisfaction, and its presentation took ce in the library of the institute on Friday last, t. 28th, by Prof. Harden, who presided over a ge gathering of the subscribers. Speaking as one o could recall Dr. Martin's arrival as director of e institute in 1903, Prof. Harden referred in eloquent ms to the scientific and administrative ability ich he had displayed, his versatility and helpful-ss; and he laid stress upon the director's personal alities, saying that his tact had conduced greatly that domestic harmony and camaraderie which l ever been the pride of the Lister Institute. Charles Martin in response testified to the good owship which had always existed among staff and rkers, and thus rendered pleasant the years he l spent among them.

THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

LAST year's industrial dispute seriously delayed e building of the new London School of Hygiene d Tropical Medicine, and the premises are not ely to be opened until the spring of 1929. Mean-ile, the work of the school is steadily growing, and ee divisions are in working order. The Division of dical Zoology embraces a great part of the activities the old Tropical Division; the Division of Bacterio-y and Immunology has been a school of the iversity of London since the beginning of last nth, and has a flourishing course for the new loma of Bacteriology; whilst the Division of idemiology and Vital Statistics has acquired the ne status, and is temporarily established at the tional Institute of Medical Research. The school's rd annual report, which was presented to the vernors on Oct. 31st, refers to the proved advan-es of the lengthened (20 weeks') course in tropical dicine and hygiene, as now given at Endsleigh-dens. The director, Dr. Andrew Balfour, leaves later consideration a proposal to offer shorter rses to medical men who are pressed for time, as the suggestion that brief courses should be anged for laymen who are going to tropical or sub-pical climates. It is felt that the provision of h instruction would be welcomed by business ns and institutions which send their employees road. The interest of the business community is ely to be invoked also when the time comes for sidering the recommendations of the committee appointed by the Minister of Health to report on the best means of securing clinical and pathological facilities in London for the study of tropical medicine. This committee wanted to see an Imperial Hospital of 150 beds set up in London, and pointed out that such a hospital is needed not only for purposes of research and teaching, but also because there is actual suffering at present unrelieved. A possible site is a strip of land in Malet-street, being part of the land in Bloomsbury lately acquired by the University. It would be appropriate if a large part of the £250,000 required for the erection of an Imperial Hospital were to come from commercial people who stand to gain by the opening up of tropical countries.

WE deeply regret to announce the death on Sunday, Oct. 30th, at Forest Edge, Forest Row, Sussex, of Dr. Henry Patrick Cholmeley, at the age of 68. Dr. Cholmeley was for many years assistant editor of THE LANCET, and his death brings real grief to a large number of former colleagues and friends. An obituary notice will appear next week.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXLVIII.

TREATMENT OF BRACHIAL NEURITIS.

CLOSELY comparable to sciatica in the lower extremity, neuritis of the trunks forming the brachial plexus may arise from a large variety of causes, of which chronic goutiness, rheumatic fibrositis, injury, and infectious fevers are the commonest.

Chronic infection from pyorrhœa, antral abscess or other sinus suppuration, chronic intestinal or renal infection, may be the source of an infective peri-neuritis affecting one or more cords of the plexus, more commonly the posterior. Acute brachial neuritis is a most painful affection usually developing gradually during several days from pain around the back of the shoulder and upper arm, soon spreading down to the elbow and wrist and into the back of the hand, and even the finger-tips. When the posterior cord alone is involved then the back of the hand and knuckles is the lowest point for the pain to reach. The intensity of the pain, resembling knives cutting or rats gnawing the flesh, may render sleep impossible without the aid of hypodermic injections of morphia or heroin, and complete rest in bed will be essential with the arm supported on a soft pillow or cushion. Fixation of the limb by strapping or bandaging to the side will not be borne as the patient finds change of posture at intervals an absolute necessity, even though movement for the moment aggravates the pain. Moist heat in the form of an iphlogistine poultices or a paste of kaolin with glycerine and menthol heated and spread on lint, and covered with thick wool, may be kept on for hours at a time; or linseed and mustard poultices, the latter very weak, in the proportion of 1 part to 12 of linseed, may be used and changed every four hours. The linseed poultice should be covered with gauze on the side next the skin, avoiding needless mess. Before applying the actual poultice the skin may be painted with glycerine of belladonna or with warmed lin. A.B.C. made of lin. aconit., lin. bellad., and lin. chlorof. in the proportions of one of aconite to two of belladonna and three of chloroform liniment. Half an ounce of warmed tincture of opium may with advantage be added to the linseed meal in making each poultice.

Ol. gaultheriæ, Bengué's balsam, and similar preparations may be used alternately with the belladonna liniment, though patients are apt to tire of the smell of oil of wintergreen. During the daytime, when the poultices are changed, it is a useful variant to give applications of radiant heat to the neck and shoulder. Sun-ray by the tungsten carbon arc-lamp,

or ultra-violet rays from the cooler mercury-vapour lamp, are also a useful form of treatment. Other forms of electrical treatment may also be employed, such as diathermy and salicyl ionisation. The latter is not very easy to apply to the neck and arm, but may best be given through a moist sponge or thick pads of wetted gamgee tissue. Ionisation sometimes aggravates the pain and should then be given up for radiant heat and poultices.

High-frequency currents in the form of violet sparks, or auto-conduction, are quite useless except as a suggestive treatment, but the positive breeze of a large static machine may act beneficially both directly and indirectly. Faradisation should never be employed, and the same applies to massage in the stage of active neuritis. Not until all signs of active inflammation of the nerve-sheaths in the form of tenderness to light pressure and darting neuralgia have passed away may massage be employed. So limited are the movements of the shoulder-joint permitted by a patient in the first two or three weeks of a severe attack, that adhesions in the joint may form, but though the physician is aware of this he must leave the limb as immobile as the patient will allow, at the same time giving warning that eventually such adhesions may require breaking down under an anæsthetic. In rare cases only do periarticular adhesions form in the wrist and interphalangeal joints.

If marked fixation of a wrist has occurred it is almost invariably evidence that the condition is an active infective arthritis and not neuritis at all. I have more than once seen acute arthritis of the shoulder-joint mistaken for neuritis, while it is a common-place to see chronic adhesions in a shoulder-joint as the result either of subacute rheumatism or of a traumatic synovitis resulting from a slight fall or sudden strain of the joint, diagnosed as "neuritis." The marked fixation of the joint with absence of hyperæsthesia or much local tenderness, and a history of pain limited to the shoulder region, and never extending much below the elbow, will at once distinguish this stage of chronic adhesions in the shoulder-joint from an acute neuritis. This is important to recognise, because the immobilisation necessary in the case of neuritis is the wrong treatment for the former condition, which requires passive movements and massage. In a great many of these cases of fixed shoulder, however, passive movements are useless until the adhesions have been well broken down under an anæsthetic. Gas is sufficient, but the limb must be completely uncovered, and the patient laid flat on a bed, so that the arm can be brought well up over the head. In addition to circumduction movements, it is important not to forget to rotate the joint well also. A point worth attention is the risk of dislocation of the shoulder in the action of bringing the arm up over the head during the anæsthetic. During this movement and before letting the arm down, the operator should press his fist into the axilla, thus keeping the head of the humerus from slipping below the edge of the glenoid cavity. The masseuse who is afterwards to perform the daily passive movements of the joint should be present at the operation, and should manipulate the joint under the anæsthetic to give her complete confidence as to the movements possible. The amount of pain following this slight operation varies; it is a good plan to have a fomentation ready to apply as soon as the anæsthetic is over, and a hypodermic injection of gr. $\frac{1}{4}$ of morphia is generally necessary.

More difficult to treat are the adhesions in the finger-joints which are a sequel in some of the more severe cases of brachial neuritis, accompanied by wasting of the finger-pads and glossiness of the skin. Such adhesions must never be forcibly broken down under an anæsthetic, as this always sets up considerable reaction and swelling with re-forming of the adhesions worse than before. Soaking of the hand in hot soda or brine solutions daily, followed by passive movements of the joints to the limit that can be borne without undue pain, may after many weeks gradually restore the movements of the stiff finger joints, but the process must not be hurried by to forcible treatment or injury will result.

After the pain of an attack of brachial neuritis ha passed off, in four to six weeks or longer, there i certain to be some general emaciation of the lim apart from any local muscular atrophy which ma result from the stress of the neuritis damaging an particular nerve-trunk. Massage of the limb may no safely be employed and faradisation best given wit the slower interruptions of the Bristow coil, or wit wave faradism, produced either by rhythmically slidin the secondary to and fro over the primary, or by passin the current through a pointed electrode dipping i and out of a narrow tube containing water, by th action of a motor or metronome.

By these means the recovery of the general wastin will be hastened. When the stress of the inflammatic damages certain nerve-trunks to the extent of causin degeneration of the nerve-fibres, local muscular atroph will be observed corresponding to the nerve-supp —e.g., atrophy of the serratus magnus when the lor thoracic nerve is involved, or of the deltoid in th case of the circumflex. When this degree of dama is done, electrical tests will show the presence reaction of degeneration—that is to say, the musc will not respond to the faradic current, but will sho sluggish contractions to galvanism, with perha stronger reactions to the closure of the current the anode. Faradism will then be of less use in th treatment of the wasted muscle than reversals interruptions of galvanic current.

A frequent form of neuritic pain about the shoulde joint that is generally diagnosed as neuritis is real a neuro-fibrositis, due to a subacute or chron fibrositis affecting the fascial planes and intermuscul septa at the base of the neck and shoulder. T ætiology of this condition is very similar to th of the more general brachial neuritis affecting t main nerve-trunks, the difference consisting in t situation of the fibrositis, either surrounding or a distance from the main nerves. The pain in th form of neuro-fibrositis mainly affects the should and base of the neck and does not spread down t arm below the area of the deltoid, except in a fe cases which commence as a diffuse fibrositis a spread to the sheaths of the main nerves, when t pains will extend further down the arm, even to t finger-tips.

Local radiant heat, sun-ray lamp or diatherm ionisation, and poultices will be of service as in t general brachial neuritis, but the pain is less seve and does not cause sleepless nights, requiring the u of morphia or heroin. Careful examination f sources of sepsis of dental or sinus origin must be ma and dealt with appropriately. Alcohol in all for should be forbidden in the acute stages of neurit though total abstinence is less necessary in neu fibrositis. Diet is of less importance than is oft stated, but the meals should be small in persons ov the age of 50. Internally, aspirin or salicylates, m purgation, and sometimes atophan should be tried.

Occasionally these cases become chronic, w persistence of neuralgic pain, especially on certa movements, and a few points may be found especia tender to pressure, particularly around the verteb border of the scapula or above the suprascapular fos These tender points should be carefully located a marked with a dermatograph pencil, and drama cures may occasionally be wrought by injecting th with a fine needle, using first two or three drops 2 per cent. novocaine solution and after waiting th or four minutes injecting 5 minims of 90 per ce alcohol. Great care must be taken when performi these alcohol piqûres over an intercostal space ne to pass the needle through the pleura. To avo this accident search should always be made w the point of the needle for the rib, this indicating t depth that is safe.

WILFRED HARRIS, M.D. Camb., F.R.C.P. Lond.
Senior Physician to St. Mary's Hospital and Hospital fo Epilepsy and Paralysis, Maida Vale.

Special Articles.

THE MINISTRY OF HEALTH:
ANNUAL REPORT.

THE report of the Ministry of Health for the year ding March 31st last contains an interesting summary the work of the department with respect to public alth. Eight years have now elapsed since the nistry was first formed, and advantage has been ken of the present opportunity of summarising its tivities as regards development and organisation. n outline of the volume should stimulate readers acquire it.[1]

International Work.

In the first place, the report deals with international alth work, the Convenant of the League of Nations ving placed on the constituent members certain ties relating to public health which were of an ernational nature. The permanent health organisan of the League has been concerned with the lection and circulation of particulars of the evalence of epidemic disease, and the provision of sistance to other nations in coping with formidable idemics, together with such work as the interchange visits between public health officers working in ferent countries, and the collection of statistics ating to cancer and tuberculosis. In connexion erewith an International Sanitary Conference was d in Paris from May 10th to June 21st, last year, e object being to revise and bring up to date the rk of the International Sanitary Conference of 1912. fewer than 70 countries participated in the iberations, and the conclusions of the Conference l be published separately, but, in brief, it may be ted that the Convention establishes the procedure ich should be followed on sea and land frontiers h regard to the importation of cholera, plague, low fever, small-pox, and typhus. The International alth Office in Paris will act as a clearing house of ormation as regards these diseases. A Conference s also held with regard to the prevalence of epidemic eases in the islands in the Pacific, and a unanimous ort contains recommendations as to the methods be employed in supplying information as to the idence and spread of those diseases in those areas.

Variety of Interests.

nstances may be given of the great variety of portant subjects which come within the scope of Ministry's activities. The Ministry have taken active part in connexion with committees which ve sat during the year under review with regard certain comparative aspects of child welfare, cancer, laria, and vaccine lymph. Inquiries were also de into the sanitary conditions in representative as of Northern Europe by 16 port medical officers various nations, in which four English ports were luded. Reference is made in the report to the ommendations of the Royal Commission on lunacy l mental disorder which was presented to Parliant last year. This report is still under the seration of the Ministry. There were 57,313 nurses istered under the Nurses Registration Act (9 and 10 . V. c. 94). In connexion with this it may be interest to note that during the year in question 2 nurses trained in Poor-law institutions sat for preliminary examination of the General Nursing ncil, of whom 1058 passed; and 1082 sat for the al, of whom 758 passed. The report remarks t the important contribution made by the Poor- service to the recruitment of the nursing profession s been secured for the future by the recognition of ny Poor-law infirmaries by the General Nursing ncil as training schools for general nursing.

[1] London: H.M. Stationery Office, or through any Bookseller, 7. 5s.

Notifiable Diseases.

From the table of the principal notifiable diseases it appears that there were 51,069 cases of diphtheria (including membranous croup), which was about 2500 over that for the previous year. There was a very marked decrease in the numbers of scarlet fever cases, the numbers being 81,672 as against 91,362 for the previous year, but small-pox cases increased by nearly 5000, but of which only 11 were fatal. The chief centre of infection from small-pox was in the County of Durham, which had 6645 cases. The report states that—

"the efforts of the local authorities and of their officers to combat the disease have been hindered by the indifference with which the disease is regarded by many persons, and by the consequent neglect of vaccination and of the most rudimentary precautions in the invaded areas . . . . It has been amply established that vaccination and revaccination afford a sure protection against this mild type of small-pox as well as against the more virulent type. On reference to the detailed figures in the report of the chief medical officer for 1926, it is shown that during the year no vaccinated person under the age of 13 years contracted the disease, and there was no instance of a person attacked by small-pox who had been vaccinated during the past eight years."

During the year 1925 only 44·2 per cent. of the children born were vaccinated. Although there was a large increase in the cases of small-pox during that particular year, yet the number of children vaccinated was lower than in the two previous years, when the number of small-pox cases was also lower. From the report it does not seem that local authorities coöperate as they might in cases of epidemics of small-pox. In one district there were some small-pox hospitals very much overcrowded, whilst other small-pox hospitals had vacant accommodation. To cope with this situation the Minister issued regulations under the Public Health (Prevention and Treatment of Disease) Act, 1913, by which regulations the county council concerned were enabled to coördinate the hospital resources of the county. A circular letter was addressed by the Minister to boards of guardians, drawing their attention to the need for strict compliance with the regulations, to prevent unrecognised cases of small-pox entering institutions and so spread infection.

Tuberculosis.

With regard to tuberculosis, the number of beds in residential institutions approved by the Minister has increased during the period under review by 779, the total being 22,202, of which 14,165 were provided by local authorities. The number of areas which contain out-patient clinics for tuberculous and other cripples is at present very few, but the Minister states that there is increasing evidence that—

"the local authorities generally realise the importance of making arrangements which will provide for the in-patient treatment of cripples at a properly equipped orthopædic hospital, and for their care and after-treatment at clinics established in connexion with the hospital and supervised by its medical staff."

Local authorities were advised by the Ministry that pretuberculous children should be dealt with by the local education authority in open-air schools and not in sanatoria. The report adds that Mr. Spahlinger's method of treatment for tuberculosis cannot be properly investigated here under present conditions. Inquiries with regard to Prof. Calmette's methods of inoculation are still proceeding, but it must be some years before a definite opinion can be expressed as to its efficacy. Tests are being made in Scotland of the method of treating this disease devised by the late Prof. Ruppel, but up to the date of the report the results of the tests were not known. The number of cases on the Register of Infections kept by medical officers of health was 358,133, of whom 165,987 were females. The number of deaths from tuberculosis has dropped from 54,295 in 1915 to 37,525 in 1926. The number of deaths from pulmonary tuberculosis has decreased more than 25 per cent. during the past 12 years and the deaths from non-pulmonary

tuberculosis have decreased by 45 per cent. during the same period.

Medical Benefit under the National Insurance Acts.

The total cost of medical benefit to the insured population was approximately £7,857,000, of which about £5,887,000 was paid to practitioners in respect of treatment, the balance being allocated to drugs and appliances. £200,000 was distributed to rural practitioners for mileage payments. (The insured population of England entitled to medical benefit was about 13,200,000.) £1000 was deducted from the remuneration of 77 medical men in 1926 as against £1549 to 105 practitioners in 1925, which, in turn, was a decrease of £504 and 29 respectively during the year 1924. Of the 77 cases above referred to only 16 cases were dealt with which involved allegations of failure or refusal to visit, unsatisfactory treatment, &c., and the department rightly says that this indicates that a high standard of treatment has been secured. Of the remaining 61 cases, 15 were in respect of irregular certification, 5 cases of fee charging, and 21 of failure to keep proper records. The highest amount withheld was £60 which was for failure to keep proper medical records. The other sums varied from £2 2*s.* to £50. There were 314,710 persons referred to the regional medical officers for report, this representing an increase of 70 per cent. on the figures for 1925. Of this number over 75,000 "declared off" the funds prior to examination and nearly 63,000 failed to attend. Of the remaining number (about 175,000), 30 per cent. were found to be incapable of work.

New M.O.H.'s.

During the year 70 new appointments of medical officers of health were sanctioned by the Minister. In 30 cases the officer appointed will devote his whole time to the duties, and by the end of the year 349 (out of 1231) medical officers of health in England were full-time officers.

MEDICINE AND THE LAW.

Doctors' Accounts: Liability to Render Details.

THE county court judge at Newcastle is reported to have stated in a recent case that a doctor's patients are entitled to detailed accounts and that in this respect a doctor is in no better position than any tradesman. This is no doubt the strict law, but the learned judge's dictum need not be interpreted as meaning that a medical practitioner must in future render all his accounts with the detailed itemisation of a grocer's bill. The contract between practitioner and patient is that the patient will pay the reasonable charges for services rendered. Naturally the patient, if he desires to go into details, is entitled to know what are the services for which charge is made and what is the charge for each service, so that he may form his own conclusion whether the charges are reasonable or not, and may contest them if he considers them excessive. The remarkable feature of the contractual relations between the medical profession and its patients is that, although the services rendered are often difficult to assess in pounds, shillings, and pence, there is rarely any agreement in advance as to the exact amount to be charged and yet there is seldom any challenge by the patient of the doctor's bill which, perhaps, does not reach him till long after the services have been rendered. The practitioner must always be prepared to justify his charges by furnishing details, but the patient will probably appreciate the fact that a lump sum account is often a smaller amount than the total of a catalogue of particular items from which no detail is omitted.

Alleged Food Poisoning in Restaurant.

The recent action of Richards *v.* Appenrodt Ltd., tried before Mr. Justice Horridge and a special jury, was a claim by a plaintiff described as a beauty specialist for damages for personal injuries alleged to be caused by food poisoning due to her having eaten a liver sausage sandwich at a Piccadilly restaura belonging to the defendant company. As is usu in these cases, the plaintiff's counsel was obliged admit the impossibility of direct proof that the poiso ing was due to any particular portion of food; t court was asked to infer from the evidence that t particular food caused the poisoning. Medical eviden was called in support of this inference, though it w admitted in cross examination that all the sympto might not have been caused by food poisoning and th the period of incubation of bacilli varied from a f hours to four days, so that it was conceivable that t poisoning might have developed as a result of fo eaten earlier. The manager of the defendant compa said that on the average 20 lb. to 30 lb. of sausa were delivered every morning at these premis Most of this material would be sold the same da If any remained unsold, it was placed in an ice-s downstairs if the weather was unfavourable; if weather was dry, it was left on dishes in the sh It was also stated that any sausage sandwic remaining over at the end of the day were given aw and that the company had a contract with a firm insect killers for keeping the premises free of verm a representative of this firm visiting the premises o a week. The sanitary inspector for the borough Holborn and the manufacturer who supplied sausages gave evidence that the place of manufact was perfectly clean. The jury found for the defend company.

Euthanasia.

Mr. Justice Branson, at the recent Chester Assi used some remarkable words in drawing the attent of the grand jury to the case of a father who, accord to the depositions, had taken the life of his li daughter to put an end to her sufferings from incurable disease. "It is a matter which gives food thought when one comes to consider that, had poor child been an animal instead of a human be so far from there being anything blameworthy in man's action in putting an end to its suffering, would actually have been liable to punishment if had not done so." The facts of the case were of t pathetic kind to which many medical practitio could find parallels in their own experience. man's wife died early this year, suffering from tu culosis and curvature of the spine. She left children. One of these—a little girl 4 years of a also contracted tuberculosis and, early in J developed gangrene in the face after an attac measles. The father nursed the child with dev care. The doctor was of opinion that she could live long. One morning last July, after sitting u night with the child, the father went to his mothe law's house and told her he had drowned the l girl, as he could not bear to see her suffering any m He then surrendered to the police, informing t that he had put the girl in a bath where the p found her lying face downwards in nine inche water. Medical witnesses said that the child's d was expected from the nature of her disease, and she was in such a state that shock would have ca death if an attempt had been made to move h hospital. The doctor, replying to counsel for defence, conceded that it was conceivable that child could have died from shock consequent on being lifted out of her cot. Perhaps on the bas this answer the jury mercifully found itself abl return a verdict of "Not guilty."

A WARWICKSHIRE CONVALESCENT HOSPITA Keresley Hall, a "black and white" house a few miles Coventry, has been bought, with 10 acres, by the Coventr Warwickshire Hospital as a clearing-house for convales

MANCHESTER AND SALFORD MEDICAL CHAR FUND.—At the annual meting of this Fund it was s that for the year ending June 30th last the ordinary i had amounted to £33,055, as compared with £22,254 in From the Alexandra Day effort £3870 had been rece whilst the university students on Shrove Tuesday collected £12,061. The expenses of the fund amount about 6 per cent. of the receipts.

Public Health Services.

OMEN AND PUBLIC HEALTH APPOINTMENTS.

HE Medical Women's Federation, having noted t a large proportion of the underpaid public health ointments advertiscd by local authorities are g accepted by women, has issued the following ice :—

omen who may be tempted to accept these black-listed intments are asked to remember the following facts :—

That the whole position of women in the medical ession depends on their complete loyalty to professional dards of conduct and policy. They would never have admitted to professional organisations nor accepted olleagues in any sense if it had been anticipated that would attempt to undercut their male competitors. ing is more calculated to introduce an element of rd into the relations of men and women in the profession a spread of this practice.

That the salaries offered would be far lower than they now but for the determined stand made in pre-war . The present position is not a new one. Medical en ever since their admission to the profession have to make precisely the same sacrifices for principle as now demanded. With the inauguration of the School cal Service in 1908, and later when maternity and welfare posts were created, persistent efforts were e by local authorities to pay their assistant medical rs below the British Medical Association minimum, to secure women at a lower rate than men. With rare ptions the efforts were a failure, and " black-legging " so uncommon that until the close of the war, comtively few authorities wasted time in advertising posts w the agreed minimum.

That the salary scale fixed by the British Medical ciation and the Society of Medical Officers of Health ne too high in relation to the enormous expense of cal education and the heavy cost of maintaining a ehold. Young men and women with few responsiles should do nothing to make life impossible for the y of both sexes who have heavier obligations.

That lowered pay invariably implies lowered status and ige. Holders of appointments which have been banned iably find themselves cut off from professional advance- and stultified in all their work. The woman who ps herself as belonging to an inferior grade of doctor ot complain if she is taken at her own valuation.

That in regard to salaries, the minimum always tends come a maximum, and once the agreed scale is aband and the professional ranks are broken, the lowest ies will tend to be adopted by other authorities making appointments. Authorities wishing to be economical d proceed still further, and the scale all over the country d be rapidly depressed.

That attempts to evade the scale and split the ranks he profession by offering a man's post at the agreed and a woman's at slightly below are particularly to be ecated. Where the rule of " equal pay for equal work " plated, there is no limit to the extent to which women be exploited and sweated. Medical women in the c health service have often been faced with the danger rise for male employees only, which could only be ed by appealing to an inviolable rule.

That a woman who has betrayed her professional ren, past, present, and to come, cannot expect the ort of her colleagues or of professional organisations y time in her career.

he leaflet is being distributed to all newly qualified ical women and to applicants for underpaid posts.

FECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 22ND, 1927.

otifications.—The following cases of infectious ase were notified during the week :—Small-pox, 0 (last week 124) ; scarlet fever, 2450 ; diphtheria, 43 ; enteric fever, 71 ; pneumonia, 975 ; puerperal r, 37 ; puerperal pyrexia, 93 ; cerebro-spinal r, 6 ; acute poliomyelitis, 30 ; acute poliophalitis, 3 ; encephalitis lethargica, 30 ; dysentery, ophthalmia neonatorum, 128. There was no case holera, plague, or typhus fever notified during the k.

the 200 cases of small-pox, 14 were reported from the ty of Derby (Alfreton 10, Ripley 3, Belper 1), 45 from nam (Gateshead and South Shields 11 each, the remainder scattered over many urban and rural districts), 7 from Gloucester (Bristol 6, Warmley R.D. 1), 1 from Lancaster (Preston R.D.), 4 from Northumberland, 8 from Nottingham (1 from the county borough, the others scattered over the county), 5 from Warwick (Coventry R.D.), 8 from Yorks, North Riding (Middlesbrough 7, Eston 1), 34 from Yorks, West Riding (Doncaster 2, Leeds 6, Sheffield 3, the others from nine districts), 5 from Brecknock (Brynmawr), 24 from Glamorgan (Aberdare 10, Gelligaer 3, Mountain Ash 2, Pontypridd 9), 45 from Monmouth (34 of these from Ebbw Vale).

*Deaths.**—In the aggregate of great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 20 (1) from measles, 2 (0) from scarlet fever, 10 (0) from whooping-cough, 39 (8) from diphtheria, 65 (13) from diarrhœa and enteritis under two years, and 63 (15) from influenza. The figures in parentheses are those for London itself. The number of stillbirths registered during the week was 260 in the great towns, including 45 in London.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1926 statistics of eight London boroughs in different parts of the metropolitan area :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Diarrhœa, &c., under 2 years.	Infant mortality.	Maternal mortality from childbirth.
Kensington .. (180,000)	15·1	12·8	0·89	1·91	2·4	2·1	13·6	60	3·3
St. Marylebone .. (105,800)	12·7	12·8	1·03	1·60	3·0	1·3	11·8	82	8·8
Hampstead .. (87,530)	12·3	10·6	0·64	1·54	1·6	1·6	5·5	60	2·8
Hackney .. .. (228,500)	17·2	10·8	0·88	1·41	2·1	1·4	17·0	59	4·8
Holborn .. .. (43,200)	12·4	12·1	0·81	1·46	2·7	1·3	22·4	90	3·7
Poplar .. .. (169,000)	21·6	11·4	0·96	1·27	2·5	1·3	17·2	70	3·5
Battersea .. (171,900)	17·3	11·4	0·96	1·53	1·8	2·0	9·4	62	3·4
Deptford .. .. (115,700)	18·2	11·3	0·90	1·37	1·9	1·6	9·0	56	4·7

The neonatal mortality-rates show a wide variation—viz., Kensington 18, St. Marylebone 28, Hampstead 33, Hackney 20, Holborn 41, Poplar 25, Battersea 27, and Deptford 23.

Kensington.

Dr. James Fenton points out that one of the satisfactory features in the drop of the infant mortality-rate from 78 in 1925 to 60 in 1926 is the decline in the number of deaths in the first month of life, the neonatal mortality-rate being only 18. He attributes this result to the concentration of effort on antenatal work in recent years. Antenatal work is now conducted at nine centres, including the clinic at the Queen Charlotte's Hospital Nurses' Home. More than 50 per cent of the working class mothers receive antenatal advice. During the last five years there has been only one maternal death following confinement amongst the women who have attended antenatal clinics in the borough during pregnancy, whereas there have been 57 deaths amongst those women who have not attended antenatal clinics. The borough has a good midwifery service. The council has a maternity home with ten beds and the guardians also have a ten-bed ward for confinements. The Queen Charlotte's nurses' home through its staff conducted 822 Kensington confinements. The antenatal work of this home is conducted by the medical staff of the hospital. The council maternity home was opened in 1924 in the grounds of St. Mary Abbot's Hospital, and the council pay to the guardians 5*s.* per day for each maternity case admitted, and

* See also p 1002.

the cost of additional nursing if required. During 1926 the council paid £853 in respect of 123 confinements and recovered £336 by patients' payments. For dealing with puerperal pyrexia, Dr. Remington Hobbs, medical superintendent of St. Mary Abbot's Hospital, has been appointed to act as consultant to the medical practitioners in Kensington, and arrangements have been made for the admission of cases of puerperal pyrexia into his hospital. Of 11 notified pyrexia cases 9 were removed to hospital and the only one who developed puerperal fever made a good recovery.

During the year a conference was held with various interested organisations to consider steps for reducing the damage done by rheumatic fever. As a result a scheme was formulated for the notification of rheumatic children under 16 years of age and for the establishment of a supervisory clinic, and this scheme has now become an accomplished fact.

The council has installed apparatus for the constant aeration and filtration of the water in all the four swimming-baths. The plant selected was that of the Pulsometer Engineering Co. and the results have been very satisfactory. A scheme for the prevention and early treatment of zymotic enteritis has now been in operation for three years under the superintendence of Dr. Ronald Carter. Full particulars are given and the results are claimed to be very effective. The nursing staff at St. Mary Abbot's Hospital are being immunised against diphtheria and the tuberculosis wards at this hospital are now linked up with the council's dispensary scheme. Dr. Fenton gives an encouraging account of housing conditions. The condition of the 2091 mews dwellings has been much improved. "Furnished houses," the most undesirable form of housing, have been gradually reduced from 187 in 1912 to 53 in 1926. For the purpose of the new by-laws the definition of "houses let-in-lodgings" has been altered by the exclusion of houses in which the tenant lives and in which not more than two additional persons or one family lodge. The difficulty in finding housing accommodation is becoming less and it is now possible to deal more actively with cases of overcrowding discovered.

St. Marylebone.

Dr. Chas. Porter cites as one of the chief events of the year the "representation" to the appropriate authorities that the Carlisle-street area must be regarded as an unhealthy one. The area covers about 16 acres and includes 533 premises and an approximate population of 5000. Negotiations with regard to the improvement scheme are in progress with the Ministry and the London County Council. There are about 300 premises in which meals are provided or food is sold ready cooked or is prepared for sale. On more than one occasion the St. Marylebone Council has pressed the Ministry and the London County Council to institute legislation for the registration of such premises, but no action has yet been taken by either of the authorities mentioned. Sterilised milk is permitted to be sold in unopened bottles without registration. Two vendors were successfully prosecuted during the year for selling this milk other than in the unopened bottle. The public analyst, Mr. J. F. F. Rowland, draws attention to the need for a cream standard. The ordinary cream samples examined during 1926 had an average fat percentage of 54·7, while the average fat in the tinned cream samples was only 28·87. Some of the tinned creams, he says, can only be truthfully termed enriched milks.

Hampstead.

Dr. Frank E. Scrase reports that it is the duty of the health visitors to inquire into and report upon all maternal deaths, stillbirths, deaths of children under 2 years of age, and cases of puerperal sepsis, and that a special subcommittee, including the three medical members of the health committee, Councillor T. Hancock Nunn, and Dr. Mary B. Douie (coöpted) has been appointed to go into the details of each case reported upon. During 1926 this subcommittee investigated 75 infant deaths, 39 stillbirths, 3 maternal deaths, and 10 cases of puerperal fever and pyrex Amongst other results it was found that 20 of t 39 stillbirths were due to difficulties in labour a were cases in which the services of the consulti obstetricians provided by the council might ha been advantageously utilised. The facilities require under the new regulations for puerperal pyrexia, ha already been in operation for some time in Hampstea Arrangements are also in force with the two nursi associations by which skilled maternity nursing c be obtained for any case in the borough. At t end of the year a scheme for the provision of artific light treatment for children attending the centr began to operate. The antenatal clinics in Hampste have always been municipal undertakings. Duri 1926, 308 expectant mothers attended, the total birt in the borough being 1077. The public analy Mr. H. E. Cox, draws attention to the fact th soft cheeses prepared from milk are not infrequen sold as cream cheeses. He also presses for a standa for cream. Of four samples of ice-cream examin two were merely frozen custard powder.

Hackney.

Dr. G. H. Dart gives the particulars of the fi year's work of the municipal centre in Lower Clapt road, which includes antenatal, child welfare, lig and dental clinics. Dr. Dorothy Gere successfu treated 190 cases at the light clinic, the length treatment varying from four weeks in skin disea to nine months in rickets. "Dramatic results" w obtained in impetigo and some cases of eczema a acne. Dr. Gere also claims to have obtained g results from the use of radiated dried milk in rick marasmus, and other conditions. The council h appointed Lady Barrett to act as consultant accordance with the puerperal pyrexia regulatio and have made arrangements with the Camberv research laboratories for the bacteriological w required. Skilled nursing and hospital treatm were already available. The number of expect mothers attending the four antenatal centres was 9 the total births being 3949. "The River Lea remained, during the past year, in the usual offens condition." Severe floodings occurred in Hack as the result of a storm on Sept. 1st, but the Lon County Council are said to be contemplating impro ments to their sewerage system which will prev future floodings.

Holborn.

Dr. C. W. Hutt says that the scavenging arra ments have been improved by the introductio motor vehicles. The collection of house refuse in main streets is now completed by 9 A.M., and mos the large old ashpits have been replaced by b The removal is done by a contractor. The refus first removed to the contractor's depôt at Vauxh where it is sorted and the useful portion salved. remainder is removed to dumps on brickfields Sittingbourne, where some of it is used for br making. The nearest house is one mile away from dumps and no nuisance is said to be created. Holborn Council are taking part in an investiga into the composition of house and trade refuse in metropolitan area, instigated by the Ministry Health. Five-ton samples of refuse have been ta at different seasons and from different classes property, and the samples divided according to fineness of the ashes and the other material suc vegetable matter, paper, metal, rags, glass, and b all weighed up and classified. Systematic efforts the suppression of rats have been maintained thro out the year. Dr. Hutt reports adversely with re to the proposals in the Factories' Bill of 1926. He tends that the proposal to transfer sanitary contr factories to the Home Office is undesirable, and dual control, extra expenditure, and no greater e ency would be the result. The Holborn Council passed a resolution disapproving of the new propo

Out of 25 samples of milk examined three found to contain tubercle bacilli. But little sati tion resulted from following up the cases, as modern practice of mixing milk at large cream

rendered it impossible to say from which farm the infected milk came. Efforts are being made to improve the conditions under which ice-cream is made in the "Italian colony" of Holborn.

The immunisation of children against diphtheria is being prosecuted energetically in Holborn. During the last five years about 1000 children have been Schick tested, of whom 752 were positive. Five hundred and ninety-one have been immunised, and the reaction after the injection of the toxin antitoxin and toxoid antitoxin has been in practically every case negligible. Dr. Hutt urges the importance of having the immunisation carried out as soon after the age of 6 months as possible, as more than half the deaths from diphtheria in London occur before the school age.

Poplar.

Dr. Frederick W. Alexander, in his thirty-fourth and final report, wishes the borough "may have the highest birth-rate and the lowest death-rate in the kingdom and an infantile mortality so negligible that there will be no necessity in future for a heading in future annual reports." A new and commodious welfare clinic was opened in North Poplar in January at a cost of about £3000. The maternity beds provided by the guardians are insufficient to meet the needs, and the establishment of a new joint maternity home by the council and guardians is under consideration. An additional health visitor has been appointed. The maternity and child welfare work is divided between the council and the Royal College of St. Katharine. Dr. E. M. Layman reports good results at the two municipal artificial light clinics. Illustrative charts are given and a full description of the technique employed. The report as to the results obtained at the light clinic of St. Katharine's is not so enthusiastic. Dr. A. G. Hamilton, who is in charge, finds that he obtains better results in the summer by exposing children to direct sunlight out of doors. He pictures the artificial sunlight room of the future as "a large, well-ventilated, well-warmed room, flooded with light from multiple sources, where the children can play in safety with nothing but their eyes shielded from the rays. The present method of short exposures, with children sitting or lying inert, has its obvious disadvantages." Prints of the plans of the observation wards, under construction at Wellington-road, are included in the report. The building contains on the ground floor two five-cot wards and an isolation ward, accommodation for a dental clinic, light clinic, milk laboratory, and a flat roof for open-air treatment, with the necessary accommodation for the nursing and domestic staff.

There were 43 notifications of ophthalmia neonatorum; the last case of impaired vision from this cause occurred in 1922. The visiting of cases of zymotic enteritis is most unsatisfactory owing to the uncertainty of the notifications. In 15 cases death occurred before the notification was received. The council resolved to supply Grade A (T.T.) milk for their free milk scheme from Jan. 1st, but in September it was reported that 15 out of 43 samples of this designated milk had proved unsatisfactory, and it was proposed to discontinue its use. Ultimately it was decided to reconsider the matter in April, 1927. The chief difficulties of the tuberculosis scheme are the shortage of adequate housing accommodation and the almost complete lack of work for tuberculous patients capable of being employed under special conditions.

Rebuilding is now proceeding in two unhealthy areas, in one case by the Poplar Council and in the other by the County Council. Four samples of margarine were found to be adulterated with mineral oil, varying in amount from 10 to 15 per cent. The analyst, Mr. A. E. Parkes, reports that many vendors sell as "pure cocoa" a compound containing added alkali. He thinks that such cocoa powder should have some special designation.

Battersea.

Dr. G. Quin Lennane says the outstanding feature of the year's work has been the development of antenatal work in connexion with the midwifery services. There are five municipal infant welfare centres and three voluntary ones. The antenatal cases are referred from the voluntary centres to the municipal, except in the case of one, which has a fortnightly antenatal clinic. The antenatal work is under the careful direction of Dr. Alice Bloomfield. The central clinic is at the borough maternity hospital and there are three branch clinics. The total patients attending numbered 1208. The births in the borough were 2969. It is an inflexible rule that every expectant mother, who applies for admission to the maternity hospital or for the services of the district midwife, should attend one of the antenatal clinics. The maternity hospital, with accommodation for 30 patients, admitted 625 cases, 14 of which came in for antenatal treatment. Of the cases confined 570 were delivered by midwives and 41 by doctors. In ten of the cases the consultant obstetrician, Dr. J. S. Fairbairn, was called in. Dr. Bloomfield reports that the cases attend at an earlier stage of pregnancy than heretofore. Thus 453 attended before the sixth month, 356 between the sixth and eighth months, and only 74 after the eighth month. Out of 906 new patients, only five cases of breech presentation escaped diagnosis; 17 breech cases were admitted to the hospital for external version under anæsthesia, and in seven of these version was successful, while in the remaining ten labour resulted in a living child in all but one case. A special V.D. clinic is held at the maternity hospital. Of the patients tested, 3·5 per cent. had a positive Wassermann in 1924, 2·1 per cent. in 1925, and 1·5 per cent. in 1926, the numbers tested in these years being 517, 653, and 658 respectively. Of the ten who gave a positive reaction in 1926, nine treated at the antenatal clinic had healthy babies. Six of these babies had a negative Wassermann and the other three had not been brought up for testing at the end of the year. The previous results of the pregnancies of these nine women are interesting. Thus 25 pregnancies resulted in 7 miscarriages, 2 stillbirths, 5 children who are already dead, and only 11 now living. Complete arrangements have been made to meet the puerperal fever regulations, and Mr. A. H. Richardson, of St. Thomas's Hospital, has been appointed consultant.

Considerable progress has been made with the Plough-road area improvement scheme, and photographs are given of the houses prior to demolition and the new tenements which have replaced them. The serious overcrowding in some of the wards has not been to any adequate extent abated owing to the lack of housing accommodation at low rentals.

Deptford.

Dr. Charles S. Thomson explains in popular language the rationale of diphtheria immunisation schemes. He shows how unsatisfactorily notification of pneumonia is working. There were 185 notifications and 108 deaths. He is not sanguine that the services of the consultant will be much utilised in the case of puerperal fever. He puts forward as some of the pressing needs of Deptford: a mothers' home for difficult breast-feeding cases; a hostel for babies when the mothers are forced to go into hospital; toddlers' playgrounds, as in Edinburgh; and a development of the educational side of the maternity and child welfare centres with sewing classes, lectures, and so on. New cases attending the antenatal clinics numbered 499 and the births in the year 2108. A great deal of attention has been given to the conditions under which people work in the workshops and factories in the borough, and a number of improvements have been inaugurated as the result of the visits paid. It reads as somewhat anomalous that previous to the inspections no washing facilities were provided at the soap works. There appears to be little prospect of any tangible amelioration of the widespread overcrowding. Some applicants have been fortunate in obtaining London County Council houses at Downham or Becontree, but the main desideratum is housing accommodation near at hand at an economic rent. The "representation" made in 1920 involved some 24 streets and 811 houses but

no action has yet been taken. A beginning has, however, been made with the Watergate-street area. The tuberculosis care committee has done useful work; a few children from infected homes have been boarded out under the London County Council scheme. At the light clinic, which is held in the basement of the Town Hall until the new Deptford health centre is built in Harton-street, there were 185 patients under treatment at the end of the year.

The Services.

INTERNATIONAL CONGRESS OF AIR NAVIGATION.

AT the recent Air Congress in Rome, presided over by Principe Amedeo Di Savoia-Aosta, the medical section was chiefly concerned in confirming the ordinary routine of its reports. Air Vice-marshall Munro was, unfortunately, unable to be present, but the proceedings were purely formal, the rapporteur, Signor Garsaux, reading out a subcommission's recommendations. Those of the most practical interest concerned some relaxation in the standards of fitness for pilots who had given previous proof of flying ability, while alterations were suggested in the period after which they had to come up for re-examination.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs.: H. W. Fitzroy-Williams to *Egmont*; P. M. Rivaz to *Barham*; and W. H. Edgar to *Vivid*, for *Rodney* (on commg.).

Surg. Lts.: S. G. Weldon to *Revenge*, on transfer; J. L. Malone to *Nelson*, on transfer; V. G. Horan to *Vivid*, for *Rodney* (on commg.); G. Rorison to *Barham*; and J. J. Keevil to *Warspite* (both on transfer).

ROYAL ARMY MEDICAL CORPS.

Maj. R. G. S. Gregg retires on ret. pay, and is granted the rank of Lt.-Col.

Maj. J. M. Pinkerton to be Temp. Capt., and temporarily relinquishes the rank of Maj.

Capt. D. J. MacDougall to be Maj. (Prov.).

S. M. Burrows to be Temp. Lt.

Lt. (on prob.) P. G. Bentlif, from the secd. list, is restd. to the estabt.

Temp. Lt. J. W. Dowzer relinquishes his commn.

ARMY DENTAL CORPS.

Capt. A. B. Austin to be Maj.

Capt. O. G. E. Simpson retires, receiving a gratuity.

ARMY RESERVE OF OFFICERS.

Maj.-Gen. J. J. Gerrard, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

ROYAL AIR FORCE.

Flying Officers G. M. Anderson and B. L. Edwards are promoted to Flight Lts.

INDIAN MEDICAL SERVICE.

Lt.-Cols. J. D. Graham and M. MacKelvie to be Cols.

Capt. Sukumar Nag to be Maj.

Officers relinquishing their temp. commns.: Temp. Capt. Kongattil Madhava Menon and Temp. Lt. J. T. Fernandez.

Lt.-Col. E. F. Harvey retires.

Maj. J. A. Shorten has been appointed Professor of Physiology, Medical College, Calcutta. Maj. W. C. Paton has been appointed to act as District Medical Officer, Malabar District, and Superintendent, Headquarter Hospital and Mental Hospital, Calicut, vice Lt.-Col. A. P. G. Lorimer, granted leave. Dr. Baldhadra Singh, Civil Surgeon, has been posted to Mirzapur. Capt. S. D. Gupta to be Second-in-Command, Indian Military Hospital, Nowshera, vice Capt. W. D. B. Read, vacated. Maj. R. F. Barnsley to be Officer Commanding British Military Hospital, Gharial, vice Maj. E. V. Whitby. Maj. C. Wilson to officiate as Officer Commanding British Military Hospital, Peshawar, vice Lt.-Col. P. C. Douglass, appointed officiating A.D.M.S., Peshawar District. Maj. K. K. Chatterjee, Additional Surgeon, Out-patient Department, Medical College, Calcutta, to be Honorary Assistant Surgeon, vice Rai Upendra Nath Brahmachara Bahadur, retired. Lt.-Col. W. J. Powell, Inspector-General of Prisons and Officiating Director of Public Health, Central Provinces, has been appointed Civil Surgeon, Pachmarhi. Maj. R. N. Kpadia to officiate as Officer Commanding, Combined Indian Military Hospital, Kohat. Dr. Lhawja Moinuddin, Director, Educational and Sanitation Department, Dr. Hurdiker, Dr. Sureti, and Dr. Clarke have been appointed delegates to attend the Seventh Congress of Tropical Medicine to be held at Calcutta in December.

"Audi alteram partem."

ALKALI TREATMENT OF SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—I was interested in Dr. E. H. J. Berry's article on this subject in THE LANCET of Oct. 22nd. As prominence has been given to this method of treatment lately some results I obtained four years ago may be of interest.

Dr. Berry assumes the toxic origin of scarlatinal nephritis and he has found that the administration of alkalis neutralises the effects of this toxin. He does not, however, indicate what he considers the nature of the toxin to be or the modus operandi of the alkalis. The toxic theory is generally accepted, but scarlatinal nephritis has also been attributed to the direct action of germs themselves and streptococci have been found to be present in the kidneys post mortem. Now it is well known that in cases of *B. coli* cystitis, where infection has occurred from below, a condition frequently met with in cases of puerperal infection, that the rapid change of the reaction of the urine from acid to alkali then back again to acid and so on, by the alternate administration of large dose of alkali and acid by the mouth the condition is quickly cured. In these cases the vitality of the organisms is apparently damaged by the rapid changing of the pH of the medium in which they are existing—viz., the urine—and are rapidly destroyed. This supposition is further supported by the fact that the treatment is only satisfactory if undertaken in the very early stages of the infection.

With such cases and the possibility that scarlatinal nephritis might be caused by the action of micro-organisms on the kidney in mind, I thought that if such were the case and if this treatment could be applied to scarlatinal nephritis the same results might be obtained. Two conditions would require to be fulfilled, the case would have to be treated early, and it would have to be possible to change the pH of the blood rapidly. Nephritis is, nowadays, a comparatively rare complication of scarlet fever; I was, however, able to obtain eight cases in a fairly short time. They were all hospital patients where the urine was tested every 12 hours, so treatment could be started within a few hours of the onset of symptoms. Without making any comment on the classification of nephritis I omitted the late albuminurias and only selected those cases which were frankly acute with a febrile reaction, diminished secretion of urine, albumin, blood and casts, no cases of the type showing œdema as the first symptom presented themselves.

In each case the urine at the onset was acid to litmus. Under these circumstances my practice was, in cases over 5 years of age, and only one was under this, to give sodii bicarb. in doses of 60 gr. every four hours for four doses or less if the urine became alkaline before; it was usually alkaline after the third dose. The reaction of the urine was noted each time it was passed and if scanty or difficult to obtain the patient was catheterised. In one patient under 4 years of age the dose was sodii bicarb. 30 gr. four-hourly; the urine became alkaline after the fourth dose. When the urine was definitely alkaline to litmus the patient was left for 24–36 hours, and if the urine was not then acid, acid sodii phosph. was given, when definitely acid alkalis were again administered, this time in smaller doses, until the urine became either alkaline or amphoteric; the treatment was then stopped.

The following notes briefly indicate the results obtained:—

In four cases the temperature was normal and the urine normal in quantity and perfectly free from albumin and blood on the fourth day after treatment was started. In one case the above results were obtained on the fifth day. In one case the temperature rapidly subsided and the blood cleared, but there was a faint trace of albumin until

ighth day. In one case a very faint trace of albumin emained for three weeks, and one case did not respond t all. This patient was a boy aged 12 years, who had a istory of kidney trouble and œdema several years before. 'wo of the patients developed rashes during the alkali reatment, one a blotchy erythema and one an urticarial ruption.

I am in no way pressing the theory of direct acterial action as the cause of scarlatinal nephritis. mentioned the matter in order to indicate the train f thought that prompted me to try the treatment. have no experimental evidence to offer in support of uch theory. I was unable at the time to make any aboratory investigations apart from microscopical xamination of the urine, consequently I have no vidence that the change in the pH of the blood was f sufficient degree or took place sufficiently rapidly o damage the vitality of any organism even had uch been acting locally, as in the cases of cystitis. t was my intention to make further observations, ut unfortunately during the last three years no pportunity has presented itself.

Dr. Berry is rather dogmatic in his conclusions, for must be remembered that 70–80 per cent. of scarlet ever patients will recover without any serious com- lication provided that they are suitably dieted and roper attention is paid to the condition of the throat. he statement "It seems obvious that alkalis should e given all the time the patient is considered infec- ous" appears to me to be somewhat exaggerated. ssuming a toxic cause for nephritis, then in five of y acute cases all that was necessary was the dministration of 190–240 gr. of sodii bicarb. within period of 12 hours to neutralise the toxic effects, r as soon as the urine was alkaline to litmus I llowed it to become acid again, and during this eriod there was no exacerbation of symptoms. ontinuous administration does not appear to have een indicated in these cases; again, in some of Dr. erry's own cases complications apparently occurred hile the urine was actually alkaline.

There seems to be room for further investigations ong such lines as: Assuming there is a scarlatinal oxin, in what way do alkalies render it inert? What e the indications for the administration of alkalis? hich is the best preparation to use and what is the ptimum dosage? Work along these lines would obably yield better results than the substitution of ie empirical method for another.

I am, Sir, yours faithfully,

H. J. PHILLIPS, M.D., B.Sc.

Oldham, Oct. 24th, 1927.

To the Editor of THE LANCET.

SIR,—The beneficial effects from the use of large oses of alkali in the treatment of scarlet fever, corded by Dr. Berry, prompts me to write this note. have for some time past been watching my cases, om the point of view of acidæmia and alkalæmia, id find the investigation most helpful. The former ndition I have referred to in former publications [1]; ie latter I am at present investigating, and find it not frequent (including the alkalosis that is already cognised as being present in acute high intestinal bstruction).[2]

The importance of the hydrogen-ion concentration the blood in its relation to disease was brought home me by a paper by Ellice Macdonald, of Philadelphia, n Chemical Aspects of Life and Disease,[3] in hich he points out that not only can the acid or kali state of the blood by itself cause ill-health, but iat they can predispose to certain illnesses—the pe of which varies with the underlying blood state. o put it shortly, he has shown by X ray meals of ie gastro-intestinal tract (postural tone) that the nooth muscle reaction, as he calls it, varies according as the blood swings to the acid or alkaline sides. In the former (acid) type the vagus autonomic system is in preponderance; in the latter (alkaline) the sympathetic is in predominance. Amongst the acid type he groups most infections; of which scarlet fever with its great tendency to acidosis, as pointed out by Dr. Berry, is one. Here, therefore, we find a rational explanation of the reason why alkalies are so beneficial—viz., that the blood state which predisposed patients to scarlet fever was already an acid condition of the system, with vagus preponderance, and that this acid state was increased by the scarlet fever organism. The use of the alkaline salts of potassium in these cases may not be without significance, as in another paper Macdonald [4] shows that potassium chloride is a stimulant to the sympathetic nervous system. This view of disease seems to me to promise a fruitful line for investigation.

SOME CASES OF ERYTHEMA NODOSUM.

To the Editor of THE LANCET.

SIR,—The occurrence of three cases of erythema nodosum in my practice early this year induced me some months ago to collect all the cases I had seen since 1918, and I was therefore particularly interested in Dr. Mitman's excellent account of a small outbreak of this malady and the lucid review of the situation in THE LANCET of Oct. 8th (pp. 751 and 761). I had come to the conclusion that erythema nodosum was a manifestation of what I am in the habit of calling by the handy name of "tonsillar influenza"—a type of tonsillitis which occurs during "influenza" epidemics. Since August, 1925, this type of influenza has been endemic in my practice (and I believe all over the country), and five out of the eight cases described below have been seen since April, 1926. Other interesting complications of this type of tonsillitis have been pulmonary infarction, "nephritis," "pyelitis," "hæmaturia," and unilateral effusion of the knee (non-rheumatic). I find that the occurrence of erythema nodosum coincides with the other complications, and whenever I see a case of the former I am on the look-out for cases of the latter.

The following are the histories of the eight cases; I refer to the pulmonary and renal cases seen about the same times.

(1) F., 18. Seen 8/5/20. Diagnosis: erythema nodosum. I only questioned the patient as to whether she had had rheumatism, and not realising the importance of tonsillitis I do not remember if the patient had had a sore-throat. My books show that tonsillitis was very prevalent at the time. I saw a case of pulmonary infarction following tonsillitis on May 8th and a case of puerperal cerebral embolism on May 12th.

(2) F., 27. Seen 1/11/20. Labelled "tonsillitis and erythema nodosum." Tonsillitis prevalent. No renal or pulmonary infarcts until following month.

(3) F., 20. Seen 13/2/25. Influenza epidemic. Labelled "erythema nodosum following sore-throat." Case of pyelitis on Feb. 9th, and two cases of pulmonary infarction on Feb. 24th and several in ensuing weeks.

(4) F., 29. Seen 31/3/26. Influenza prevalent. She had influenza and sore-throat. Later, jaundice was followed by severe pains in the legs and erythema nodosum was marked on April 12th. I had an epidemic of post-influenzal nephritis in March, saw a case of "hæmorrhagic nephritis" on April 5th, cases of pulmonary infarction on March 30th and April 8th (both following tonsillitis), and a post-operative pulmonary embolism on April 8th!

(5) M., 10. Seen 1/10/26. Tonsillitis. Oct. 5th: erythema nodosum. On Oct. 3rd I saw a case of pulmonary infarction and on Oct. 6th a case of renal infarction. Both were endocarditis patients suffering from influenza.

(6) F., 23. Seen 22/1/27. Influenza epidemic. Erythema nodosum and slight erysipelas of face following sore-throat. Case of influenzal nephritis on Jan. 26th, cases of pulmonary infarction (influenza and dilated hearts) on Jan. 18th and 31st, and a case of cerebral embolism (V.D.H.) on Jan. 23rd.

(7) F., 28. Seen 15/3/27. "Influenza cold." March 22nd: "neuritis in legs." March 24th: "erythema nodosum."

[4] Chemical Aspects of Life and Disease (continued), Ibid., July 7th, 1926.

The temperature kept up for three weeks but no explanation of it was made. This patient two years previously had a suppurating cervical gland, presumably tuberculous.

(8) F., 34. Seen 16/4/27. Influenza. Said she spat up something like jam (? small infarct) on 18th. On April 26th there was an extensive eruption of erythema nodosum on the fronts of the legs and backs of the arms. This patient had an attack in 1920 (same as No. 2), so that second attacks do occur. On April 13th an endocarditis patient with influenza and tonsillitis (her healthy sister had the same complaint) had a renal infarction.

All the patients were healthy subjects except No. 7, and in none of them was there the slightest evidence of an attack of true rheumatism. Probably the old observers confused post-influenzal neuritis with acute rheumatism—a mistake which is not uncommon to-day.

It is curious that seven of the cases were females. It is also curious that not a single case was seen in the extensive epidemics of 1918, 1919, 1922, and 1924. Renal complications were also rare in these epidemics. It seems, therefore, that there must be a particular germ or group of germs which favour the occurrence of these complications.

Is it possible that the eruption in these cases is due to thrombosis or embolism in the cutaneous vessels? It sounds far-fetched that such should occur in an area of free anastomosis such as the skin. Yet the site of the eruption—the fronts of the legs—is generally reckoned an avascular region.

Apropos of Dr. Mitman's use of the term "pseudo-lobar" pneumonia, I am of the belief that these cases are very often not pneumonia at all but pulmonary infarctions which have been mistaken for pneumonia. Without the appearance of characteristic blood sputa the diagnosis is extremely difficult.

I am, Sir, yours faithfully,

AMBROSE W. OWEN,
Hon. Surgeon, Aberdare General Hospital.

Oct. 27th, 1927.

RADIOPACITY OF GLASS.

To the Editor of THE LANCET.

SIR,—I am at present engaged in determining the opacity of various substances to X rays. The results of my investigations are not yet ready for publication, but as Miss Mann in her article on the Treatment of Perforating Injuries of the Eye in THE LANCET of Oct. 29th, says, ". . . even lead glass fragments may be localised, but the lighter forms of glass are transparent to the rays," I thought the following might be of interest.

I obtained specimens of various glass, consisting of pieces from an old X ray plate, a bottle, a window, an electric light lamp, a test-tube, and a piece of corrugated roof glass. I arranged these on an X ray film and took a radiogram. I then buried them in the middle of a piece of raw beef 5 in. in thickness and made a second exposure. All the glasses cast shadows. The pieces from the electric light lamp and the test-tube (the thinnest glass I could obtain) cast faint but nevertheless unmistakable shadows, even when embedded in the beef. I obtained these shadows when I used either hard or soft rays, and I used the ordinary exposure that I would use in taking a radiogram of an arm.

On consulting a book on glass-making I learn that the ordinary flint crystal or table glass contains oxide of lead and bottle glass oxide of iron. X ray books as a whole are curiously reticent as to the radiopacity of glass, and those that do mention it make contradictory statements. Holmes and Ruggles in their book say that fragments of glass may be missed, even in the thin tissue of the finger, while Bythell and A. E. Barclay state "even ordinary flint glass throws a shadow sufficiently heavy to be visible on the plate, provided that it is embedded reasonably near the surface," but I can find no reference to the visualisation of a piece of glass 2½ in. from the surface.

I am, Sir, yours faithfully,

Dublin, Oct. 29th, 1927. SYLVIA B. WIGODER, M.D.

A CASE OF CEPHALIC TETANUS.

To the Editor of THE LANCET.

SIR,—Dr. Macneill Simpson takes me to task i your issue of Sept. 17th for exaggerating the rarenes of cephalic tetanus by writing that "tetanus limite to the head and neck is very uncommon." Perhap I have been misled by my own experience to thin it more uncommon than it is, for the case describe by Dr. J. P. Fitzpatrick and myself in THE LANCE of Sept. 10th is the only one of the kind which I hav seen during 25 years' service in the Eastern tropic Judging, however, from such records as I have read it is rare for the spasms, in so severe a case, to b confined to the head and neck. In one of the fou cases described by the late Sir George Humphrey in the article cited by Dr. Simpson, there were fr quent severe spasms of the body muscles; in anothe there was opisthotonos; and, in the two remainin cases, the abdominal muscles were involved.

In our case there was, unfortunately, but little t be hoped from treatment; the patient could n swallow, and, as Sir George Humphrey wrote Allbutt and Rolleston's "System of Medicine," whe food cannot be swallowed recovery rarely tak place, and nothing can be relied upon even to pos pone the fatal event." Tetanus antitoxin was give from the day of the patient's admission to hospita though little benefit could be expected from it; fo as far as could be made out from the somewhat vag history, the first symptoms had appeared about week before. Rectal injections were returned at on unless the patient was kept under an anæstheti The wound was healed and no local interferen was indicated. Apart from the administration antitoxin, treatment was limited to attempts get fluids and carbohydrates into the patient, ar to alleviating his sufferings with sedatives ar anæsthetics.

There was no asphyxia or indication for the trache tomy which gave relief in one of Sir George Humphrey cases.—I am, Sir, yours faithfully,

WILLIAM FLETCHER.

Kenilworth, Warwickshire, Oct. 27th, 1927.

RECTAL INJECTION OF VOMITED BILE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of August 13th last, Mr. St. Leger Brockman brought forward evidence show that the toxæmia and vomiting which accompa intestinal obstruction were mitigated by rec injection of human bile diluted with saline. A p portion of cases of gastro-enterostomy vomit b after operation. Usually this ceases within 48 hou but the longer it lasts the more anxiety it caus To return this bile mixed with rectal saline is at on so simple, convenient, and harmless, that if it is n to become an immediate routine procedure, it c tainly warrants an extended trial. Personally, I ha been favourably impressed by the method, and belie it will reduce the number of cases requiring gast lavage. I am, Sir, yours faithfully,

Birmingham, Oct. 29th, 1927. HAMILTON BAILEY.

DIABETES WITH RENAL GLYCOSURIA.

To the Editor of THE LANCET.

SIR,—Abnormal permeability of the kidneys glucose is not very uncommon in diabetes, and, Dr. Voigt (THE LANCET, Oct. 29th, p. 916) has fou its presence complicates the insulin treatment. a rule, the lowering of the renal threshold, in m experience, is associated with, and appears to dependent upon, a low calcium content of the blo for when the calcium is raised to the normal le by treatment glycosuria does not occur unless hyp glycæmia is present. The defect of calcium metaboli responsible for the condition probably arises fr disturbances in the functions of the parathyro

used by chronic toxæmia, most likely in Dr. Voigt's se of intestinal origin, hence the administration of rathyroid with calcium salts and removal of the use of the toxæmia bring about more permanent provement than calcium salts given alone, as pointed out some years ago ("New Views on abetes," 1923, p. 392).

The failing sight, mentioned in Dr. Voigt's case, interesting; I have noticed that disturbances of ion are more liable to occur in diabetics with a r percentage of calcium in their blood than in hers, and that measures which increase the calcium quently give better results than simple treatment the defect of carbohydrate metabolism.

I am, Sir, yours faithfully,

P. J. CAMMIDGE.

ottingham-place, Marylebone, W., Oct. 29th, 1927.

PAYMENT TO HOSPITALS FOR MOTOR ACCIDENTS.

To the Editor of THE LANCET.

IR,—I regret that Dr. Fothergill, whose letter ears in your issue of Oct. 29th, has been misled some loose wording in a printed report. Of course is right—the only contracts are as between the rance company and the patient on the one hand the practitioner and the patient on the other. ever said that the practitioner could send his bill he insurance company. But what we do hope is , by using the machinery of the paying ward, a can be sent in which will eventually take its place ng the other expenses forming the basis of the im's claim upon his insurance company.

s a matter of common practice, based entirely upon venience, a practitioner's bill may occasionally be direct to an insurance company, but nobody ought uppose that this recognises any contract between e parties. So much of what insurance companies out is based upon claims which would not be lly binding were the matter brought into court. do we imagine that the companies will treat the ng ward of a hospital less generously than they in the habit of treating doctors in such cases, the position is established of these wards being led to make contracts with patients which are not ible on the part of a voluntary hospital under nary conditions.

bviously the matter is of growing importance to lospitals, and it is essential that the legal position ld not be misunderstood from the start.

I am, Sir, yours faithfully,

PHILIP T. CARILL-WORSLEY,
Vice-Chairman,
Norfolk and Norwich Hospital.

t. 29th, 1927.

MISLEADING QUALIFICATIONS.

To the Editor of THE LANCET.

R,—In the course of his reply to critics, "Ethics" s: "In the surgical world the English Fellowship cognised to be the highest surgical distinction," adduces as evidence for this statement, "it is a bulsory passport to admission to honorary surgical intments in all teaching English hospitals," ng "many Edinburgh and Irish Fellows avour to obtain it after acquiring their own." matter of fact, in Scotland and Ireland the ish and Irish Fellowships are compulsory pass- for similar posts. Is it to be inferred that ish and Irish hospitals are not equal to those of and, or their staffs not as efficient? Many ws of all the Colleges take the M.D. and M.R.C.P. as higher distinctions but as additional fications.

to the F.R.C.S. Edin. not being a purely cal distinction, I do not agree with "Ethics." ndidate for the Edinburgh Fellowship has to a special examination in surgery, plus a special ination in the subject he professes, and if he ds to practise operative surgery he has to ate on the dead body. Surely this is sound. An English Fellow may practise gynæcology or dentistry without having been tested in these subjects in his Fellowship examination. In this respect I consider the Edinburgh Fellowship is in advance of the English. True there is no "primary" in the Edinburgh diploma; but the English "primary" is not surgery, and the intending Edinburgh Fellow has to satisfy the examiners as to his knowledge of anatomy—no easy matter.

Surely it is really a matter of custom and possibly—I have not verified the fact—the English College may be senior. F.R.C.S. stands for Fellow of the Royal College of Surgeons without specifying which. Those of us who hold the Fellowship of Edinburgh and add Ed. do so because we are proud of it and do not wish any mistake made. Let the F.R.C.S. England add Eng. and all will be well.

I am, Sir, yours faithfully,

Oct. 29th, 1927. F.R.C.S. EDINBURGH.

*** We have received other letters in reply to "Ethics." The writer of one of the most vigorous of these holds the Double Fellowship, but has omitted to enclose his card.—ED. L.

REGISTRATION OF NURSING HOMES.

To the Editor of THE LANCET.

SIR,—We feel that the public (your readers) are not sufficiently aware of the dangerous provisions that have been inserted in the "Nursing Homes (Registration) Bill." These place the duty of inspecting nursing and maternity homes in the hands of the smaller local authorities (in many cases the rural or district councils), and propose the repeal of Part 2 of the Midwives and Maternity Homes Act, 1926. This Act, which has been working satisfactorily since passed, placed the inspection of maternity homes under the same authority as the midwives, the county councils, and the county borough councils. If the new Bill, as amended, is passed, the result will be—dual inspection, the home being under one authority and the midwives working in it under another, with conflicting rules and regulations; the possibility, so undesirable in administrative work, of the influence of personal friends and vested interests; and the certainty that the smaller authorities would not be able to provide well trained, whole-time inspectors with expert knowledge.

I am, Sir, yours faithfully,

L. RAMSDEN,
President, Midwives' Institute.

12, Buckingham-street, W.C., Oct. 31st, 1927.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the Case Committee 50 cases were considered and £648 was voted to 44 applicants. Below is a summary of some of the cases relieved.

Widow, aged 67, of M.D. who died in 1894. Only income 10*s.* a week from Government for son killed in the war. Son, aged 35, lives at home and the responsibility of the home falls on him; at the present time he is only earning £2 a week after being out of work for some time. Applicant has had many money losses and, as she has to keep her daughter at home to look after herself and the cottage, asks the Fund for help. Rent of the cottage, 10*s.* a week. Voted £24 in quarterly instalments.

Widow, aged 47, of M.R.C.S. who died last month. Late husband was in receipt of a grant from this Fund of £40, £20 of which had been paid. Applicant asks that the balance may be transferred to her. The Committee acceded to her request.

Daughter, aged 52, of M.R.C.S. who died in 1907. On the death of her father took a boarding-house which she was obliged to sell up in 1925 owing to ill-health. On regaining her health took up domestic work, and in June this year took another house in which she has let unfurnished rooms; she retains two for herself to carry on a sewing business. Voted £25 to meet rates and to buy some furniture for her room.

Widow, aged 59, of L.S.A. who died in 1914. Left with five daughters, two of whom are black-and-white artists, one a nursery governess, and the two youngest modellers. Owing to trade depression she has not been able to meet rates, and £20 was voted to meet these and other debts.

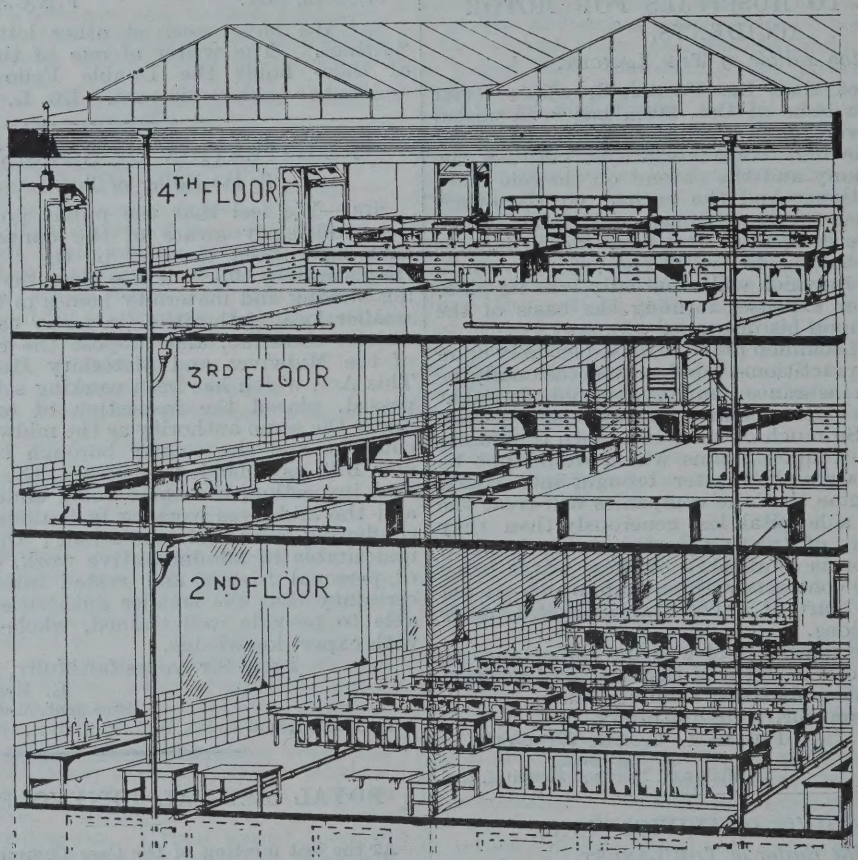
Subscriptions may be sent to the hon. treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

WELSH NATIONAL SCHOOL OF MEDICINE:

NEW MEDICAL UNIT LABORATORIES.

THE new laboratories of the medical unit of the Welsh National School of Medicine have just been completed at the Cardiff Royal Infirmary. They have been erected on the site of the old casualty department of the hospital, which opened out of the south side of the main hospital corridor between the entrance block and the Insole ward block. The cost of the building and part of the equipment have been provided through the generosity of the Rockefeller Foundation, New York.

The laboratory block consists of ground, first, second, third, and fourth floors; an internal staircase in the new block, on the side adjoining the hospital wards of the unit, gives access from floor to floor. Owing to the difference in levels of the new floors from those of the hospital, the five storeys of the laboratory block occupy the same height as the four main hospital storeys; there is intercommunication between the new staircase landings and the hospital corridors on the ground, first, second, and third floors of the hospital. There are, in addition, external iron escape ladders on the north side of the laboratory block from the fourth floor to the third floor roof below, from which the hospital second floor corridor may be reached through a window; and from the second floor to the roof over the main hospital corridor on the ground floor below. Thus, in the event of a fire filling the new staircase with smoke, there is an alternative route to the ground from every floor.



The Medical Unit Laboratories, Welsh National School of Medicine. Showing in detail the lay-out of the three upper floors.

The new block is lighted from the south on the ground floor, and from the north, south, and west on all the upper floors; and in addition the second and fourth floors have skylights, so that every laboratory and room has ample illumination.

Externally, the walls are faced with Cattybrook bricks from Bristol, similar to those used throughout the hospital. The stone sills, strings, and copings are Forest of Dean stone. All floors are of the "Kleine" fire-resisting reinforced terra-cotta construction, as are also the roofs. The stairs are of patent stone, with carborundum treads. Internally, the floors are covered with teak blocks on the ground floor and with cork parquet on all the other floors except in the avatories and store cupboards off the stair landings, where they are of patent stone. The walls have tiled dadoes on t staircase and on all floors except the first, where the st rooms are situated. Above the tiled dadoes the walls finished in Keene's cement and distempered.

All floors are heated by hot-water radiators connected a new calorifier installed in the old basement beneath t block. This calorifier is heated by steam taken from t main boilers of the hospital. In addition, the staff roo on the first floor have gas fires. All the laboratory benc are of oak with teak tops, fitted with gas and electric plu and water, and the whole building is lighted by electrici Separate electric and gas mains supply this block, and water-supply comes through a separate meter.

General Arrangement of the Laboratories.

The general arrangement of the laboratories is follows.

On the ground floor folding teak doors open fr the main hospital corridors into a small lobby fr which the staircase rises to the upper floors. T ground fl contains t research l oratori fitted up e xperimer work and photograp dark ro One labo tory is 27 by 21 ft. 6 and the o 21 ft. by ft. Both 12 ft. h In the pa tion wall tween the there is a v roller shu which ca raised or ered at so as to vert the laborato more or into on requir Ample tric po and li plugs are vided in ceiling ar the walls gas, ele plugs, water tap fixed on benches the win Large

with hot and cold water are also fitted separately the benches. A three-way cable and telep communicating with the medical unit wards are for electrocardiographic work, and a floor plug lead to earth is fixed.

On the *first floor* are the staff rooms and offic 8 ft. 6 in. high. The professor's room is 21 ft. 6 i 21 ft.; the other rooms are 21 ft. 6 in. by 1 21 ft. by 15 ft., and 17 ft. by 16 ft. 6 in. The fessor's room is in telephonic communication all the floors, and an outside telephone as well intercommunicating departmental telephone is inst in a telephone box in the office. On the landi this floor are a lavatory and three store rooms.

On the *second floor* are the two teaching la tories for students. One, the clinical pathology bacteriology laboratory, measures 37 ft. by 21 ft. high, and is lighted on the north, south, and sides. Bench accommodation for 30 studen provided. The benches face north, and a sky

nning along this aspect of the laboratory over the ndows, gives additional lighting. Behind the idents' benches there is a free floor space of ft. 9 in. by 13 ft. 7 in. Benches for sterilisers, ntrifuges, shakers, &c., are provided and large shing-up sinks fitted.

The other laboratory on this floor is the students' oratory for biochemistry. It measures 37 ft. by ft. by 12 ft. high, and is lighted on the north and ith by the ordinary windows, but there is also a ylight running along the north side of the laboratory, ur large double chemical benches are fitted, pro- ling accommodation for 32 students if required; ge washing-up sinks, fume cupboards, balance nches—specially lit—benches for centrifuges, ikers, &c., and a draught cupboard for stills, ffle-furnaces, &c., are fixed in different parts of laboratory. A polarimeter room, lavatory, and re rooms are located on the staircase landing of s floor.

The *third floor*, which is 9 ft. high, contains research oratories for clinical pathology and bacteriology, l serological work. The former measures 28 ft. 22 ft. and is lighted on the north, south, and west lls; in addition to fitted benches all round, two vable tables are provided and electric light and ver plugs are fixed over them. The serological oratory measures 17 ft. 8 in. by 14 ft. 6 in. and is ited on the south wall. A bench with thick riolite top is fixed along the south wall and benches baths, &c., are also provided. A media-preparation sterilising room, 21 ft. by 13 ft. 6 in., is also included his floor. Opening off the adjoining landing are a (incubator) room, 9 ft. 4 in. by 7 ft., electrically ted, and a store room for refrigerator and large trifuge. There is also a lavatory on this landing.

The *fourth floor* consists of one large biochemical arch laboratory measuring 43 ft. 6 in. by 28 ft. 6 in. s lighted on the north, south, and west sides and two large skylights. Four large double research mical benches are fitted each 12 ft. by 4 ft. 6 in. 3 ft. high—and in addition there is another chemical ch running along the south side of the laboratory. ance benches, specially illuminated, are fitted g the north wall, and six fume cupboards, one ially enclosed draught cupboard, and benches electric shakers, stirrers, centrifuges, &c., are vided.

special feature of the laboratory block is its close ximity to the medical unit wards. A doorway from internal staircase of the laboratory opens on to top floor corridor of the hospital and is within ards of the medical unit wards.

The architect, Mr. E. Stanley Hall, F.R.I.B.A., e firm of Edwin T. and E. Stanley Hall, London, ently gave effect, with close attention to detail, he wishes of Prof. A. Mills Kennedy, the director e medical unit, and both deserve congratulations he result of their labours.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Local Appointments.

is satisfactory to note that the outcry against new method of appointing the officers of local orities is receiving no sympathy from responsible sters. Replying to a question in the Dail last President Cosgrave took the opportunity of nding the procedure followed by the Appointments missioners. He said that it had not been the tice of the Local Appointments Commissioners to ish a list of the qualifications of unsuccessful idates for vacant posts. In settling their practice objects of the Commissioners were primarily to re the election of the best qualified candidate, and ntally to relieve members of local authorities the embarrassment caused in the past by npts on the part of candidates to advance their candidature through the exercise of local influence. The submission of the names of all qualified candidates was not calculated to achieve these objects, and if any name other than that of the best qualified applicant were submitted it would be very difficult, if not impossible, to justify the exclusion from the list of any qualified candidate. Furthermore, if the names of the qualified candidates were forwarded in their order of merit those candidates who had failed to obtain a high place might with reason be apprehensive lest the publication of such a list would adversely affect their professional prospects.

In a letter to the daily papers, published on Oct. 31st, Dr. T. Hennessy analyses the qualifications of three candidates recently appointed to dispensaries in the county of Dublin. These appointments had been the mark of severe—and, as Dr. Hennessy shows—unwarranted criticism by one of the local authorities concerned. These candidates all had good records, as he showed, but the nature of the criticism made it clear that none of them would have had any chance of election under the old system unless, in addition to his professional qualifications, he had possessed local or family influence with the members of the local authority. A system which makes it possible for such candidates to obtain appointment on their merits alone is a great reform in administration.

THE NEW R.A.F. HOSPITAL.

EQUIPMENT AT HALTON.

ON Monday last the Royal Air Force's hospital and nursing sisters' quarters at Halton, near Wendover, were formally opened by Princess Mary Viscountess Lascelles.

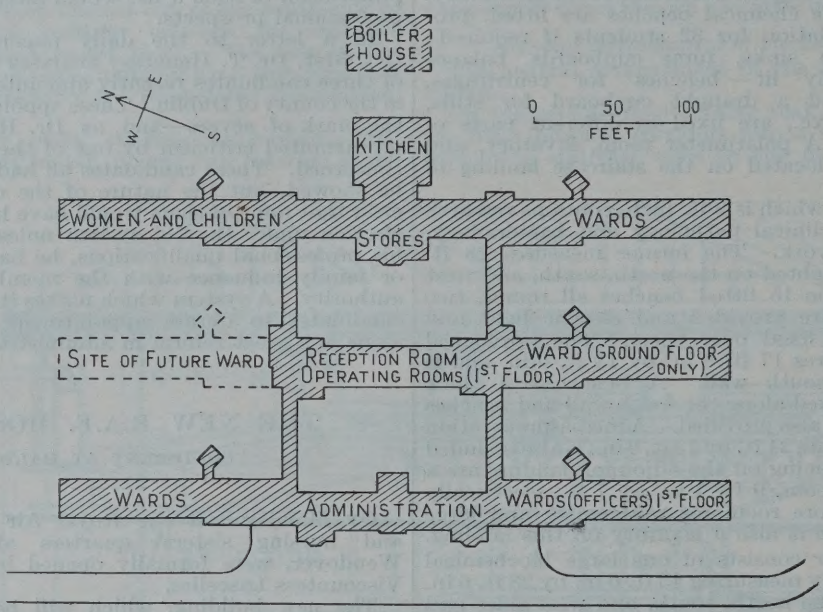
The new building, which will be called Princess Mary's Royal Air Force Hospital, is built in two storeys of pleasant-coloured red brick. It is sheltered from the north and east by a ridge of the Chilterns and overlooks a beautiful valley. Its position as well as its construction ensure that ventilation—the first need of a hospital after shelter—shall be adequate. At present there is accommodation for about 200 beds, but there is room for expansion. The general design may be seen in the plan which we reproduce below. There are a medical and an acute medical ward, a surgical and an acute surgical ward, a mental ward, two wards for apprentices, a section for officers (some small rooms, a ward for a dozen patients, a dining room, a library, and a billiard room), a section for women and children, and a labour ward.

The ward units are good. On one side of the entrance is the sister's room with an ice-chest, the scullery with a gas oven and rings, and a store; on the other side is a special ward with one or two beds, a recess with a steam steriliser for instruments, a recreation room, and annexes with three water-closets (elbow rests to each), a lavatory and a bath, also a room for bedpans with a large slab for scrubbing mackintoshes. All the taps are white; there is little or nothing to polish. The ward itself has 23 beds, painted buff with a slightly darker dado toning with the rubber carpet on the floor, and a dull red surround to meet the rounded edge of the walls. Windows alternate with the beds; each is iron-framed, in three sections and pivoted horizontally, so that ventilation is easy. The window-sill is of white enamelled rounded bricks, and below each is a sufficient radiator, so that draughts are not felt. These radiators are the principal source of heat, but there are also two coal fires (whose smoke escapes through floor ducts) to add to the patients' comfort in cold and stormy weather. Green curtains shade the windows. Lighting is central, by eight large lights over the foot of the beds, but there are also movable lamps at the bed-heads. Each bed has a chair, and a bed-table with two shelves, and a rail at the back for the damp towel. The children's ward has a frieze

of grotesque animals—rather a breakaway from Government tradition.

The mental ward has been well planned. A spring bolt on the door of the padded room holds the door as soon as it is shut, and if the orderly cannot see all he wants through the window, he may slip on a strong chain and open the door without fear that the patient will push past him. Here is the detention ward which will be little used, for it is found that prisoners, if put on their honour not to give trouble, can as a rule be safely trusted in the ordinary wards.

Two large dining rooms are provided for convalescents; one of them is also a recreation room and has a piano, a gift from the sergeants' messes of connected stations, and the nucleus of a hospital library. There are two boilers; one heats the radiators, the other provides steam for cooking, sterilising, and heating water for the lavatories. Vegetables and puddings are cooked by steam, roasting and grilling is done by gas, and there is also a coal range. Vegetables are prepared for cooking outside the kitchen, across a yard, so as to keep dirt off the premises. At the hospital end of the kitchen is a large hot-plate, and beyond that a counter where the wards receive their diets in highly polished, covered boxes; in the wards the food is divided to the patients by the sisters. An ice-store below the dispensary is connected by a lift with the floors above. Passages throughout the hospital are covered with corticine, which makes for comfort and quiet; corners are everywhere rounded and there are few dust-traps. People always kick a swing door open. Here a rubber patch is provided for them to kick.



Plan of the R.A.F. Hospital at Halton.

The reception room at the main door has lavatory accommodation opening off it on one side, whilst on the other are the medical officer's rooms, one of which is fitted out for making examinations. In another part of the building are quarters for the orderly medical officer, and the commanding officer and his registrar. The staff have good offices and there are eight medical officers. The orderlies are well lodged, their rooms have fireplaces, and corticine on the floors. There are steel lockers for their clothes, and in suite with each room are w.c.'s, upright slab urinals, washing basins, and douche and slipper baths. The orderlies' kitchen and dining room are in another building. The sergeants have a very comfortable mess, whose rooms can be thrown into one for dances. The married quarters of the station are all around the hospital. They are cleverly planned so that rooms on the border between houses can be assigned to either as the families require.

Accessory services are the powerful X ray plant with its photographic rooms, the hospital clinical laboratory (the Central Air Force laboratory is close by, but independent), the electrical, massage, and gymnastic appliance rooms, and the ophthalmic room. The septic and aseptic operating-theatres on the first floor are painted in green. The north wall of the aseptic theatre is almost all glass, most of it single huge sheet affording a beautiful light. Ov the table is a new shadowless lamp. The lighting the theatre is double, and the constant glow of small red lamp shows that the emergency circuit ever available. The floor is terrazzo, very smooth a easy to clean, but with little strength in itself. Besi the theatre are rooms and a bath for surgeons, and t sisters have equal consideration. The new sisters' ho consists of 38 rooms with a small hospital for t sick. The quarters about 200 ya from the h pital, and th are rooms their cloaks each end of t building.

In the iso tion hospital some half doz observati rooms for t patients, ea entered o from the o air, but in walls are la glass panels p mitting t sister when one ward to k an eye on others. Separ from the m building is venereal secti 25 beds in a h very spars occupied, w the usual tre ment rooms. Every endeavour is being made to cases to report early so as to shorten the treatmer

The hospital has now been in use for nearly th weeks. Apart from the fact that the building not been wired for wireless whilst being erected, wh might have saved expense, it is difficult to find fa with the arrangements, for the planning has b most judicious. Nothing seems to have been was on ornament, but the appropriateness of everyth makes the place very handsome.

We offer our thanks to Wing-Commander W. Shorten, who is in command, for the trouble he t to show and explain the hospital to our representati

---

MEDICAL CONGRESS IN EGYPT.—A congress to known as "Journées Médicales d'Egypte" is to held Cairo from Dec. 15th to 24th. The voyage and confer will involve an absence of from 20 to 22 days from Marsei French, English, Arabic, German, and Italian will be official languages used, and there will be an internati exhibition of arts and sciences as applied to medic surgery, pharmacy, and sanitary hygiene. Further ticulars may be obtained from Dr. Zeitoun, 32, Gay-Lussac, Paris (Ve).

CANCER RESEARCH HOSPITALS.—The governors Middlesex Hospital are appealing for the means of pla the old Cancer Charity, now renamed the Middlesex Ca Hospital, on a self-supporting basis and, if possible extending its accommodation. The charity was four 135 years ago. The governors feel that if cancer pati are to be induced to submit themselves to treatment in early stages of the disease the accommodation must increased.—At St. Mark's, City-road, E.C., the Lord M of London last week opened a new wing. The exten includes two wards which will increase the in-pat accommodation by 18 beds, making a total of 72, an patients' department, and nurses' quarters. The cost been £23,000, of which £3000 remains to be raised. It stated that medical men from all parts of the world com St. Mark's cancer research laboratories to study the met to the hospital.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a Congregation on t. 28th the following degrees were conferred :—

M.D.—C. E. Newman.

M.B., B.Chir.—G. B. Woodd Walker and G. A. Q. Lennane.

B.Chir.—F. H. A. Walker.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—A ordinary quarterly comitia of the College was held Oct. 27th, the President, Sir John Rose Bradford, being the chair. The following candidates, having satisfied e Censors' Board, were admitted to the Membership :—

Drs. Ivan McDonald Allen, Doris Manning Baker, Donald Davidson, Henry Victor Dicks, Andraous Erian, Noel Trelawney Glynn, Wesley George Catchlove Godbehear, John Gerald Edward Hayden, Edward Humphry Vere Hodge, Eric Canton Seward, George Ernest Frederick Sutton, John Martin Twhigg, Lionel Ernest Howard Whitby, and Maurice Lindsay Young.

Licences to practise were conferred upon 175 candidates (3 men and 22 women) who have passed the final examina- n in medicine, surgery, and midwifery, and have complied h the by-laws of the College. The following are the nes and medical schools of the successful candidates :—

Mary E. A. Allen, Birmingham ; F. W. Allinson and S. W. Allinson, Univ. Coll. ; J. V. Almeyda, Bombay and London ; Joan Anderson, Manchester ; B. J. E. Anson, King's Coll. ; C. Arkles, Guy's ; M. I. Ashmawi, Cairo and St. Thomas's ; P. V. Bamford, Bengal and London ; O. A. Beadle, Oxford and Guy's ; W. J. H. M. Beattie, Cambridge and St. Bart.'s ; C. A. Bence, Cardiff ; F. W. Besley, Cambridge and London ; H. R. P. Boucaut, Adelaide and London ; A. R. Bowtell, Oxford and Univ. Coll. ; W. V. Boyle, Cambridge and London ; W. E. R. Branch, Univ. Coll. ; D. H. Brinton, Oxford and St. Mary's ; Ruth M. Brittan, Royal Free ; L. Brown, Cape and Guy's ; J. R. Buchanan, Univ. Coll. ; E. S. Caley, St. Thomas's ; C. S. Carter, St. Mary's ; B. W. Cartwright, Birmingham ; A. J. W. Chamings, Cambridge and St. George's ; W. A. Clark, St. Bart.'s ; E. Clayton-Jones, Cambridge and Guy's ; Amy G. Clogg, Cambridge and King's Coll. ; M. Coleman, Univ. Coll. ; M. Coll, Durham ; N. B. Colman, Witwatersrand and St. Bart.'s ; A. W. Cubitt, Oxford and King's Coll. ; E. G. C. Darke, St. Bart.'s ; Ethel G. Davies, Cardiff and Royal Free ; S. B. Davis, Oxford and London ; R. de Sousa, Bombay and London ; P. M. Deville, Guy's ; W. E. Dornan, Leeds ; C. H. Egan, South Africa and Guy's ; Antoinette H. P. Ellis, Charing Cross ; D. Ellis, Guy's ; S. Farfel, Witwatersrand and St. Bart.'s ; C. J. Farr, King's Coll. ; H. G. Floyd, Guy's ; Helen M. G. Foster, Univ. Coll. ; J. L. Franklin, Cambridge and St. George's ; L. W. Freeman, St. Mary's ; C. R. E. Freezer, Guy's ; T. O. Garland, Cambridge and Guy's ; S. Gifford, St. Thomas's ; Edith Giles, Charing Cross ; G. G. Gillam, Univ. Coll. ; Barbara M. L. Glover, Royal Free ; P. S. Goonewardene, Ceylon and Middlesex ; E. L. Graff, Cambridge and Guy's ; A. W. T. Green, Middlesex ; F. Grundy, Leeds ; Brenda G. Hallett, Royal Free and St. Mary's ; A. S. Hatch, Univ. Coll. ; W. J. Heely, Guy's ; R. A. Hill, St. Thomas's ; L. T. Hilliard, Cambridge and St. George's ; W. A. C. Horter, Middlesex ; Esther M. Hoskin, King's College ; G. McI. Housden, Guy's ; Lilian J. Hubble, Royal Free and King's Coll. ; E. C. H. Huddy, Guy's ; E. H. Hudson, Cambridge and Guy's ; W. F. Hudson, Guy's ; T. I. Hughes, Bristol ; F. H. Hunnard, Univ. Coll. ; W. A. Hutton, St. Bart.'s ; S. Inder Sen, Punjab and London ; G. L. M. Inkster, Oxford and Middlesex ; E. D. Irvine, Liverpool ; E. T. James, Cambridge and St. Bart.'s ; T. E. James, Cardiff ; B. R. M. Johnson, Middlesex ; R. E. Jones, Birmingham ; D. F. Kanaar, Guy's ; C. A. Keele, Middlesex ; W. R. Keizer, London ; Rachel I. Kessel, Charing Cross ; H. A. Kidd, St. Mary's ; K. Knowles, St. Bart.'s ; E. Landau, Cambridge and St. George's ; L. E. Lane, Cape and Guy's ; I. W. Lazarus, London ; J. T. Lewis, Cardiff ; M. J. Liberson, Durham and Middlesex ; A. W. Lilley, Manchester ; Edith G. Limmex, King's Coll. ; F. E. Lipscomb and D. H. Lloyd, Middlesex ; J. Lloyd, Cardiff ; A. Long, Leeds ; P. H. Loretz and W. S. McConnell, Guy's ; A. M. McMaster, St. Bart.'s ; H. I. Maister, Guy's ; H. E. Mansell, Oxford and St. George's ; Beryl L. Mappin, St. Mary's ; W. H. Miller, Guy's ; W. Milligan, Leeds ; D. P. Mitra, Harvard and Charing Cross ; R. V. Mone, Bombay and St. Thomas's ; A. M. A. Moore and P. H. L. Moore, London ; D. T. R Morris, Univ. Coll. ; T. C. Mort, Cardiff ; T. Morton St. Thomas's ; Gertrude M. Nicholson, Durham ; W. A. Nicholson, Cambridge and St. Bart.'s ; A. T. Pagan, St. Bart.'s ; W. R. S. Panckridge, Middlesex ; M. D. Patel, Bombay ; M. N. Patel and A. Peacock, London ; J. R. Peacock, Cambridge and St. George's ; G. M. Phadke, Univ. Coll. ; L. M. J. A. Pilot, St. George's ; G. W. Pimblett and D. Preiskel, St. Bart.'s ; W. J. E. Radford, Guy's ; P. R. Rainey, St. Bart.'s ; B. D. Rawlin, Sheffield ; B. R. R. R. Reddy, Mysore and Durham ; W. G. Rees, Oxford and King's Coll. ; W. V. Roache, I. M. Robertson, and R. Roderick, St. Bart.'s ; R. Rose, Middlesex ; Mona M. Russell Cruise, Royal Free and St. Mary's ; A. de la C. Russian and P. G. Salt, St. Bart.'s ; J. I. Sapwell, Cambridge and King's Coll. ; R. Saran, Calcutta and London ; S. Scheinfein, Univ. Coll. ; T. G. Scott, Guy's ; H. Shenouda, Cairo and Manchester ; V. C. Shroff, Bombay and Westminster ; Catherine E. M. Siddall, Royal Free and St. Mary's ; E. J. Silverman, Middlesex ; T. E. N. Simpson, Liverpool ; M. R. Sinclair, Cambridge and St. Bart.'s ; E. T. O. Slater, Cambridge and St. George's ; Felix Smith, Birmingham ; Fred Smith, Cambridge and London ; G. H. A. Soysa, Ceylon ; E. T. C. Spooner, Cambridge and St. Bart.'s ; Joan Staddon, King's Coll. ; R. J. Steeds, Univ. Coll. ; T. R. Stevens, St. Thomas's ; D. W. Stuart, King's Coll. ; J. H. R. Thomas, Cardiff ; L. G. Thomas, Liverpool ; Doris H. Tomes, Westminster ; Sybil E. Tremellen, King's Coll. ; S. L. Tunnicliffe, Liverpool ; L. P. Tupling, Guy's ; H. L. Vaidya, Bombay and London ; Isabel Vallance, St. Mary's ; J. H. Wainwright, Cambridge and Westminster ; Nora W. Wamsley, Charing Cross ; A. J. Watson, Middlesex ; J. R. S. Webb, St. Thomas's ; W. A. S. Welsh, Birmingham ; A. R. N. Whitlow, Univ. Coll. ; P. C. Wickremesinghe, Ceylon and Guy's ; J. W. Wigg, Univ. Coll. ; W. J. Wilkin, Cambridge and St. Bart.'s ; G. H. J. Williams, Cardiff and London ; S. T. Williamson, Guy's ; W. A. Wood, St. Bart.'s ; and E. C. Wynne-Edwards, St. Thomas's.

On the nomination of the Council, Dr. Robert Arthur Young, Dr. Joseph Shaw Bolton, Dr. Grafton Elliot Smith, and Sir Percy Bassett-Smith were elected Councillors to take the places of Dr. A. G. Phear, Sir StClair Thomson, Dr. Bedford Pierce, and Sir Leonard Rogers.—Sir Francis Champneys was re-elected a Representative of the College on the Central Midwives Board.—Dr. R. A. Young was reappointed a member of the Committee of Management.—The President announced the award of the Jenks memorial scholarship for 1927 to James Ramsay Muirhead Martin, formerly of Epsom College.—The President announced the appointment of Dr. A. G. Gibson to the Bradshaw lectureship for 1928, and of Dr. J. Graham Forbes to the Milroy lectureship for 1929.—The President announced the award of the Gilbert Blane gold medal to Commander A. W. McRorie, M.B., R.N.—The President announced that the adjudicators have awarded the Weber-Parkes prize to Dr. A. Stanley Griffith, of Cambridge.—Among others, communications were received from : (1) Dr. J. G. Taylor, of Chester, asking the College to accept his resignation of the Fellowship. This was accepted with regret. (2) The British Pathologists Association, asking the College to consider the desirability of instituting a special Diploma in Pathology. The President nominated a Committee to consider the question and to report to the College. (3) The War Office, inviting the College to send a representative on the Organising Committee of the International Congress of Military Medicine and Pharmacy to be held in London on May 6th to 11th, 1929. The President was appointed to represent the College. (4) Mr. F. G. Hallett, expressing his appreciation of the action of the College on his retirement from the office of Secretary to the Conjoint Board.—A report was received from the representative of the College on the Committee of Management of the Chelsea Physic Garden, and ordered to be entered on the minutes.—A report was received from the Committee of Management recommending that the Universities of Cologne and Barcelona, and the University of Tennessee College of Medicine be added to the list of institutions whose Graduates in Medicine are admissible to the Final Examination in Medicine, Surgery, and Midwifery. The Committee further reported that they had recognised courses of instruction at the following institutions—viz., D.P.H. Examination : the Haffkine Institute, Parel, Bombay ; the London School of Hygiene and Tropical Medicine (the five months' course recognised for the course of parasitology only) ; and the University of Lucknow.—The Committee reported the retirement by rotation from the Committee of Dr. R. A. Young and Mr. F. J. Steward.—After some formal College business, the President dissolved the comitia.

GRESHAM COLLEGE.—Four lectures on Insanity and History of its Treatment will be delivered at 6 P.M. on Monday, Tuesday, Thursday, and Friday, Nov. 7th, 8th, 10th, and 11th, by Sir Robert Armstrong-Jones, at Gresham College, Basinghall-street, E.C. 2. Admission free.

OPTICAL SOCIETY.—The next meeting will be held at the Imperial College of Science on Thursday, Nov. 10th, at 7.30 P.M. Mr. J. R. Hamblin and Mr. T. H. Winsor will read a paper on the Resolution of Gratings by the Astigmatic Eye, and Mr. O. Aves a paper on the Deviograph and Trial Frame.

HARWICH FORCE DINING CLUB.—This Club was established in 1924 for the purpose of reuniting all commissioned officers who served as such at Harwich at any time during the war, 1914–18. A dinner is held once a year, and all officers of the R.N.R., R.N.V.R., as well as the Royal Navy and Marines are eligible for membership. The dinner this year is to be held at the Hotel Metropole on Friday, Dec. 16th. Any officers desiring to become members should communicate with Lieut.-Commander H. Trevor Dawson, R.N., 6, Broadway, Westminster, S.W. 1.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual dinner will be held on Thursday, Nov. 17th. The guests will include Mr. Neville Chamberlain (Minister of Health) and Lord Eustace Percy (President of the Board of Education).

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL.—On Friday, Nov. 11th, at 4 P.M., Mr. Ernest B. Waggett will deliver the annual address, entitled On Observation.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society will be held at the Miller General Hospital, Greenwich, on Friday, Nov. 11th, at 8.45 P.M., when Dr. Edward Mapother will deliver an address on Coöperation by the Profession in the Treatment of Mental Disorder.

THE BRITISH SCIENCE GUILD.—The subject of the third annual Norman Lockyer lecture will be Scientific Ethics, and it will be given by Dean Inge on Monday, Nov. 21st, at 4 P.M., in the Goldsmiths' Hall, Foster-lane, London, E.C. Admission is free and tickets may be had from the Secretary of the Guild, 6, John-street, Adelphi, W.C. 2.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Monday, Nov. 7th, at 5 P.M., at the Medical Society, 11, Chandos-street, Cavendish-square, W., Sir StClair Thomson will deliver a lecture on Bleeding from the Nose and Throat. On Wednesday, Nov. 9th, at 12 noon, Mr. Greeves will give a special clinical demonstration at the Royal London Ophthalmic Hospital, and on the same day at 3 P.M. Sir William Willcox will give a special demonstration at St. Mary's Hospital. Mr. Cecil Rowntree will demonstrate on Thursday, Nov. 10th, at 3 P.M., at the Cancer Hospital. The lecture and demonstrations are open to members of the medical profession without fee. From Nov. 14th to 26th there will be a clinical course at St. Peter's Hospital, including a series of formal lectures on diseases of the urinary tract. From Nov. 14th to Dec. 3rd a course in surgery and gynæcology will be held at the Royal Waterloo Hospital, occupying the mornings and some afternoons. From Nov. 21st to Dec. 17th, at 5 P.M. daily, a series of clinical demonstrations upon selected cases will be given by the staff at the West End Hospital for Nervous Diseases, and from Nov. 21st, daily from 4.30 P.M. to 6 P.M., for two weeks, there will be a course for practitioners at the London Temperance Hospital. A course in proctology will be given at St. Mark's Hospital from Nov. 28th to Dec. 3rd. Copies of all syllabuses are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1, and will be sent regularly to those who wish to receive them. Specimen copies of the *Post-Graduate Medical Journal* will be sent on request.

JOINT TUBERCULOSIS COUNCIL.—At a meeting of the Council held at 1, Upper Montagu-street, London, W.C., on Oct. 22nd, attention was called to the restriction placed on tuberculosis schemes by the 1912 Act which aimed at the treatment of patients rather than the prevention of disease. A resolution sent up by the Society of Medical Superintendents and the Tuberculosis Society to the following effect was endorsed :—

> This meeting desires to draw the attention of the Ministry of Health to the grave difficulties in carrying out the scheme of the departmental committee on tuberculosis owing to the restrictions placed on the treatment of debilitated children who may be suffering from tuberculosis, by the necessity of waiting for the notifiable stage to be reached before action can be taken under the present tuberculosis scheme.

The Council considered that if there was a reasonable probability of tuberculosis in childhood the lack of precision in diagnosis and the sequential absence of notification should not necessarily hinder treatment in a suitable institution.—Officers for 1928 were elected as follows : Sir Henry Gauvain, chairman, Dr. Lissant Cox, vice-chairman, Dr. James Watt, treasurer, and Dr. E. Ward, Secretary.

Post-graduate Course in Radiology.—The Council is arranging a post-graduate course on radiology in tuberculosis and diseases of the lungs, to be held at the City of London Hospital (Victoria Park, E.) from Monday, Nov. 21st, to Saturday, Nov. 26th. Each morning there will be demonstrations of radiograms or museum specimens by members of the hospital staff, with further lectures or demonstrations in the afternoon. The radiograms will be displayed during the day so that members of the class may study them at their leisure. The fee is 3 guineas, and an application has been made to the Ministry of Health to allow the course to rank for grant. Application should be addressed to the hon. secretary, Post-graduate Courses, Joint Tuberculosis Council, at the Larches, Farnham Royal, Bucks.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—A general meeting of this association will be held at 11, Chan street, Cavendish-square, London, W., on Friday, Nov. 1 at 5 P.M. (tea 4.30 P.M.). Mr. W. Rowley Bristow will a paper on the Commoner Disabilities of Bones and Jo in Adolescence.

CHADWICK PUBLIC LECTURES.—On Thurs Nov. 10th, and Tuesday, Nov. 22nd, at 8.15 P.M., at Lecture Hall of the Royal Society of Arts, John-str Adelphi, London, Major Harry Barnes will give two lect on the History of Housing. The first will deal with period before 1885.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Herbert E. West, the deputy chairman, has been ele chairman in succession to the Earl of Denbigh, who rece resigned. Mr. West has been associated with the hos for many years and is chairman of Prince Henry's Sp Committee which is raising money for extensions.

LEAGUE OF RED CROSS SOCIETIES.—The ann meeting of the Council of the International Union aga Tuberculosis was held in Paris on Sept. 28th. Ten coun sent delegates—namely, Austria, Belgium, France, Germ Great Britain, Italy, Monaco, Norway, Poland, and Swit land. Finland and Bulgaria have now joined the Un which includes 34 countries. The sixth conference wil held at Rome in September, 1928.

SMOKE INSPECTION.—The Ministry of Health Circular 759 suggested that the officials responsible for abatement of smoke nuisances should be specially quali and that there should be special courses of training for th With this end in view, the Royal Sanitary Insti 90, Buckingham Palace-road, London, S.W., has arra a course of ten lectures beginning to-day (Nov. 4th) to a candidates preparing for the examinations of the Insti qualifying for the post of smoke inspector. The lect cover a wide field, and include, amongst other subjects, laws and by-laws relating to smoke ; the general princi underlying the production and transmission of heat ; f furnaces, and chimneys ; the principles and practic stoking ; the nature and composition of smoke ; anc prevention in boilers, furnaces, and domestic fires. course also includes visits to various works and institut where demonstrations illustrating the management working of different types of furnaces will be given. Alth primarily intended for smoke inspectors the lectures open to others.

ST. THOMAS'S HOSPITAL DINNER.—The an dinner on Oct. 28th was the first to be held in St. Thom House, opposite the hospital. Sir Charles Ballance, presided, referred to the different conditions of 50 y ago, and spoke appreciatively of Mr. le Gros Clark, William Macormac, and Dr. Charles Murchison, to w he owed a special debt. Reviewing the events of the y he mentioned the trouble to which Dr. Percy Smith been put in the courts to defend his professional righte ness and personal honour, and on behalf of those pre offered to Dr. Smith their sincere and affectionate sympa Sir Arthur Stanley, the treasurer, said that St. Thom House was proving very popular under the wardenshi Dr. L. B. Maxwell. He hoped that old students of hospital would look on it as their club in London. Cuthbert Wallace spoke of the loss which the hospital sustained by the death of Mr. J. E. Adams. Among o old students who had died during the year were Sir B Donkin, Dr. J. R. Leeson, and Dr. J. H. Tonking, of C borne, who had been the surgical father of Devon Cornwall for many years. As new members of the sta welcomed Mr. Max Page, Mr. Robinson, and Dr. Po The entry of new students this year had been the la for a considerable period. After mention of the well-deserved honours recently conferred on Sir Charles Ma and Sir Farquhar Buzzard, Sir Cuthbert Wallace e with a personal tribute to Sir Charles Ballance, spea of the way in which he had always helped younger and of his patriotism and loyalty. Mr. Percy Sa proposed the health of the guests in an amusing sp Sir Arthur Keith, who responded, said that if 40 y ago he had been shown St. Thomas's House, and had told it was a home of medical students, he would h thought himself in another world. There had bee revolution in the social circumstances of medicine there was no doubt about it, they were getting much extravagant. He had first come to St. Thomas's visitor on arriving in London, and from those who rece him so kindly had learnt a lesson which he would n forget—that a man should never let business inte with courtesy to strangers.

Messrs. J. and A. Churchill, medical and scientific blishers since 1825, have transferred their premises to Gloucester-place, Portman-square, W.1.

PRINCE OF WALES'S HOSPITAL.—The annual dinner the Reunion Association will be held at the Trocadero staurant, Piccadilly Circus, London, on Friday, Nov. 11th, 8 for 8.15 P.M., Mr. Edward Gillespie in the chair. e Secretary of the Association is Dr. J. Browning xander, 42, Harley-street, W. 1.

INCORPORATED GLASGOW DENTAL HOSPITAL.—It been decided to erect a new building for this institution a cost of £90,000 upon a site in Renfrew-street. At a blic meeting to consider the situation of the hospital, A. S. M. Macgregor, the medical officer of health, stated t the whole of the work was carried on "under conions of gross overcrowding." The waiting-room is small ill-ventilated, and when it is full patients have to wait the stairs and in the street. In the main operating room dental chairs are so closely packed that there is scarcely m to pass between them; the mechanical section is badly rcrowded, and the quarters of the dental school are anitary.

INTERNATIONAL CONTINUATION COURSE IN PUBLIC ALTH.—Under the auspices of the Health Organisation the League of Nations an International Continuation rse in Public Health is being held at the house of the iety of Medical Officers of Health from Nov. 3rd until . 15th. Participants nominated by the League are nding from the Continent and the British Dominions. ew tickets for the course have been offered to medical cers of health, for the use of members of their staffs o may wish to attend the lectures in which they are ecially interested. Any places remaining will be allotted rder of application to those who apply for admission ls to the Executive Secretary, 1, Upper Montagueet, Russell-square, W.C. 1. The lecturers from abroad ude Dr. A. Foramittie (Vienna), Prof. B. Nocht mburg), Dr. Debré (Paris), Prof. G. Y. Giglioli (Florence), f. F. Neufeld (Berlin), Prof. Clemens Pirquet (Vienna), Haven Emerson (New York), and Dr. M. Taute (Berlin), F. G. Boudreau and Dr. M. K. Stouman, of the Health tion of the League of Nations, will also give papers.

he opening address was to be delivered by Sir George rman, and other addresses during the course will be en by Sir George Buchanan and other senior medical ers of the Ministry of Health, Sir W. Hamer, Prof. Carl wning, Prof. W. W. C. Topley, Surgeon Commander S. F. iley, Prof. E. P. Cathcart, Sir Henry Gauvain, Dr. ward Mapother, Dr. Andrew Balfour, Prof. H. R. Kenrd, Dr. R. A. Lyster, Dr. J. J. Buchan, Dr. Charles ter, Dr. T. H. C. Stevenson, Dr. G. F. Buchan, Dr. C. J. mas, Dr. W. M. Willoughby, Dr. F. C. Shrubsall, Dr. Allen Daley, and Lieut.-Colonel F. E. Fremantle, M.P.

Medical Diary.

nformation to be included in this column should reach us proper form on Tuesday, and cannot appear if it reaches ater than the first post on Wednesday morning.

SOCIETIES.

YAL INSTITUTION, Albemarle-street, W.
TUESDAY, Nov. 8th.—5.15 P.M., Sir J. H. Parsons: Light and Sight.

YAL SOCIETY OF MEDICINE, 1, Wimpole-steet, W.
TUESDAY, Nov. 8th.—5 P.M., THERAPEUTICS. Paper: Dr. R. D. Lawrence: Studies of Unusual Diabetics: (*a*) An Insulin Resistant Case; (*b*) Recovery From (?) Pituitary Diabetes after Pregnancy. Dr. F. Parkes Weber: A Note on Artificial Cerebral Congestion against Sea-sickness. Dr. J. H. Gaddum: A Comparison of Thyroxin with some other Iodine Derivatives. Other papers will be read. 8.30 P.M., PSYCHIATRY. Presidental Address: Dr. R. L. Langdon-Down: Psychiatry and the Report of the Royal Commission.
WEDNESDAY.—5.30 P.M., SURGERY: SUBSECTION OF PROCTOLOGY. Discussion on the Treatment of Cancer of the Rectum by Radium, to be opened by Sir Charles Gordon-Watson. Those desiring to take part in the discussion should send their names to the Hon. Secretary.
THURSDAY.—8 P.M., NEUROLOGY. Clinical Meeting at the Hospital for Epilepsy and Paralysis, Maida Vale, W. 9.
FRIDAY.—5.30 P.M., CLINICAL. (Cases at 5 P.M.) Mr. C. P. G. Wakeley: Case of Fibro-cystic Disease of the Femora. Dr. Dorothy Hare: Case of Erythromelalgia. Dr. Donald Hunter: Case of Co-arctation of the Aorta. Dr. Douglas Firth: Case of Gumma of Liver with Splenomegaly. Mr. P. H. Mitchiner: Tumour of Trapezius. Dr. Adolphe Abrahams: Case of Primary Arterial Fibrosis. Dr. B. T. Parsons-Smith: Case of Intrathoracic Tumour. Other cases will be shown. 8.30 P.M., OPHTHALMOLOGY. (Cases at 8 P.M.) Cases: Mr. A. C. Hudson: A Case of Congenital Dislocation of Both Lenses Treated by Iridotomy. Mr. P. G. Doyne: Two Cases of Macular Degeneration. Communications, &c.: Mr. O. Gayer Morgan and Dr. F. D. Howitt: The Application of Heat by Diathermy in Iridocyclitis. Dr. P. H. Adams: Two Cases of Congenital Cataract with Spontaneous Absorption of the Lens. Mr. Ernest Clarke and Dr. Rayner Batten: Drawings illustrating Toxic Hæmorrhagic Retinitis.

HUNTERIAN SOCIETY.
MONDAY, Nov. 7th.—9 P.M. (in the Cutlers' Hall, Warwick-lane, E.C.). Discussion on the Legal Perils of the Doctor, in which Earl Russell, Mr. Rayner Goddard, Dr. James Neal, Sir Herbert Waterhouse, and Dr. Temple Grey will take part.

BIOCHEMICAL SOCIETY.
MONDAY, Nov. 7th.—5 P.M. (in the National Institute for Medical Research, Hampstead, N.W.). Communications: M. Stephenson: On a Cell-free Dehydrogenase Obtained from Bacteria. G. A. Harrison: The Cause of Andrewes' Diazo Test for Uræmia. A. Harden and F. R. Henley: The Equation of Alcoholic Fermentation. W. V. Thorpe: Presence of Histamine in Tissue Extracts. O. Rosenheim: Note on the Fluorescence of Ergosterol and its Cause. M. G. Eggleton and P. Eggleton: A Few Observations Concerning Phosphagen. Demonstrations: J. T. Irving: A Simple Shaker for Light Objects. O. Rosenheim and E. Schuster: A New Colorimeter based on Lovibond's Colour System.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.
TUESDAY, Nov. 8th.—5 P.M., Dr. Herbert Spencer: The History of British Midwifery from 1650 to 1800. (First FitzPatrick Lecture.)
THURSDAY, Nov. 10th.—5 P.M. (Second FitzPatrick Lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
THURSDAY, Nov. 10th.—5 P.M., Sir Cuthbert Wallace: Enlarged Prostate—A Review. (Bradshaw Lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Nov. 7th, to SATURDAY, Nov. 12th.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society, 11, Chandos-street, Cavendish-square, W., on Mon., at 5 P.M., Sir StClair Thomson: Bleeding from the Nose and Throat.—ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C. Special demonstration on Wed., at noon, by Mr. Greeves.—ST. MARY'S HOSPITAL, Paddington, W. Wed., at 3 P.M., special demonstration by Sir William Willcox.—CANCER HOSPITAL, Fulham-road, S.W. Thurs., at 3 P.M., special demonstration by Mr. Cecil Rowntree. All the above are free to the medical profession.—BROMPTON HOSPITAL FOR DISEASES OF THE CHEST, Brompton, S.W. Special course for one week. Instruction in all departments.—HAMPSTEAD GENERAL HOSPITAL, Haverstock-hill, N.W. General practitioners' course—second week—4.30 to 6 P.M. daily. Further information from the Secretary, Mayfair 2236.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Nov. 7th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
There will also be a special demonstration of dermatological cases at 2 P.M. on Wednesday, and of surgical cases on Friday, at 2 P.M., by Dr. W. Jenkins Oliver and Mr. E. Gillespie respectively.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.
MONDAY, Nov. 7th.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Donald Armour: Operations. 2 P.M., Dr. Ironside: Medical Out-patients.
TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 2 P.M., Mr. Addison: Operations. 4.30 P.M., Dr. Owen: The Heart in Childhood.
WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
THURSDAY.—11 A.M., Resident Assistant Surgeon: Ward Demonstration. 2 P.M., Mr. Bishop Harman: Eye Department. 3 P.M., Sir Henry Simson: Gynæcological Ward Visit.
FRIDAY.—11 A.M., Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.
Daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M., In- and Out-patients, Operations, Special Departments.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.
WEDNESDAY, Nov. 9th.—4 P.M., Mr. V. Z. Cope: Clinical Demonstration of Surgical Cases.

ROYAL NORTHERN HOSPITAL, Holloway, N.: POST-GRADUATE COURSE.
TUESDAY, Nov. 8th.—3.15 P.M., Dr. Malcolm Donaldson: Antenatal Care.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Nov. 10th.—4 P.M., Dr. W. W. Payne: The Value of Blood-sugar Estimation in Diagnosis and Treatment.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Nov. 8th.—5 P.M., Dr. H. MacCormac: Diseases due to Animal Parasites.
THURSDAY.—5 P.M., Dr. W. J. O'Donovan: Occupational Dermatitis.

ANCOATS HOSPITAL (Mill-street, Manchester) POST-GRADUATE LECTURES.
THURSDAY, Nov. 10th.—4.15 P.M. (tea at 3.45 P.M.), Mr. E. E. Hughes: Some Remarks on Gall-stones.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Nov. 8th.—4.15 P.M., Mr. F. G. Wrigley: Acute Otitis Media.
FRIDAY.—4.15 P.M., Mr. J. Spalding: The Education of the Deaf Child and the Work Done in the Manchester Schools.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Nov. 11th.—3.30 P.M., Mr. Garrick Wilson: Surgical Cases.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Nov. 8th.—4 P.M., Prof. J. Charteris: Pharmacological Principles in Relation to Common Gastro-intestinal Ailments. Discussion to be opened by Dr. W. F. Mair.
FRIDAY.—4 P.M., Case reading and discussion, in which all medical practitioners are invited to take part.

PEOPLE'S LEAGUE OF HEALTH.
THURSDAY, Nov. 10th.—6 P.M. (at 11, Chandos-street, Cavendish-square, W.), Dr. H. Gardiner-Hill: Internal Secretions as Factors in Nutrition.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Nov. 9th.—4 P.M., Lt.-Col. F. E. Fremantle, M.P.: The Present Situation in Regard to Housing.

CHADWICK PUBLIC HEALTH LECTURES.
THURSDAY, Nov. 10th.—8.15 P.M. (at the Royal Society of Arts, John-street, Adelphi, W.C.), Maj. Harry Barnes, F.R.I.B.A.: Housing before 1885 (first of two lectures on History of Housing).

Appointments.

King's College Hospital and Medical School: WILLIAMS, R. P., M.D. Lond., D.P.H. Oxf., Lecturer in Hygiene; LIVINGSTONE, J. L., M.D., M.R.C.P., Demonstrator in Pathology; EAST, C. F. T., M.D. Oxf., F.R.C.P. Lond., Medical Tutor; EDWARDS, H. C., M.B. Lond., F.R.C.S. Eng., Surgical Tutor; SAUNDERS, R. M., M.B., Ch.B. Edin., Obstetrical Tutor and Obstetric Registrar; LUCAS, H. A., M.R.C.S., L.R.C.P. Lond., Pathological Tutor; BICKERTON, J. M., M.B. Oxf., F.R.C.S. Eng., Ophthalmic Tutor; NEWMAN, C. E., M.B., B.Ch., M.R.C.P. Lond., Medical Registrar; BELL, J. G. Y., M.B., B.S. Lond., Surgical Registrar; WOOD, H. L. C., M.B., B.S., RUTHERFORD, R., M.R.C.S., L.R.C.P. Lond., COGSWELL, A. P., M.R.C.S., L.R.C.P. Lond., DALZELL, A. C., M.B., B.S., BATTEN, G., B.M., B.Ch., HOLLINS, A. S., M.R.C.S., L.R.C.P. Lond., BUTLER, E. N., B.M., B.Ch., GOLDBY, F., M.R.C.S., L.R.C.P. Lond., BOCKETT, E. J. C., M.R.C.S., L.R.C.P. Lond., KENDALL, A. W., M.R.C.S., L.R.C.P. Lond., WAKELEY, L. S. P., M.R.C.S., L.R.C.P. Lond., NEWMAN, J. L., M.R.C.S., L.R.C.P. Lond., DAUNCEY, K. E. D., M.R.C.S., L.R.C.P. Lond., LIVINGSTONE, G. H., M.R.C.S., L.R.C.P. Lond., and BOWIE, E. D., M.B., B.S., Resident Medical officers; MACHUGH, M. A. C., M.R.C.S., L.R.C.P. Lond., Junior House Anæsthetist; CUMINGS, J. N., M.R.C.S., L.R.C.P. Lond., HUMPHREYS-OWEN, I. R., M.R.C.S., L.R.C.P. Lond., MAY, K. S., M.R.C.S., L.R.C.P. Lond., and MACMYN, D. J., M.R.C.S., L.R.C.P. Lond., Assistant Casualty Officers.

Certifying Surgeons under the Factory and Workshop Acts: BROWN, A. C., M.D., Ch.B. Edin. (Ripon District of the County of York, West Riding); MORRIS, J. W., L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glasg. (Festiniog District of the County of Merioneth); and SOMERVILLE, I. F., M.B., Ch.B. Glasg. (Beith District of the County of Ayr).

Vacancies.

For further information refer to the advertisement columns.

Birmingham City Education Committee.—Asst. Sch. M.O. £600.
Birmingham and Midland Ear and Throat Hospital.—Surg. and Asst. Surg.
Bournemouth, County Borough.—M.O.H. £1000.
Bristol General Hospital.—Hon. Surg. Reg. Also Hon. Asst. P.
Burton-on-Trent, Bretby Hall Orthopædic Hospital.—Res. M.O. £450.
Buxton, Devonshire Hospital.—Bacteriologist. £400.
Cairo, Egypt, Girls' Schools under the Ministry of Education.—Asst. Med. Inspector. L.E.480.
Canterbury Borough Mental Hospital.—Asst. M.O. £350.
Cardiff University College of South Wales and Monmouthshire.—Professor of Pathology and Bacteriology. £1500.
Central London Throat, Nose, and Ear Hospital.—Second Re H.S. At rate of £75.
Croydon County Borough.—M.O.H. £1300.
Dreadnought Hospital, Greenwich.—Med. Supt. £300.
Durham County and Sunderland Eye Infirmary.—Locum.
Ealing Borough.—Asst. M.O.H. £600.
East London Hospital for Children and Dispensary for Wome Shadwell, E.—Phys. Also Asst. Phys.
Elizabeth Garrett Anderson Hospital, 144, Euston-road, N.W.—H.P., Obstet. Asst., 2 H.S.'s. Each at rate of £50. Al Clin. Assts.
Hampstead General and North-West London Hospital. Haverstoc hill, N.W.—H.S. At rate of £100.
Ipswich, East Suffolk Administrative County of.—Asst. Coun M.O.H. £600.
Italian Hospital, Queen-square, W.C.—Hon. Surg. to Throa Nose, and Ear Dept. Also Asst. Anæsthetist.
Kingston-on-Thames, Surrey County Mental Hospitals.—Thi Asst. M.O. £300.
Leeds, Tuberculosis Sanatorium, Killingbeck.—Asst. Res. M. £250.
Lewisham, Metropolitan Borough of.—M.O.H. £1100.
Liverpool Maternity Hospital, Oxford-street.—H.S. At rate of £
London Jewish Hospital, Stepney Green, E.—Res. M.O. A Jun. Res. M.O. At rate of £150 and £100 respectively.
Middlesex Hospital, W.—Res. M.O. £400. Also Asst. Rad logist. £150.
Middlesex Hospital Medical School.—Two Surgical and Medical Registrar. Each £300.
New Zealand Research Laboratories.—Dairy Research Bacter logist. £850.
Nigeria.—Four M.O.'s for Tsetse Fly Investigation. Each £6
North Middlesex Hospital, Edmonton, N.—Visiting Throat Su Three guineas per session.
Norwich, Norfolk and Norwich Hospital.—H.S. £120.
Poplar Hospital for Accidents, East India Dock-road, E.—Secc Res. O. £175.
Royal Free Hospital, Gray's Inn-road, W.C.—Two Assts. M.O. in charge of V.D. Dept. Each £500.
Royal Northern Hospital, Holloway, N.—Asst. Radiolog £140.
St. Albans and Mid-Herts Hospital and Dispensary.—Res. M. £150.
St. John's Hospital, Lewisham, S.E.—Gynæcologist to O patients.
St. Mary Abbots Hospital, Kensington.—Med. Sec. and Regist £300. Also two Asst. M.O.'s. Each £250.
Sierra Leone, School Laboratory, Freetown.—Two Research As Each £600.
Southampton, Royal South Hants and Southampton Hospital Cas. O. £120.
Surrey County Council.—Asst. M.O.'s. Each £600.
Swansea Hospital.—H.S. to Ophth. and Aural Depts. £150–£2
Warwick County Mental Hospital, Hatton.—Asst. M.O. £30
Westminster Hospital, Broad Sanctuary, S.W.—Asst. P.
Worcester General Infirmary.—Jun. Res. M.O. £120.

The Chief Inspector of Factories announces a vacant appo ment for a Certifying Factory Surgeon at Lydbr (Gloucestershire).

Births, Marriages, and Death

BIRTHS.

HOME.—On Oct. 21st, at Grosvenor-street, Edinburgh, the of Dr. Bruce F. Home, West African Medical Service, daughter.

NEAME.—On Oct. 25th, at Greenheyes, Buckhurst Hill, wife of C. Stanley Neame, L.D.S. R.C.S. Eng., of a son.

MARRIAGES.

LOUGHNANE—KEATINGE.—On Oct. 29th, at the Brom Oratory, Farquhar MacGillivray Loughnane, F.R. Welbeck-street, to Blanca Keatinge, of Nottingh place, W.

STRACHAN—FORSYTH.—On Oct. 26th, at St. John's Episc Church, Dumfries, Frederick James Strachan, M.B., B.S., to Olga Marie, youngest daughter of the William Forsyth, Kilmarnock.

SUMMERS—BAIRD.—On Oct. 27th, at St. Peter's Ch Burnham, Bucks, by Rev. Percy Nott, M.A., Max Hamilton Summers, M.R.C.S., L.R.C.P., to Evelyn Eliza Baird, M.A., M.B., Ch.B.

DEATHS.

CHOLMELEY.—On Sunday, Oct. 30th, Henry Patrick Cholm M.D., at Forest Edge, Forest Row, Sussex, aged 68.

DAY.—On Oct. 27th, at Harlow, Essex, Thomas Montagu M.R.C.S., L.R.C.P.

EVANS.—On Oct. 25th, at Glanfraed, Brundall, Norfolk, H William Evans, *M.C.*, M.D. Lond.

WALSH.—On Oct. 26th, at Thelsford Farm, Wellesbourne, Warwick, F. Newton Walsh, B.S., M.R.C.S., L.R. Lond., of Douglas-road, Handsworth, Staffs.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notic Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

ARTIFICIAL DEFORMATION OF THE SKULL:

A SUGGESTION AS TO THE ORIGIN OF THE CUSTOM.

BY WARREN R. DAWSON, F.S.A. SCOT.

THE head of the Egyptian King Amenophis IV. (c. 1375–50 B.C. Eighteenth Dynasty), who is usually known by e name he assumed after his great religious revolution Akhenaten—is always represented on his monuments as ving a peculiarly elongated form, whilst the rest of his dy is feminine in contour. As one of the results of his formation, Egyptian art during Akhenaten's reign under- nt great changes, and the singular bodily form of the ng as portrayed on his monuments has always been pposed to be no more than one of the novel conventions the new art. In 1907 a tomb was discovered and nounced as that of Queen Tiy, Akhenaten's mother. In e tomb the remains of a mummy were found, but owing the penetration of moisture into the chamber, the soft rts had entirely decayed leaving nothing but the skeleton. hen these bones were examined by Prof. Elliot Smith he nd them to be those, not of an elderly woman, but of oung man. Archæological evidence was soon forthcoming show that the tomb had been wrongly identified as that Queen Tiy, and no doubt remained that the burial was lly that of Akhenaten himself.

The skeleton proved to be one of exceptional interest, d a detailed description of it was published by Prof. liot Smith in his monograph, *The Royal Mummies* p. 51–57), in 1912. He came to the conclusion that the skull nibited signs of hydrocephalus, a view that was confirmed Prof. A. R. Ferguson, who pronounced the evidence of drocephalus to be quite unmistakable. Akhenaten had ner pathological peculiarities, and it now seems very obable that he was a case of the syndrome described by hlich in 1900, now known as dystrophia adiposogenitalis, h which hydrocephalus is often associated.[1]

Now it is a very curious fact that the infant daughters this King (he had no sons)[2] are always represented on ntemporary monuments with heads of a very peculiar pe, and, as in the case of Akhenaten himself, this had herto been held to be no more than a convention arising of the novel artistic concepts which came into vogue at time. In 1924 Prof. Elliot Smith expressed the view t the childrens' heads might have been subjected to the cess of artificial deformation.[3] At the time this suggestn was advanced he was not aware that the material for ving the mystery was already in existence, for in 1918 George Sobhy, of Cairo, published photographs and a cription of the head of a female mummy from Tell el arna (Akhenaten's capital), and of the period of that gn.[4] When the flesh and resin had been removed and skull cleaned, its shape shows without any doubt that had been artificially deformed. Dr. Sobhy made a storation of the head and features from the measurements the skull, and the result exactly resembles the form of head in the portraits and statues of Akhenaten's ughters.

There is no evidence to prove whether or not this skull longed to a member of Akhenaten's family, but it does least prove that artificial deformation was being practised Egypt during his time, and suggests that the form of henaten's head, pathologically deformed by nature, y have been deliberately copied by artificial means in case of his daughters. Egypt at the time set the fashions ich were copied wherever her influence extended, and it extremely likely that such an innovation would have n imitated in Western Asia.

This point lends particular interest to the account given Hippocrates of the "Longheads" of Asia Minor. He inctly tells us that these people remodelled by hand heads of their children immediately after birth, and t they forced the skull to increase in length by the use bandages and suitable appliances.[5] Hippocrates goes on to say that this peculiar form of head, originally produced by art, became natural, and that long-headed parents had long-headed children. We need not, however, discuss this insistence upon the false supposition of the inheritance of acquired characters, as this does not now concern us, but we may note that he concludes by saying that the custom had become less frequent than formerly. This definite evidence of cranial deformation in Asia Minor before the fifth century B.C. is of great interest, especially as Hippocrates implies that it was an ancient custom already becoming obsolescent in his time.

In later times, as is well known, the custom of deforming the skull acquired a wide geographical distribution, and it is very significant that it occurs almost always in association with megalith-building, mummification, and various other singular customs and beliefs which follow the "heliolithic track" round the world. Cranial deformation has been recorded from various parts of Europe and Western Asia, from Malaya, Indonesia, Melanesia, Southern North America, Central America, and South America (where the mummies of Peru have provided numerous examples), and elsewhere.

The facts, therefore, seem very suggestive of the interpretation that the custom had its origin in Egypt in the fourteenth century B.C., during the reign of Akhenaten, and thence spread, with mummification and other practices of admitted Egyptian origin, till it encircled the world.

Cambridge University Medical Society Magazine, 1926, 37.

The suggestion has recently been made that Tutankhamen y have been the son of Akhenaten by a secondary wife, but re is as yet no evidence to prove this.

THE PATHOLOGY OF ELECTRIC SHOCK.

SINCE the first fatality from industrial electricity in 1879, there has been much research into the exact cause of death by electrocution, and it has been shown that artificial respiration is of vital importance as a means of treatment. Nearly every industry in which electricity is used now trains its employees in preventive measures and in first-aid, but the number of casualties continues to rise, partly because the known methods of resuscitation are not immediately applied. In an endeavour to reduce the mortality from these accidents, the Hydro-Electric Power Commission of Ontario initiated a research into the physiopathology of electric shock, under the direction of Prof. J. J. R. Macleod, of the University of Toronto, and an account of the inquiry appeared in the *Journal of Industrial Hygiene* for April.

It is well known that one of the important effects of electric shock is to throw the heart into fibrillation, and rabbits were selected for most of the experiments because their hearts are relatively difficult to affect in this way. The equipment allowed of any variation in the current, and of its accurate measurement. In the first group of 33 rabbits, alternating currents varying from 1000 to 2200 milliampères were sent from the occiput to a hind leg, since previous observers had noted that this path usually missed the heart but caused disturbances in the brain and spinal cord. Nine began to breathe again spontaneously, six were restored by artificial respiration, and 18 died. In nine of these 18, the heart stopped beating within one minute of the cessation of the current, and in the remainder it continued for periods varying from two to nine minutes. The investigator, Dr. R. W. I. Urquhart, concluded that the heart was injured in 45 per cent. of the cases, and that it is impossible to predict whether, when a current passes the length of the body, the heart will be affected or not. A second series of 36 animals was subjected to the passage of currents of 500 to 1600 milliampères between the upper nostril and the exposed occipito-atloid ligament, so that the vital centres of the brain would alone be involved. These animals were anæsthetised, but the "eye reflex" was obtained before the current was passed. In any case the evidence goes to show that anæsthesia has no protective value. The result in 18 cases was death from asphyxia, with no evidence of fibrillation or gross injury, and 18 others recommenced breathing spontaneously. There was a more or less definite borderline between fatal and non-fatal currents at 600 to 700 milliampères, but with a smaller electrode lesser currents were required to produce fatal apnœa. This was probably because of a concentration effect.

Another significant experiment showed that 25 out of 30 animals could be revived after a shock which was severe enough to kill if they had been left alone. The five that died had all suffered gross damage to the spinal cord or the medulla, and the occipito-atloid ligament had been badly charred. Prompt and efficient artificial respiration, says Dr. Urquhart, nearly always saved the animal if started within five or six minutes of the shock, but after a longer interval the damage to the heart was irremediable. It was found necessary to continue the artificial respiration for a long time after natural breathing appeared. In contradiction of the popular belief in "counter-shock" as a restorative measure, no kind of stimulation had any effect in hastening recovery, and it was impossible to detect any reflex effects even from faradic shocks of the central end of the sciatic nerve. In addition to graphical records of blood pressure, direct observation was maintained on the heart

through a window in the chest wall, and it was seen to be inhibited completely in rabbits and dogs, and almost completely in cats. That the inhibition is due to stimulation of the vagus centres was proved by its great reduction when the vagi were severed and its complete absence when they were controlled by atropine, which would paralyse the extravagal inhibitory fibres as well. Moreover, the current itself causes a complete block at the vagal nerve-centre, so that no stimulation of it affects the blood pressure. No relation could be made out between the severity of the shock and the appearance of capillary hæmorrhages in various parts of the brain, and Dr. Urquhart considers that they are probably due to the sudden great increase in blood pressure which follows the passage of the current. They occur in survivors as well as in the dead, and are probably, he says, not an important factor in death from electricity.

The result of the whole inquiry is to throw even more stress on the importance of artificial respiration, particularly by the prone pressure method, and to the necessity of beginning it immediately and continuing it until recovery or decisive evidence of death. The ordinary tests for death are invalidated by the block in the nerve-centres, and no pains should be spared until the body cools or rigor mortis sets in.

Prof. Stefan Jellinek, writing in the *Medizinische Klinik* for Sept. 23rd, states that most fatalities from electric shock are due to faulty restorational technique. No injury, he says, has ever been found post mortem that would account for death, and the immediate effects of the shock are purely functional. He is very strongly in favour of wider instruction in artificial restoration, and of the provision of fully equipped restoration centres at mines, works, and all places where electrical accidents are likely to occur. Severe symptoms at first give the best prognosis, and immediate death is as a rule merely apparent. He recommends conservative treatment. Operation on damaged parts of the body is, he says, contra-indicated for two reasons: one is that the extent of the injury does not become obvious for some weeks, and the other is that from the end of the first week the vessels rupture easily and the hæmorrhages are very troublesome to staunch. Nevertheless, there are two exceptions to this. An emergency lumbar puncture is indicated when the patient shows symptoms of pressure in the brain, which may occur some hours after the accident, and hæmorrhage of the larger vessels a month or so later may call for immediate ligation if the patient's life is to be saved.

According to Prof. Jellinek the micropathological changes, as observed in the skin at the site of an electrical lesion, are a compression of the horny layer into an homogeneous plaque, and an ironing-out of the underlying papillary processes. Occasionally fissures and hollows appear between the corneum and germinativum, but this is not invariable, and the surest sign that an electric current has passed is the coalescence into a star-shaped or rod-like structure of the basal cells in each group of the rete Malpighii. The lesion is not a burn, and none of the surrounding structures are altered. It heals without infiltration, suppuration, or pyrexia, but when tendons, joints, and large areas are involved there may be some aseptic necrosis, and it is presumably this change which accounts for the hæmorrhages which sometimes complicate recovery. Macroscopically the appearance of the skin, when anything is to be seen at all, is a greyish-white patch slightly hard to the fingers, often with an umbilicated notch or dimple.

AN ENGLISH-SPANISH MEDICAL DICTIONARY.

A CORRESPONDENT asks to have recommended to him a good English-Spanish medical dictionary, but it appears that there is no such work that is properly inclusive and completely trustworthy. Our correspondent may be advised to obtain the "Medical Pocket Dictionary in Eight Languages (including Spanish)." (Berlin: Urban and Schwarzenberg (obtainable in London from Messrs. Williams and Norgate, 14, Henrietta-street, Covent Garden, W.C. 2, at 22s. 6*d*.)). "Terminologia Medica Polyglotta (including Spanish)," by the late Dr. Theodore Maxwell in the year 1890 (London: J. and A. Churchill, 7, Great Marlborough-street, W. 1, 16*s*.), was a good book in its time, but is, we believe, now out of print; and, of course, was tabulated and concise only, without detailed explanations. It might be worth while to refer to Manuel Marin, publisher, 273 Provenza, Barcelona, Spain, who published under the editorship of Dr. Alfonso Arteaga Pereira in 1918 a full translation into Spanish of an English medical annual and must be acquainted therefore with the many terms in both languages (the annual was intended to be continued). Our correspondent might also inquire in the United States from the Secretary of the American Medical Association, 535, North Dearborn-street, Chicago. Some years ago the United States authorities, in connexion with their administration of Manila, published elaborate tables of diseases and causes of death in parallel columns, English and Spanish, which could serve as a dictionary perhaps for many terms.

PRESENTS AND "TIPS" IN NURSING HOMES.

To the Editor of THE LANCET.

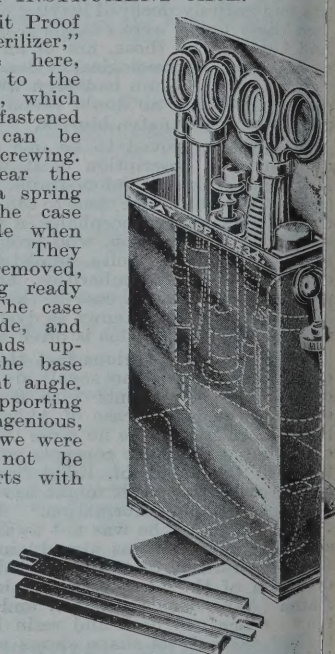
SIR,—For many middle-class patients the expenses [illegible] private nursing homes in our large towns are a very hea[vy] burden. But they are a burden which must be bor[ne] until more of our large hospitals establish pay wards. [illegible] some nursing homes (in what proportion I am unable [to] state) it is usual for patients, on leaving the home, to g[ive] presents to the nurses and "tips" to the servants. Su[ch] presents and tips are an additional heavy burden to ma[ny] middle-class patients, and except in special circumstan[ces] they should be unnecessary. To the writer it appears v[ery] desirable that this custom should not become gene[ral]. Medical men by doing what they can to oppose the cust[om] would help to diminish the expenses at nursing homes.

In one of the instances, in which I know all details, [the] presents to nurses and tips to servants, given by a pati[ent] (not wealthy) on leaving a London nursing home, reacl[ed] (at the suggestion of the matron) the sum of £13. Wealt[hy] patients should remember that by giving large presents a[nd] tips they are helping to establish a custom which is a hea[vy] burden for most patients. It is to be hoped that b[oth] general practitioners and consultants will, at least, do w[hat] they can to oppose the custom of giving presents to nurses.

I am, Sir, yours faithfully,

PHYSICIAN.

A POCKET INSTRUMENT CASE.



THE "Security Spirit Proof Emergency Pocket Sterilizer," which we illustrate here, should be of value to the practitioner. The lid, which is seen detached, is fastened by two bolts and can be removed without unscrewing. The plates which bear the instruments rest on a spring at the bottom of the case and therefore protrude when the lid is taken off. They can thus be easily removed, the instruments being ready for immediate use. The case is compact, well made, and watertight, and stands upright on a foot at the base which turns to a right angle. The method of supporting the instruments is ingenious, though in the model we were shown they could not be fixed to their supports with perfect security. The "Sterilizer," without instruments, is obtainable from the sole distributor, Charles F. Thackray, Park-street, Leeds, and 119, High Holborn, London, W.C. 1, at a cost of £1 2*s*. (postage extra).

The Longevity of Cricketers.—In our editorial comm[ent] last week on Dr. Bradford Hill's analysis of the duratio[n of] life in cricketers there was an obvious misprint. He was[, of] course, dealing with "cricketers of British nationality b[orn] *before* 1888."

Messrs. Baillière, Tindall and Cox, 7 and 8, Henrie[tta]-street, W.C., have issued a catalogue (dated October, 19[27]) of publications in medicine and allied sciences. The [first] section of the catalogue, which runs to 39 pages, deals [with] books of medicine, dentistry, or nursing published du[ring] the last ten years or so, the large majority quite recen[tly], the date of publication being given in each instance. T[here] are a few announcements of books in preparation. A convenient index of both subjects and authors precedes [the] catalogue.

Deaths from Infectious Disease in England and Wa[les] during the Week ended Oct. 1st, 1927.—These figures [were] inadvertently omitted in our issue of Oct. 15th. They should run as follows: In the aggregate of great tow[ns], including London, there was no death from small-[pox], 5 (1) from enteric fever, 9 (1) from measles, 2 (0) from sca[rlet] fever, 10 (0) from whooping-cough, 20 (4) from diphthe[ria], 94 (21) from diarrhœa and enteritis under two years, [and] 34 (5) from influenza. The figures in parentheses are t[hose] for London itself. The number of stillbirths regist[ered] during the week was 258 in the great towns, including 5[9 in] London.

An Address
ON
MEDICINE AND THE CHURCH.

ing the Annual Oration given before the York Medical Society on Oct. 19th, 1927,

SIR FARQUHAR BUZZARD, K.C.V.O.,
M.D. OXF., F.R.C.P. LOND.,
PHYSICIAN EXTRAORDINARY TO H.M. THE KING;
PHYSICIAN TO ST. THOMAS'S HOSPITAL.

THE word "indulgence" has various meanings, for ee at least of which I must advance a claim before ering upon the subject of my address.

ndulgence is a synonym for gratification, and how I fail to be not only highly gratified but deeply teful when I find my name added to your long and tinguished list of "Orators." In its more religious se an indulgence is equivalent to a grant of certain rties as a special favour, and I pray that this ulgence may be extended to one who has the erity to invade the ecclesiastical stronghold of the th and talk about the Church in the same breath as licine. Without indulgence in its third sense the ission of temporal punishment due to sins, I could dly expect to escape the fate of Dick Turpin, who ered the extreme penalty of the law in this city centuries ago for offences which at that time e deemed less heinous than those which I may e commit.

n return for these indulgences it is only equitable I should give you some of my reasons for choosing edicine and the Church" as a topic suitable for occasion. In the first place, I was instructed that audience would not be entirely medical and that remarks, therefore, should be intelligible to minds ttuned to the technical and none too beautiful guage of my profession. In the second place, I influenced by the belief that, in spite of all that been said and written about spiritual healing in nt years, there remain some considerations bearing hat and kindred subjects, of interest alike to the sician and the priest, which have not received all ventilation requisite for their health and sanity.

was encouraged to carry on with a delicate and cult task by the knowledge that York is not so far ant from Leeds that echoes of a recent controversy erning science and religion may not only have hed you, but have prepared an atmosphere ged with sympathetic interest.

is my firm belief that such open discussions, liable igh they are to become overheated, never fail to e behind in the minds of participators and of their ence some impressions which make for the better rstanding of divergent views. At any rate truth r took root in the stagnant soil of silence and ishes only after exposure to the light and heat of roversy.

MEDICINE IN ANTIQUITY.

he history of medicine is far too big a subject for to do more than touch upon now, but even a rficial study of it suffices to reveal its intimate ciations with the history not only of religions in ral, but with that of the Christian Church. It be helpful, therefore, to a consideration of the ionship of medicine to the Church at the present if I recall to memory the principal features of their eration and contention in the past. Perhaps the est example of conflict between the followers of healing art and divine authority is provided in hology by the legend of Æsculapius, who, it will emembered, not only healed the sick, but brought dead to life. This excess of zeal not unnaturally d the ire of Pluto, King of Hades, who, with on, was threatened with the prospect of joining anks of the unemployed. Zeus, on being appealed lew the tactless physician with a thunderbolt, but the gratitude of mankind was subsequently instrumental in raising the latter to the status of a god, in which capacity he has continued to exercise a beneficent and fatherly care over the fortunes of our profession.

To Egypt and to an era 3500 years before Christ we have to go back for the earliest indications of the art of medicine, which at that time was concerned only with treatment. It was practised by men who combined the offices of priest and physician and who regarded the invocation of blessings on their remedies as not the least important security for their success. They were frankly healers and professed little interest in, or knowledge of, the causation of disease.

The early records of both Indian and Persian medicine emphasise their close association with religion, and suggest that sickness and recovery therefrom were attributable to the influence respectively of hostile and friendly deities.

Hippocrates.

In Greece, however, were laid the real foundations of rational medicine, and it was left to Hippocrates, a direct descendant of Æsculapius, to develop from the prevailing methods and doctrines of his day a new outlook upon the origin and treatment of disease, which has caused him to be regarded as the greatest physician of antiquity. No longer content to take the path of least resistance in assigning to supernatural influences phenomena which appeared difficult to account for, he formulated a belief which to many minds, even at the present day, is sufficiently satisfying: "From God comes one disease as well as another; but nothing happens except in conformity with Nature." He may, perhaps, be looked upon as the pioneer of a doctrine which is perpetuated to-day in the shape of a spa practice. To him the conditions of health and sickness were determined by seasons, climates, waters, and soils, as well as by personal habits in such matters as food and exercise. His pathological conceptions were not so happy. Four humours of the body—blood, phlegm, yellow bile, and black bile—were, according to his theory, the primary seats of disease, and health varied in relation to disturbances in their proper combination and appropriate activities. Not his least claim to fame was his attitude of expectancy in regard to treatment. In fact his aversion to drastic remedies earned him the reproach of letting his patients die by doing nothing to keep them alive—a reproach which has lost some of its sting with the advance of knowledge!

The work of Hippocrates, showing as it did that the advance of medicine was based on anatomy, physiology, and the scientific investigation of patients, impressed its mark on succeeding generations. On the one hand, anatomy was studied assiduously and fruitfully, especially in the Greek school at Alexandria; on the other hand, physiology became the playground of theories, too numerous to refer to, and too fantastic to deserve the attention of any but historians.

Galen.

And so we come to Galen, born at Pergamus in A.D. 131, who was destined to influence the progress or, perhaps it would be more correct to say, the stagnation of medicine for from 12 to 15 centuries. As an expositor of the medical knowledge of his time, as an anatomist and skilled dissector of the bodies of lower animals, and as a practical physician his reputation must always stand pre-eminent. As a physiologist and pathologist his contributions were of less value, and his dogmatism in regard to these subjects, fostered by the atmosphere of infallibility which pervaded both medicine and the Church for so many centuries, was a standing menace to all progress during the whole of that time. It must be noted, however, that Galen's doctrine did not come into its full power until his writings, having been translated into Latin, began to be studied in the West, with the result that by the sixth or seventh century his name and authority began to dominate medicine and thereafter kept it in chains for another thousand years.

Early Relations of the Church and Medicine.

It is germane to the subject of my address that we should pause for a moment to compare the history of the Church with that of medicine during that period. From the close of the eighth century until the Reformation in the sixteenth the Church, including all adherents to the Christian faith, was dominated by Rome, and the Papal ascendancy was so complete, its authority so infallible, that all individual freedom of thought was abolished. In these ages there developed the immoderate expansion of the religious and social omnipotence of Christianity, manifesting itself in the temporary subordination of the Church to the State, in the suppression of all criticism, and in the abundance of monastic orders.

The stories of medicine and Galen run on somewhat parallel lines. From the early Middle Ages the religious orders were the custodians of the degenerate knowledge and practice of the healing art inherited from the later Roman authors until the curious mixture of ancient science with the black art, characteristic of monastic medicine, was superseded by the Hippocratico-Galenic revival. The latter doctrine survived until the medical reformation, which took place very little later than that of the Church and which is so closely associated with the name of Vesalius, the founder of modern anatomy, who was condemned by the Inquisition as a sorcerer, and with that of William Harvey, the father of modern physiology. But those who took part in the reformation of medicine were not only exposed to the persecution of the Church, but were bitterly opposed by the disciples of Galen, and Vesalius himself did not escape the hostility of the latter when he published his monumental work on human anatomy in 1543.

The Church during the Middle Ages exerted its influence to uphold the Galenic doctrine, which presented no inconsistencies with the Christian faith and which dogmatically provided an answer to every question. Comment was allowed and commentators abounded. Criticism, on the other hand, was looked upon as a species of heresy and critics shared the fate of religious heretics. Research and experiment were regarded as closely akin to sorcery and witchcraft.

But medicine owes the Church a debt of gratitude for the performance of at least two valuable functions during the dark years of its history. The monastic orders were responsible for preserving the ancient literature of our profession, which would otherwise have been lost, and they were pioneers in the establishment of hospitals which eventually formed the basis of many famous and productive medical schools.

Ecclesiastical Control of Education and Practice.

Enough, perhaps, has been said to indicate the intimacy which existed between medicine and the Church throughout the Middle Ages, but it is worth while bearing in mind the control exercised by the latter over the former in regard to education and practice. To quote Dr. Arnold Chaplin :—

> " In early times, before the foundation of the Universities, the art of Medicine was largely the province of the Church, but in 1131, the Council of Rheims prohibited the regular clergy from devoting their attention to physical compositions, and after this edict the regular clergy confined themselves to prescribing medicines. In 1139, the Council of the Lateran prohibited physicians from administering to the wants of the body before the spiritual needs of the patient had received attention . . . . In 1422 the first enactment concerning the practice of medicine appears upon the statute book. ' No one shall use the mysterie of fysyk, unless he hath studied it in some University and is at least a bachelor in the science. The Sheriff shall enquire whether any one practice in this country contrary to this regulation ; and if any one so practice he shall forfeit £40 and be imprisoned.' The Church, however, still continued to exercise some authority, for in a statute of 1511 it is stated that ' except for those graduating in Medicine at Oxford and Cambridge, all desiring to practise medicine or surgery in London and seven miles around must be approved, after examination, by the Bishop of London or the Dean of St. Paul's with, in the case of Physicians, the assistance of four doctors in physick, and, in the case of surgeons, of other expert persons of that faculty.' "

A New Attitude towards Research.

It is interesting, too, to compare the writings scientific pioneers in the sixteenth and seventeen centuries with those of modern medical write and to trace the gradual development of a ne attitude towards research. Thus the secrets Nature came no longer to be regarded as sacred a knowable only to the Almighty, when difficulti were encountered in the attempt to unravel the There arose, on the contrary, a spirit of inqui undeterred by obstacles and no longer trammell by the belief that the search after knowledge w incompatible with the Christian faith. Let me quo two passages, one from Vesalius and the other fr Harvey, the latter written about 50 or 60 years aft the former.

Vesalius (1514–1564) : " The septum of the Ventric abounds on both sides with little pits impressed in it. these pits, none, so far at least as can be perceived by senses, penetrate through from the right to the left ventri so that we are driven to wonder at the handiwork of Almighty, by means of which the blood sweats from right into the left ventricle, through passages which esc human vision."

Harvey (1578–1657) : " When I first gave my mind vivisections, as a means of discovering the motions and u of the heart, and sought to discover these from act inspection and not from the writings of others, I found task so truly arduous, so full of difficulties, that I almost tempted to think, with Frascatorius, that the mot of the heart was only to be comprehended by God. length, and by using greater and daily diligence, hav frequent recourse to vivisections, employing a variety animals for the purpose, and collecting numerous obser tions, I thought that I had attained the truth."

At the time when Harvey was engaged on his li work, the result of which was to deliver from darkn into the light of truth the secret of the circulat of the blood, the Church found it desirable to for the clergy to attempt to cast out devils by fast and prayer, except by special licence from the bish

Separation of Medicine and the Church.

So much for the history of medicine up to the t of Harvey. The tercentenary of the publication his " De Motu Cordis," the monograph giving to world his great discovery, is to be celebrated i befitting manner next year.

Since his time the science of medicine has stea progressed, partly as the result of untiring resea at the bedside, in the post-mortem room, and laboratories, and partly as the result of the ra development of such ancillary sciences as those physiology, anatomy, chemistry, physics, biolo and bacteriology. Progress at first was slow, hampe by tradition, by prejudice, and by the very hur mistake of regarding hypotheses as final conclus instead of using them as a basis for research. In last 100 years the wheels of progress have mo much more rapidly, and, as I propose to show, conception of medicine as a profession has comple altered since the days when the physician-pries Egypt essayed blindly to cure the sick with a mix of blessings and herbs. But before attempting describe the science of medicine as it stands to- let us survey dispassionately the story of its evolu which I have outlined so briefly. The results of survey, whatever be their explanation, are clear incontestable. For more than a thousand y during which the Church shared the practice of medi with physicians, and dominated its methods, du which she was at the height of her spiritual po and during which millions of the sick and suffe must have passed through her hands, there wa material advance in the knowledge of disease its cure, or of its prevention. Moreover, from records of those centuries in which the Church every facility and every opportunity of proving gifts, there has survived no evidence in suppor the claim that spiritual healing of organic dis is a practical proposition, or that spiritual he differed, either in its essence or its efficacy, from c methods based on suggestion and faith, religiou otherwise.

On the other hand, the last two or three hundred ears have witnessed a gradual separation of the aths of medicine and of the Church, and synchronous ith that process the advances of medicine in regard the diagnosis, treatment, and prevention of disease ve only been equalled by the remarkable progress ade in other branches of science which threw off e fetters of the Church about the time of the eformation.

PRESENT CLAIMS OF THE MEDICAL PROFESSION.

And now let me embark on a difficult task, one ich calls for performance, and one which is a cessary and pertinent adjunct to what has preceded and to what is to follow it in my address to-day. is my purpose to answer as briefly and yet as rthfully as I can, the questions: What is the sition, and what are the claims of the medical ofession to-day?

Looking back, it is undeniable that during more an 5000 years the claim of those who practised dicine was to cure their patients of disease. It s not only their claim; it was what they were paid and what was expected of them, although it must admitted the claim has, as often as not, failed to be ostantiated. But in the course of the last century two we have gradually realised that no claim of that id can be maintained by us until we have mastered elements of knowledge regarding the causation and ognition of disease. Our conception of diseases has ered. They are no longer evil spirits to be exorcised; y are no longer distinct entities, and they hardly erve, except for convenience sake, the honour of a ne. An illness is the outward manifestation of a tle taking place between man and one or more of enemies, the adequate study of which entails a owledge of the patient, his heredity, his past and sent environment, his reactions, and powers of ack and resistance, as well as a close acquaintance h the properties and natural history of the enemy. recognise that, although we have learned much ut these combatants, our knowledge is still nentary, full of gaps, and often inapplicable as a or in deciding the issue of the conflict.

What is our position then? We place what knowge we possess at the disposal of our patient, we are dy to advise to the best of our ability in regard to disposition and conservation of his forces, we will g to his aid any auxiliary troops on which we have on to depend, and we will supervise and regulate tactics employed; but we make no claim to cure, er during the heat of battle or after victory has n won, should that be the result.

is inevitable, and perhaps fortunate, that in e of this modest standpoint, we are not infrequently lited with a success to which we have contributed le. It is inevitable, too, that our contributions to ccess are often valued in inverse proportion to their worth.

n the other hand, we, and we only, are in a position easure the part played by various factors leading uccess or failure in any case of illness under our , a task often of extreme difficulty to the most ned and experienced of physicians, and quite ossible to the patient or his untrained relatives friends. While we make no claim to a "gift of ing," it is not always beyond our powers to aise correctly the relative value of contributions e by nature, by drugs, or by suggestion towards a urable result.

PREVENTION.

n account of the position of the medical profession ay would be incomplete without a brief reference hat is known as its preventive side. With our easing knowledge of the causes of illness, and our gnition of the possibility that there may be ases concerning which complete understanding is inable, and which may yet remain unamenable to form of treatment, it is not unnatural that our est has turned, and tends every day to turn more, ards the question of their prevention. Preventive icine is still in its infancy, but as it matures it must inevitably call for intelligent, educated coöperation from the public, the State, and the Church.

The scope of our professional activity has extended, during the period laid under review, from an art concerned with healing to a science devoted in the first place to revealing the secrets of health and disease, and in the second place to utilising the knowledge thus gained for the relief of suffering, physical and mental.

PSYCHOLOGICAL MEDICINE.

Mental suffering is the subject which must next engage our attention, and I propose to use the term in its widest sense. The scientific study of mental processes and, in particular, the study of the brain as the organ of mind, lagged behind that of other parts of the body for a long time, but of recent years has so quickened its footsteps that the man in the street has not only failed to keep his place with it, but has had many a stumble in his efforts to do so. This is not the time or place to introduce or discuss abstruse psychological problems, and I shall be content to direct your notice to some aspects of psychology, psychopathology, and psychotherapy which specially concern us to-day.

It has been customary to describe disease as being either "organic" or "functional" in origin. The use of the adjective "organic" indicates that the disease is associated with some physical alteration of tissues which we are able to detect. The use of the adjective "functional" indicates that the disease or disorder described is attributed to a disturbance in the function of an organ without a physical change of structure such as we are able to detect. It is clear that these two varieties of disease may be closely associated in many ways. For instance, a disorder of function in an organ may be the result of a physical or organic disease. On the other hand, there may be organic disease without obvious disorder of function. Again, an organic affection of one organ may lead to a functional disturbance in another, or a disturbance of function in one part of the body may manifest itself by disorder of function in another.

Forms of Mental Disorder.

What has modern psychological medicine taught us in regard to the practical application of these truths?

1. There is a large group of mental disorders associated frequently with disturbances of health in the form of pain, insomnia, mental and physical fatigue, disorders of digestion, circulation, &c., and sometimes with grave disabilities such as paralysis, deafness, dumbness, blindness, and other apparently serious symptoms. The characteristics of this group may be briefly summarised: (*a*) Expert knowledge is required to distinguish them from diseases of organic origin with similar symptoms. (*b*) The primary cause of the disorder lies in the mind, and if the mind is relieved all other symptoms and disabilities disappear. (*c*) They are amenable to treatment by suggestion, some kind of faith, in God or man, being a necessary prelude to success. (*d*) They provide the large bulk of miraculous cures.

2. Another group comprises mental disorders which are commonly called the insanities and, although not necessarily permanent, are practically uninfluenced by suggestion, faith, spiritual healing, or any form of psychotherapy.

3. A third group includes all cases in which disorders of mind, as manifested by changes in character, personality, and conduct, are associated with, and the result of, structural changes in the brain itself. Unless the structure of the brain can be restored to health, the mental disorders cannot be relieved. Here again suggestion, faith, or any form of psychotherapy is useless.

4. In the last group we find a somewhat heterogeneous collection of mental disorders, of varying degrees of severity, of which the prime cause is to be found, not in the brain itself, but in some distant organ. Once more, the mind can only regain its health if the source of its ill-health can be detected and dealt with.

It is hardly necessary to point out that the task of allocating a particular patient to his appropriate group—and this is the first essential of successful treatment—is one which may well baffle the experienced physician, even when he is able to call upon colleagues who are experts in chemistry, bacteriology, or radiology, for their skilled assistance.

Before going further let me bring forward two facts well recognised by those who have to do with mental disorders, the significance of which cannot be overlooked when we consider the relationship of mind and matter.

An epidemic disease which has been prevalent during the last ten years and which has claimed thousands of the population as its victims, is essentially an inflammation of the brain resulting from the invasion of that organ by some form of microbe. As the result of this disease many patients have been paralysed or otherwise disabled. On the other hand, there are many who have escaped physical disabilities, but have been left entirely altered in personality. Some have lost all moral sense and yet retained a considerable degree of intelligence. In other words, a change in the structure of the brain matter has been definitely associated with an alteration in character. In such cases all attempts to restore a moral sense by means of education, training, or suggestion have generally proved useless.

Secondly, there is a common form of temporary mental disorder, of which one of the features may be a complete loss of religious faith. This disorder overtakes the faithful as well as the faithless, and it is remarkable that no amount of suggestion, persuasion, or spiritual healing avails to restore faith in God, or comfort in prayer, until health returns.

ATTITUDE OF THE CHURCH TOWARDS SPIRITUAL HEALING.

Enough has been said to indicate some of the obstacles which beset the path of anyone who ventures into the field of psychological medicine unequipped with such scientific knowledge as can only be acquired by years of specialised study and experience.

Let me now examine the present attitude of the Church towards spiritual healing. The claim to a gift of healing on the part of the clergy was based to a large extent, I understand, on the following passages from the Epistle of St. James :—

> "Is any sick among you? Let him call for the Elders of the Church; and let them pray over him, anointing him with oil in the name of the Lord: and the prayer of faith shall save the sick, and the Lord shall raise him up; and if he have committed sins they shall be forgiven him."

Taken literally, these words can be held to support the claim to a gift of healing, especially if the proviso is added that the patient must be duly imbued with faith. But is it possible to take the claim seriously when we see the amount of sickness and suffering which surrounds us on all sides? Surely, human nature being what it is, there would be no lack of faith if experience had shown that an elder of the Church, in alliance with faith and prayer, would suffice to nip all pain and suffering in the bud. We have only to recall to our minds the innumerable healers who have appeared from time to time in various countries, who have only had to proclaim the possession of a gift of healing, divine or otherwise, who have apparently cured all sorts of diseases, and who have inspired supreme faith in thousands of their clients. Faith, even if it is defined as the ability to believe that which there is no reason to think is true, is one of the commonest attributes of the human mind and, together with the almost universal fear of pain and sickness, forms an ideal and abundant soil for the work of the spiritual healer.

But I conclude that the weight of authority in the Church is now against the claim to heal "organic" disease. Thus the Committee of the Ministry of Healing appointed by the Archbishop of Canterbury in 1920, say :—

> "Our Committee has so far found no evidence of any case of healing which cannot be paralleled by similar cures wrought by psychotherapy without religion, and by instances of spontaneous healing which often occur in the gravest cases in ordinary medical practice."

A committee more recently appointed by the Grand Assembly of the United Free Church of Scotland appears to take much the same views as one may judge from the following extract from its report :—

> "It is claimed by many that God, in his grace not only does (both in organic and functional diseases) what neither medicine nor suggestion can do, but also that by faith and prayer His people may link themselves with Him in working the miraculous . . . . Mr. Maillard . . . . is no believer in coöperation between spiritual healers and medical practitioners. Sickness is in all cases, he holds, due to spiritual causes, and thus amenable to spiritual treatment. Accordingly, he argues that a child brought up on a foundation of spiritual truth and watched by guardians walking by faith, till he is able to walk by himself, will be saved from the harvest of children's complaints like measles, whooping-cough, so commonly deemed inevitable. And if the question be asked by what methods this power and love are brought to bear on sufferers, his answer is by the Holy Communion. Teaching of this nature," say the Committee, "is to be deplored. But the pity is that there is so much of it."

The claim to heal *organic* disease by spiritual means does not receive much support, therefore, from either committee, but later in the Scottish report appears the sentence: "The chief sphere of the physician's work is the body, of the minister the soul."

No reference is there made to the mind, if it be assumed, as it generally is, that the mind and the soul are not synonymous terms. But I hope that I have made out a case for the mind sufficiently strong to prevent its falling between two stools. There can be little doubt that more than half the ills to which man is prone originate in disturbances of the mind. There can be no doubt that they are more difficult to recognise, to classify, and to treat than those of purely bodily origin, and that the dangers attached to unskilled practice in that department of medicine are at least equal to those associated with ignorant interference in any other. A smattering of modern psychology unbacked by any knowledge of general medicine constitutes no valid certificate of fitness to solve the problems presented by the vagaries and disorders of the human brain.

The last sentence of the Committee of the United Free Church should not be left unquoted :—

> "But on no conditions can the Ministry forget that they have a charge to keep with the soul of the sick, and that in the hour of need, the Physician of the soul is as timely a friend as the Physician of the body."

With that sentiment I am in entire sympathy.

FAITH.

There remains but one other aspect of my subject to which I feel compelled to refer although with a sense of diffidence which it is not so easy to be rid of as to express. It concerns "faith," a word in constant use throughout religious history. The meaning and origin of faith have been the subject of theological controversies for centuries and will, I think, arouse the interest of psychologists for many years to come. "Faith," says the writer of the Epistle to the Hebrews, "is the substance of things hoped for, the evidence of things not seen."

This definition, the best I have met with, is not lacking in beauty and simplicity of language or conception, and it has the advantage of offering to us a meaning applicable alike to faith in God and faith in man. It is comprehensible to most people because there can be few of us who have not at some time or another experienced the feeling which these words so aptly describe in relation to some other human being. There must be a large number of us who entertain or have entertained the same kind of sentiment towards our particular conception of the Almighty Deity, whether it be that of the man of science or that of the church-goer.

At the same time experience must convince all seekers after truth that the capacity for faith varies in different individuals and, indeed, may be entirely wanting in some. A little thought, too, must satisfy us that faith in God, at any rate, is not a congenital but an acquired attribute of the human mind, and which, like most other attributes, is favoured or

voured by such factors as heredity, education, and vironment. The view of certain theologians that is the "persuasion of Christian truth wrought in the art by the Holy Spirit" is not one which will adily satisfy the scientist with a leaning towards ychology. The latter may be tempted to compare th with a sense of music, a sense of colour, or a se of humour, other mental attributes with the ne variations in hereditary potentiality and in velopmental capacity.

But however divergent may be the opinion of the entist and the theologian on this subject, the mer cannot fail to recognise the reality of faith l the immense power for good and happiness ich it exercises in the lives of a large proportion the community.

I seem to have wandered away from my subject l to have risked an excursion on to very dangerous und without justification, but this is not altogether case. What I have said in regard to faith does ncern what has gone before. It is incumbent on that I should answer one inevitable question: spiritual healing can produce cures comparable those of medicine and comparable to those of cks in cases of "functional" disorder, why uld the clergy not undertake that task? My ly to them would be: You will find a propor- n of cases without faith, or without sufficient h, in God, who will not respond to your ministra- ns. And, further, you will have some cures to r credit which are not the result of spiritual ling but due to a faith which *you* have aroused, in God, but in your own person; and you will always find it easy to allot the credit to its proper rce.

CONCLUSION.

am conscious that time, not desire, prevented me, le outlining the parallel history of medicine and Church, from doing justice to the magnificent k the latter has done in the past not only in rd to its own vocation, but in the promotion of and literature. I am aware, too, that I omitted record many instances of generous patronage owed by the Mediæval Church on individual ntists.

s far as I can see, there can be no cause for gonism between medicine and the Church, and have made the one bone of contention which between them the subject of my address I e done so in the hope of fanning the fire which, ner or later, will certainly reduce that bone to s.

et me assert, without fear of contradiction, that e can be no rivalry between the two professions that medicine has no fear of the Church as a rival petitor. Any fears I may entertain are for the rch who, if she listened to some of her disciples, ht find herself in competition, not with medicine, with quacks and charlatans.

have taken the courage of my profession in my hands to-day and have declared that we make claim to cure disease. I look forward to the when the Church will have the courage to say she makes no claim to spiritual healing. She never lack the means or the scope for ministering he sick and sorrowful, and from time to time she wipe the eye of medicine.

ut for the sake of those who suffer from disease, ther of body or mind, let the Church's share in riation be summed up in the seven words: was sick, and ye visited me."

ir Farquhar Buzzard's address was illustrated by s presenting the portraits of six leaders of medicine se work exemplified in particular great stages in ntific progress. These were Servetus, Vesalius, vey, John Hunter, Charles Bell, and Hughlings kson. Of the last he said:]

nd now I must remind you of York's greatest ribution to the science of medicine, of a man m posterity will honour as the father of neurology. fer to John Hughlings Jackson, who was born at Green Hammerton, only a few miles from here, on April 4th, 1835, and who studied medicine first in this city and later at St. Bartholomew's Hospital, returning here as house surgeon to the dispensary. After three years he migrated again to London, where for the rest of his life he was intimately associated with the London Hospital in Whitechapel and the National Hospital in Queen-square.

My claim to remind you of Hughlings Jackson is based on sound foundations, on memories more intimate perhaps than those of anyone else now living. His short and barren married life ended with the death of his wife in 1876. Thereafter for five and twenty years he was a constant, almost daily visitor to my father's house, and among my earliest recollections are those of this quiet, restless spirit appearing unannounced at any time of day and disappearing without ceremony ten minutes later. His life was a lonely one, and these visits, with less frequent ones of a similar character to one or two other houses, constituted almost his only social activities. He abhorred all public and social functions. He would generally come at lunch time, having lunched already, take a chair, contribute a few pertinent and drily humorous remarks to the conversation, mutter something about a mythical engagement, and vanish. Occasionally he would invite one or other of us to drive with him, but we had to be ready in two minutes if we accepted the suggestion. If we had ever treated him as a formal guest, made any effort to prolong his stay, or even got up and seen him out of the house, we should have risked frightening him away altogether.

Later I became his clinical clerk, house physician, and, finally, colleague at Queen-square. What a difficult man to describe even with all these opportunities of knowing him! Gifted with almost feminine tact and sympathetic tenderness he was never known to say an unkind word of anyone. Diffident about his own achievements, he was scrupulous to an almost quixotic degree in giving honour where honour was due. It was impossible for anyone who knew him to associate him with any thought or action lacking in bigness, truth, or generosity. And with all this no trace of priggishness or false piety. On the contrary, perfect manliness of demeanour combined with an abundant sense of dry humour.

On the intellectual side I have no hesitation in describing him as the finest and most stimulating brain with which I have ever come in contact, and that is the almost universal judgment of those who shared, however humbly, in his work. His powers of accurate observation and meticulous attention to detail were only equalled by his uncanny genius for deduction and generalisation. As a result he arrived at truths in advance both of his contemporaries and of his followers, and established himself for all time as the father of modern neurology and perhaps as the favourite uncle of psychology and physiology.

The name of Hughlings Jackson is remembered and revered all over the scientific world. Should it not also be revered and remembered in York, his native city, the city he loved and visited almost every year of his long life? His fame is of the kind which not only endures but grows as time passes on, and in less than eight years we shall, in London, be celebrating the centenary of his birth. In Queen-square we have a statue worthy of him. Is it too much to hope that, by 1935, York, too, may possess some fitting tribute to the memory of one of her greatest sons?

STOCK EXCHANGE HELP TO HOSPITALS.—The governing body of St. Mary's Hospital, Plaistow, E., has refused to accept money from the "Help Yourself Society" scheme of the Stock Exchange Dramatic and Operatic Society on the ground that to do so would be to encourage gambling. Last year the society distributed more than £42,000 among over 100 hospitals, and it is expected that a much larger sum will be raised this year.

THE PRESENT POSITION OF

LARYNGECTOMY FOR CANCER OF THE LARYNX.*

BY LIONEL COLLEDGE, M.B. CAMB., F.R.C.S. ENG.,

SURGEON TO THE EAR AND THROAT DEPARTMENT, ST. GEORGE'S HOSPITAL, LONDON.

LARYNGECTOMY has been widely practised and much discussed in recent years. It has been performed frequently in totally unsuitable cases and has been attended by a high mortality in the hands of many, and in the hands of a few under certain conditions it has been made a safe operation. It seems, therefore, a good time to take stock of the position which laryngectomy holds in relation to cancer in and around the larynx, being an operation at first sight so hazardous and severe as to be scarcely justifiable.

Laryngectomy has been used for extrinsic cancer of the larynx, has been combined with partial excision of the pharynx to the post-cricoid carcinoma of women, and has been applied to growths arising in the fossa pyriformis. At the present time, however, its use is almost limited to cases of intrinsic cancer too advanced for any conservative operation—that is, laryngo-fissure or partial excision. In such cases the pharynx is not invaded, and only so much of it need be removed as is necessary anatomically to excise the larynx; its closure presents no serious difficulty, and there is usually no need for any plastic operation nor the use of skin-flaps. Many lasting cures can be claimed. Such cases of advanced intrinsic cancer include the following types:—

(*a*) Where the disease has extended at all widely to the subglottic region. There is a high percentage of recurrence after laryngo-fissure in this condition, owing to the difficulty of elevating the mucous membrane below the lower edge of the thyroid cartilage, and the ease with which the disease spreads through the crico-thyroid membrane and crosses the middle line.

(*b*) Where the disease crosses the anterior commissure and invades both vocal cords.

(*c*) Where one or both vocal cords are fixed and there is extension to the arytenoid region. Although fixation of one cord does not necessarily contra-indicate laryngo-fissure, yet such cases show a large percentage of failures, and the question whether this operation or a partial or total excision of the larynx is the appropriate operation must be considered in each individual case. Hemilaryngectomy, or some modification of it, will result in a better voice and less social disability, but a permanent tracheotomy may be necessary afterwards in spite of the attempt to preserve an airway through the larynx, and there is a greater risk of recurrence.

(*d*) Where both vocal cords, the ventricular bands, and the subglottic region are attacked, and the larynx is choked with growth, no doubt can arise that laryngectomy is the proper operation.

(*e*) Where the disease has recurred after laryngo-fissure, though occasionally a second fissure or partial excision may succeed, laryngectomy should generally be preferred to a lesser operation. I have done this seven times on patients who had previously undergone laryngo-fissure. Of these four died within a year from another recurrence, one died from heart disease clinically free from any sign of cancer, and two only remain well six years and three years respectively since the laryngectomy. Recurrence after a laryngo-fissure, therefore, is not so hopeless as has been thought, but the outlook is clearly not very encouraging.

There are certain other considerations, of whi the recognition has influenced the results of operati beneficially. The decision whether laryngo-fissu laryngectomy, or some intermediate procedure is t appropriate operation for the case is of the utm importance. This decision should be made bef any operation is begun, and not left to an explorato investigation, because laryngectomy, preceded thyrotomy, is a longer and more complicated operati than a deliberately planned laryngectomy. If a doubt exists it will generally be found that lary gectomy is required, but each surgeon will be sway by his own views and experience, one inclined to sa the larynx wherever possible, another determin to place the risk of recurrence beyond every oth consideration.

Of this latter school Dr. John Edmund Macker is a prominent exponent, and records that of consecutive operations 31 were laryngectomies a only two laryngo-fissures. Later he records thyrotomies, as against 102 total laryngectomies. reference to the earlier series he writes as follow "Here I might digress and say a word on so amazing statistics of cures by *thyrotomy*, and even excision under suspension. Is it possible that general profession in the regions from which th statistics emanate is more enlightened and m alert in the detection of laryngeal cancer than we in New York and its environs?" The answer this ingenuous question is: "Why, yes, certainl Each case must be decided on its merits, and it evident that Dr. Mackenty sees a large proportion cases in an advanced stage, since he has only obtai 66 per cent. of cures after laryngectomy for intri cancer, as against 80 per cent. after thyrofissure in practice of Sir StClair Thomson. Here, especia as the late Sir Felix Semon quoted in this connexi it is necessary "to make the punishment fit crime." If the appropriate operation is select recurrence after thyrotomy should be extrem uncommon, but no larynx should be sacrifi unnecessarily. On the other hand, the surg should not allow himself to be forced into operat on an unsuitable case on the plea that the disea invariably fatal.

The general condition of the patient is of the utm importance, and may be a contra-indication i case otherwise suitable for operation. In this c nexion it must be remembered that in elderly pe the growth may be present for a long time be ultimately destroying life. In a case observed myself, the patient, who declined any form of op tion whatever, survived four years from the t that the growth was first recognised.

The most remarkable case is Gleitmann's, ultima recorded by Harmon Smith. A man of 33 c under observation with cancer of the larynx, pro histologically. The larynx was successfully remo 13 years later by Dr. Brewer.

Age in itself is no contra-indication. A medical m aged 73, passed through the convalescence wit any complication or even rise of temperature, returned to carry on his practice until his de some months later, from an unexpected recurr of the disease at the root of the neck. Gener however, it is natural that the younger the pat the better are the effects of the operation suppor Three patients between 40 and 50 caused very l anxiety. Those of spare build, with long, thin ne are better subjects than fat people with thick, s necks, and those addicted to alcohol are invari in a poorer position to withstand any severe operat but particularly a laryngectomy.

Prolonged dyspnœa appears to exercise a pernic effect on the general nutrition, and to cause wast Such patients withstand the effects of the opera very badly. A thin, wasted man of 56, had increasing dyspnœa, which would soon rendered a tracheotomy essential to life, succum to sloughing and septicæmia in a week, altho he was edentulous and in other respects a suit subject.

* Excerpt from the Semon Lecture delivered under the auspices of the University of London in the Barnes Hall of the Royal Society of Medicine on Nov. 3rd.

RATE OF MOVEMENT IN POST-ENCEPHALITIC PARKINSONISM.

By ARTHUR J. HALL, M.D. Camb., F.R.C.P. Lond.,

ROFESSOR OF MEDICINE, SHEFFIELD UNIVERSITY; PHYSICIAN, SHEFFIELD ROYAL HOSPITAL.

(*From the Department of Medicine, Sheffield University.*)

THIS paper records an attempt to obtain some formation as to the slowness of movement in arkinsonians by means of direct measurements of e rate at which a definite group of movements n be repeated during a definite period of time. For this purpose I selected side-to-side movements the arm over a distance of 18 in., with an obstacle in. high midway between the two points. This st is simple and easy to carry out and to measure, d can be done whilst sitting, so that even advanced ses can be examined. The apparatus (Fig. 1) nsists of an oblong board (3 × 1 ft.), in the centre which is a vertical board 4¾ in. high, fixed at right gles to the long axis of the base. On each side this is a make-and-break key, consisting of two t, rectangular ces of ebonite the upper × 4 in., the ver 8 × 6 in. e two keys 18 in. apart, m centre to ntre. They hinged at end away m the patient, ilst they are parated in centre by light spring, that the ls nearest the tient are ut an inch art. The htest down-d pressure the upper e breaks ircuit connected with terminals on the key. s remains broken until all pressure is removed n the upper piece. The terminals are con-ted with a Mackenzie polygraph recording aratus and an electric signal. The board is ped firmly along the edge of a table of con-ient height, and the patient sits facing the aratus on an adjustable stool. The end of the ight board should be exactly opposite the middle his sternum. The right arm is always tested . The action measured is not a single move-t from one key to another, but a *double to-and-fro ement from one side to the other and back again.*

he rate in most Parkinsonians can be easily nted without the recording apparatus by listening he alternate sounds of the keys, and timing by watch. Before beginning the test, the patient ully informed as to what is wanted of him—ely, that he should keep moving the hand from to key *as quickly as he can for a whole minute.* ept that he is told when to start and when to , nothing is said during the investigation. This mportant, as any kind of suggestive stimulus cause considerable change in the rate.

tandard figures for this apparatus were obtained n 23 males and 48 females—all healthy persons veen the ages of 19 and 40. The results were :—

Average Number of Double Strokes in One Minute.

	Right arm.	Left arm.
Males	125	115
Females	108	100

in each sex a difference of 8 per cent. between the two arms).

These numbers were taken as the normal for the corresponding arm, and the rate in each limb is expressed as a percentage of this. In left-handed persons these standards were found to be reversed.

In order to compare the degree of slowness in different cases, four groups have been made according to the number of double strokes per minute, expressed as a percentage of the normal standard for the corresponding arm and sex :—

Group A.—Rates between 75 per cent. and normal—i.e., at least a three-quarter rate.
Group B.—Rates between 50 per cent. and 75 per cent. of normal.
Group C.—Rates between 25 per cent. and 50 per cent.
Group D.—Rates below 25 per cent.

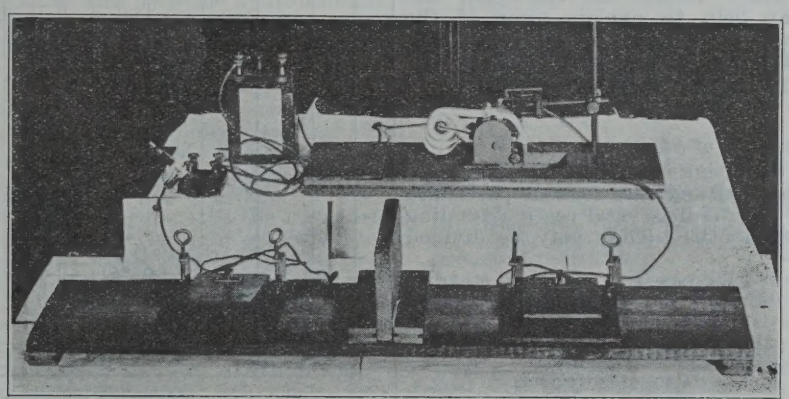
General Results.

Seventy-three Parkinsonians have been tested in this way. When grouped according to their quicker arm, they are distributed as follows :—

	48 males.		25 females.	
Group A	19 %	52 %	8 %	52 %
„ B	33 %		44 %	
„ C	42 %	48 %	24 %	48 %
„ D	6 %		24 %	

Only one showed a rate of movement which reached the normal average (in one arm only). Not more than half a dozen reached a rate equal to the minimum normal with either arm.

FIG. 1.



The measuring apparatus complete with recording instrument attached.

As these tests were not begun until November, 1925, and most of the cases tested had their acute attack of encephalitis in the spring of 1924, most of them cannot be looked upon as early cases. In some, however, Parkinsonism had only shown itself for a short time and there was no subjective complaint of slowness, yet when tested they were found to be definitely below the normal standard of rate of movement in both arms. Moreover, when slight stiffness and slowness was complained of in one arm only, the other arm was (with one exception) found to be slow as well.

There exists, therefore, a general slowness of movement, and one more widely spread than the particular slowness in one limb which the patient notices himself, and for which he seeks advice. One very active business man, who had improved remarkably after taking belladonna, was quite indignant when asked if he was any slower in his movements than before, and yet he only reached a rate of 80 per cent. with the right arm and 87 per cent. with the left.

This general slowness is also shown by comparing the average difference between the two arms in Parkinsonians with that of our normal standards. In 23 normal men and 48 normal women the average proportion of right arm to left is as 100 to 92 in each sex. In 48 Parkinsonian men it is 100 to 84; in 25 Parkinsonian women 100 to 86. There is never any extreme difference. In no case does one arm come into Group A, the other into Group D. Although in the earliest stages one arm may show definite slowness whilst the other remains normal, yet, so far as these records go, this is not usual at the stage at which patients come under observation, and it would seem that a generalised slowness of movement appears very early.

Flagging.

There is a general impression that a Parkinsonian tires quickly, and that he is unable to keep up any voluntary muscular effort for more than a short time. In order to test this, a number of normals and of Parkinsonians have been examined, and their respective rates of movements estimated in each successive quarter of a one-minute test "as quick as you can." Figs. 2 and 3 (solid lines) show the normal averages for each arm obtained from healthy young adults (16 males and 41 females), chiefly students and hospital nurses. In these charts the average number of strokes made in the first quarter-minute of each corresponding series of tests, whatever it may be, is always called 100, and the average in each succeeding quarter-minute expressed as a percentage of that. The amount of flagging varies, but in no case exceeds 10 per cent. in the normals.

Parkinsonians, in Groups A, B, and C, show practically no more tendency to "flagging" than do normal persons (Figs. 2 and 3). Their rate is slower, but they keep it up well for a whole minute. Marked flagging does not appear until a serious amount of slowness is present (less than quarter rate). Thus, in Group D, in both sexes and in both arms, it is present in an extreme form, whilst in females (left) it is present to a lesser extent even at rather higher rates (Fig. 3). These results are somewhat unexpected, and may help to explain some of the anomalies which have been noted by others.

Measurements of the polygraph records show that only a very small proportion of this flagging is due to increased delay in starting; it is chiefly in the act of movement.

Progress of Slowness.

By this method of testing it is possible to measure the progress of a case, at any rate for this particular feature. We have records in several cases extending over more than 18 months. They may be divided into two groups:—

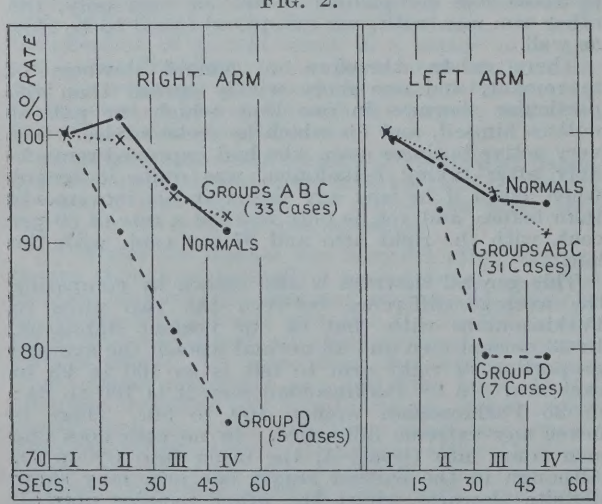
(*a*) Those that have increased in slowness steadily and progressively, of which the following case is an illustration:—

Female, aged 17. Primary attack May, 1924.

	Rate of movement— Right arm.	Left arm.
Nov. 2nd, 1925 ..	48 per cent.	45 per cent.
March 17th, 1926 ..	20 ,, ...	38 ,,
May 12th, 1926 ..	16 ,, ...	29 ,,
Oct. 13th, 1926 ..	17 ,, ...	28 ,,
March 2nd, 1927 ..	12 ,, ...	17 ,,

In this case belladonna had no beneficial effect.

FIG. 2.



Flagging (males). In Figs. 2 and 3 the columns I., II., III., IV. represent the four consecutive quarters of one minute. The number of strokes in the first quarter minute, whatever its actual amount in each group, is called 100, and the rates in succeeding quarters is calculated to this percentage.

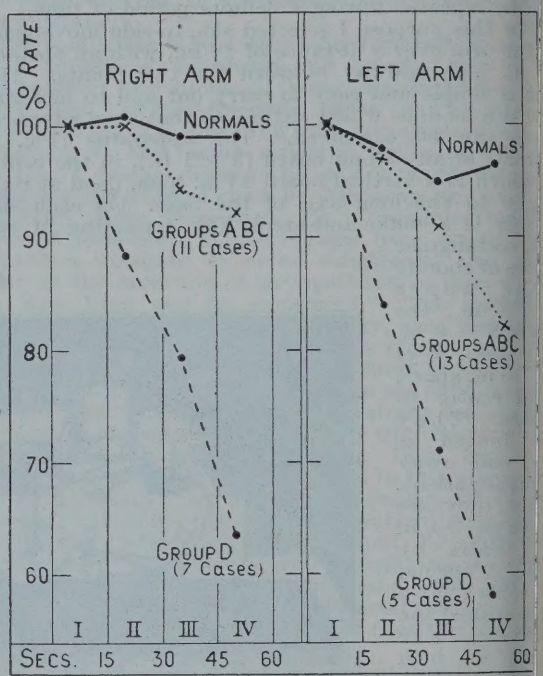
(*b*) Those that have remained at about the same level since first examined, as in the following case:—

Male, aged 24. Primary attack March, 1924.

	Rate of movement— Right arm.	Left arm.
Nov. 13th, 1925 ..	50 per cent.	34 per cent.
April 28th, 1926 ..	48 ,, ...	42 ,,
July 14th, 1926 ..	46 ,, ...	33 ,,
Oct. 20th, 1926 ..	39 ,, ...	34 ,,
Feb. 23rd, 1927 ..	47 ,, ...	42 ,,

Some of this group will be referred to later discussing the effect of drugs. In one case, ev

FIG. 3.



Flagging (females).

after nine years' duration of Parkinsonism, the r is still 57 per cent. right, 63 per cent. left.

The Effect of Belladonna on the Rate of Movement Parkinsonians.

Improvement, which may for a time be surprisi sometimes follows the administration of belladon In many cases, however, the effect is but slight, a in others it is nil.

Fig. 4 shows the most striking effects in my ca It will be seen from the chart: (*a*) that belladon can produce a definite increase in the rate of mo ment; (*b*) that such increase is at most about 25 cent. of the normal rate, usually considerably l (*c*) that it is usually very similar on the two sid whatever may have been the previous rates a however widely they may have differed in the t arms. In all the cases recorded there was only exception. In this man the right arm increa only by 4 per cent., whilst the left increased 29 per cent. There is some uncertainty about figures in this case, and if correct, it is quite exceptio The time during which the drug has been ta varied from one week to 16. Any effect usually occ within a week, and our records unfortunately sh that the improvement does not increase as the we go on, although the rate may remain at the hig level for many months under the influence of the dr

Effects of (a) Physical Exercises, and (b) Hyoscine Hy bromide on Rate of Movement in Parkinsonians.

Four men in whom Parkinsonism followed attack of encephalitis in the spring of 1924, and w for various reasons, had become inmates of the So

Yorkshire Mental Hospital, were tested for rate of movement on Nov. 15th, 1926, before any definite treatment was adopted (Fig. 5, columns I.). A week later, on Nov. 22nd, daily physical exercise, together with marching, was commenced. After about three months they were tested again, and all showed a diminution of rate in each arm, varying from 14 per cent. to less than 1 per cent. (Fig. 5, columns II.). This was thought to be the natural progress of events. The physical exercises were continued and two months later daily hypodermic injections of hyoscine hydrobromide, gr. 1/100, were given in addition. On August 21st, 1927, about 14 weeks after the hyoscine treatment was begun, they were again tested. All showed definite improvement (Fig. 4, columns III.). Thus, like belladonna (*a*) hyoscine hydrobromide can produce a definite increase of rate of movement. (*b*) the total increase is at most about 25 per cent. of the normal rate, usually considerably less; (*c*) it is usually about equal on the two sides.

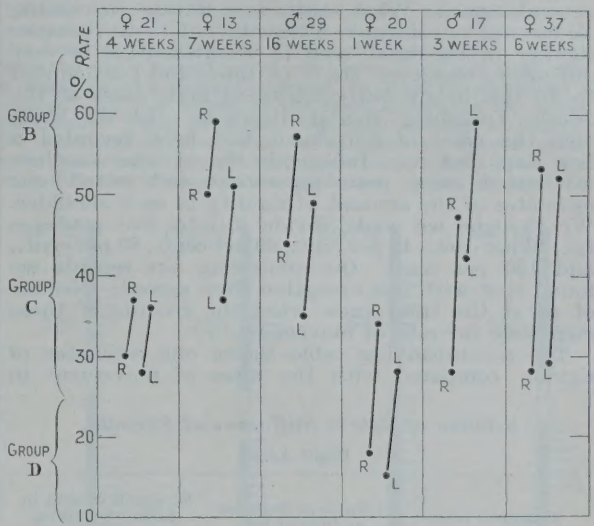
Effect of a Mental Stimulus.

"Kinesia paradoxa" is a well-known phenomenon in these cases, particularly in the movements of running. If it is present in the arms it should be measurable.

An opportunity of testing this offered itself on August 21st, 1927, in these four men who had been treated for three months with hyoscine hydrobromide. The following method was adopted. When the man was brought into the room he was asked to try the test again and do his very best so that we could see how much better he was. The conditions as regards silence and so forth were exactly as on previous occasions. When he had completed his test for both arms (vide Fig. 4, columns III.) and had a short rest, a packet of cigarettes was produced and put on the table in front of him. He was then told that if he could beat his previous rate with the right arm he would win the cigarettes. The right arm was then tested. When this was done, another packet was similarly produced as a prize for the left arm, and the left arm tested. The same procedure was adopted in each case, excepting that when the supply of cigarettes ran out sixpence was substituted as the prize. The results for each case are shown in Fig. 5, columns IV. The stimulus may not seem very great, but to inmates of an institution cigarettes or sixpence mean a good deal.

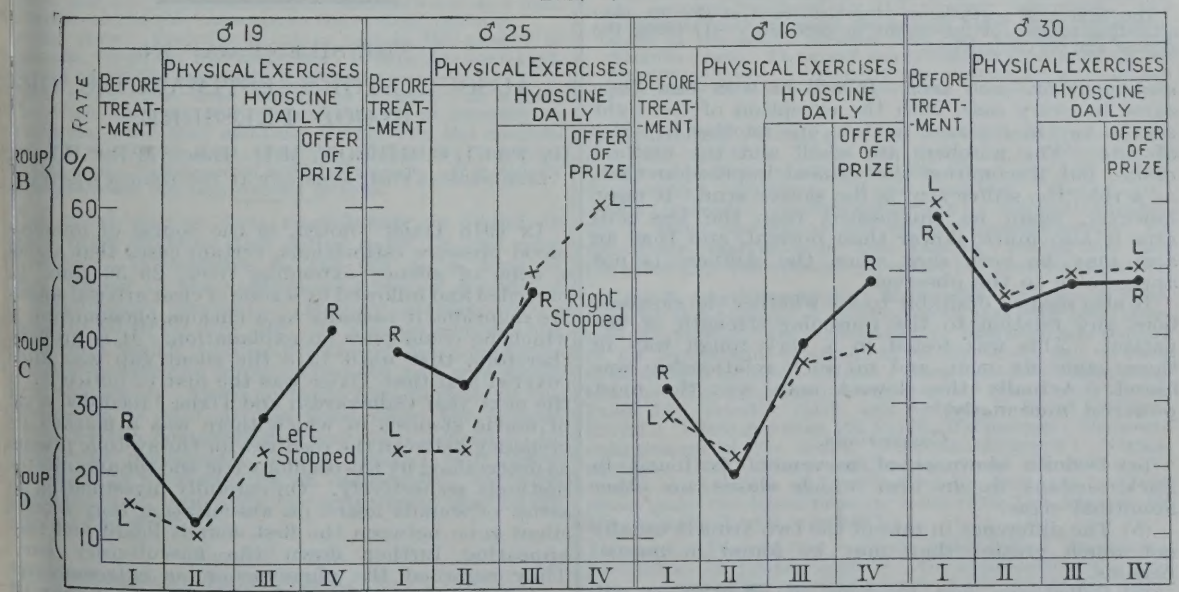
It is clear that with a mental stimulus the rate shown under ordinary conditions is capable at most of rather more than a 10 per cent. increase, and I am satisfied that none of these men could have done more than they did, however great the stimulus. It is, therefore, probably an exaggeration when Parkinsonians with pronounced slowness are said suddenly to make movements "as well as ever they did in their lives." The relative increase of rate appears greater than it really is, but is probably always much below normal. Whilst, however, there may be a reserve which can be released by an adequate stimulus, these records show that a limb which, under ordinary conditions, is not much slower than its fellow, has not a similar amount of "reserve," and that any attempt to call it forth fails in one way or another—either it exhausts itself very rapidly with

FIG. 4.



Effect of belladonna on rate of movement. R = right arm; L = left arm. In each the lower point is the rate before, the higher after taking belladonna. The number of weeks between the two estimations is given at the top of the column for each of the six cases.

FIG. 5.



Shows a series of four observations in each of four cases. Those shown in the columns marked I. were made on Nov. 15th, 1926, before treatment began; those in columns II. were made on March 3rd, 1927; whilst those in columns III. were made on August 21st, 1927. Physical exercises were started on Nov. 22nd, 1926, and continued daily until August 21st. Subcutaneous injections of hyoscine hydrobromide were given daily from May 5th to August 21st.

complete and abrupt stoppage, or the increase is only extremely slight. This complete abrupt stoppage of one arm only in two of the cases is a curious phenomenon. Both were obviously distressed at having to stop. One of them told me that his shoulder became "fixed" and he could not move it. The other could not give any reason. It appears as though in these cases of abrupt and complete "stoppage" some factor not present in the other arm comes into play.

So far, little or nothing has been said about "rigidity" of the arms (using the term in the most general sense). What share does it take in causing slowness of movement? This is difficult to say, because rigidity of the kind seen in Parkinsonians is very difficult to measure. Dr. C. G. Imrie and I attempted to do this in six fairly advanced male cases at the South Yorkshire Mental Hospital. In all these men the rates of movement had been recorded a few days before. Independently of one another, we tested each man separately and noted our estimates of the amount of rigidity in each shoulder. We thought we could divide it into five grades—i.e., 20 per cent., 40 per cent., 60 per cent., 80 per cent., and 100 per cent. On comparing our records we found that with one exception they agreed. Neither of us at the time knew what the records of these men were for rate of movement.

The accompanying table shows our estimates of rigidity compared with the rates of movement in

Relation of Rate to Stiffness and Strength.

The figures in parentheses give the order of the six men according to rate of movement in each limb—(1) being the slowest and (6) the quickest.

each man for each arm. It will be seen that they agree in every case, with the exception of the right arm in two men placed next to one another in order of rate. The numbers are small and the method crude, but it confirms the clinical impression that, as a rule, the stiffer arm is the slower arm. It may, however, again be emphasised that the less stiff arm is also much slower than normal, and that an arm may be very slow when the stiffness is not appreciable to the observer.

It also seemed desirable to see whether the slowness bore any relation to the muscular strength of the patient. This was tested in a very rough way in these same six men, and no such relationship was found. Actually the slowest man was the most powerful muscularly.

Conclusions.

(*a*) Definite slowness of movement is found in Parkinsonians in an arm which shows no other abnormal signs.

(*b*) The difference in rate of the two arms is usually not much greater than may be found in normal persons.

(*c*) Belladonna and hyoscine, if effective at all, usually act to almost the same extent on both arms.

(*d*) In all but the advanced degrees of slowness there is little or no abnormal flagging.

All these facts taken together support the view that the primary seat of diminished rate of movement does not lie in the peripheral motor apparatus, and that it is, therefore, probably in the central nervous system. This is the primary factor in causing slowness of movement, to which others may be added secondarily. Thus, the primary diminution of rate may be increased by a functional element the extent of which can be unmasked by a suitable mental stimulus. It varies considerably in different cases and at different stages.

In most cases it is not marked in the lighter or medium stages, but as the disease progresses may become an important factor in increasing the slowness. Changes in the peripheral motor apparatus may further magnify the disability. Of these, muscular "stiffness" seems clinically the most important and attempts at its measurement support such a view. Possibly this factor plays a part in causing the extreme flagging found in very slow cases. Actual muscular weakness does not seem to enter into the slowness recorded in these measurements to any extent comparable with that of stiffness.

The phenomenon of "sudden stoppage," seen in two cases of advanced Parkinsonism in one arm only, requires further investigation.

These conclusions support the views expressed by Kinnier Wilson [1] in his Croonian Lectures of 1925 that akinesia is the result of more than one factor and that the condition of the peripheral motor system is no more than one of the causes and not necessarily the most important. Cruchet,[2] from clinical observations and from the experimental work of his pupil, Delmas-Masselet, has also come to the conclusion that bradykinesia is independent of hypertonus.

My thanks are due to Dr. Elsa Paige, my assistant in the clinic for encephalitis cases at the Sheffield Royal Hospital, for much laborious work in taking records; to Drs. W. J. N. Vincent and F. T. Thorne at the South Yorkshire Mental Hospital for their aid in the investigation of cases there; and to Dr. C. G. Imrie for constant help.

The expenses connected with this investigation have been defrayed by the Medical Research Council, for which I also desire to express my thanks.

THE SILENT GAP IN AUSCULTATORY ESTIMATIONS OF BLOOD PRESSURE.

BY PAUL C. GIBSON, M.D., B.Sc., M.R.C.P.LOND.,
LATE MEDICAL FIRST ASSISTANT AT THE LONDON HOSPITAL.

IN 1918 Tixier [1] noted, in the course of numerous blood pressure estimations, certain cases that showed a zone of silence extending over 20–30 mm. H., preceded and followed by a zone of clear arterial sound. He mentions it casually as a curious phenomenon for which he could offer no explanation. It is probable, therefore, that until 1918 the silent gap was uncovered and that Tixier was the first to notice it. In the next year Gallavardin and Tixier [2] recorded a case of aortic stenosis in which there was a marked discrepancy between the readings for the systolic pressure as determined by the oscillometric and the auscultatory methods respectively. On carefully investigating the series of sounds heard on auscultation they found a silent zone between the first sounds heard and those appearing further down the auscultatory curve. They regarded the phenomenon as extremely rare and stated that this was the first time that they had encountered it in many thousands of estimations. Shortly after this Poulain [3] recorded his experience of the same abnormality and came to the conclusion

at it was a sign of aortic stenosis. In the same year tienne and Richard [4] noted its occurrence in the sence of aortic stenosis, and in 1921 Gallavardin d Barbier,[5] as the result of further investigation, ated that the "trou auscultatoire," as they called was not pathognomonic of aortic stenosis and that, fact, it was more commonly met with in other nditions; they found that in people over 60 with rtension the phenomenon was not rare. About e same time Barbier [6] stated that among the old en of the Hospice du Perron he had found it in one t of every two patients. He with others regarded e "trou" as the acoustic equivalent of the anacrotic lse. For the last six years, therefore, the silent gap, lled in France the "trou auscultatoire," has had full cognition by French physicians, and it is remarkable at it should have escaped notice in this country.

The Auscultatory Sequence.

Before describing the silent gap it will be useful to e an account of the routine method adopted for imating the blood pressure, and to mention the in features of the so-called "auscultatory curve."

After applying the armlet of a Riva-Rocci sphygmomanoter, the pressure in it is rapidly raised to about 250 mm. and then allowed to fall slowly and steadily while the erver listens with his stethoscope over that part of the chial artery which lies nearest the lower margin of armlet. The pressure registered by the manometer when first sound is heard is taken as the systolic pressure, the point at which the loud sounds suddenly become s is taken as the diastolic pressure. After this point is sed and the pressure has fallen another 5 mm. or so the nds usually cease. The proceeding should be repeated e or twice until consistent readings are obtained. It is portant to control the readings for the systolic pressure by pation of the radial artery. Usually the first sound appears he ear at a level which is a few millimetres higher than that which the pulsations of the radial artery become palpable.

The series of sounds heard, from their first appearce at the systolic pressure to their final disappearance t below the diastolic reading, constitute what rotkow described as the auscultatory curve, but prefer to call it the auscultatory sequence. The uence of sounds can be more or less clearly divided o four zones, following one another in a continuous es, of which the order is constant but the extents he second and fourth zones vary considerably not y from one individual to another but also in the he individual under different conditions.

irst zone: Constant in type and in extent, of short ation and easily missed, as the sounds are soft and dull. first sound in this zone marks the systolic pressure.

econd zone: Variable in extent and in the quality of sounds, which are like murmurs. It is in this zone that, ertain cases, the silent gap is found.

hird zone: The most distinctive of all. The sounds loud and slapping and increase steadily in intensity to aximum, when they suddenly change into the minimal nds of the fourth zone, the point of diastolic pressure.

ourth zone: Composed of soft, dull sounds. It is usually hort duration but may extend to zero.

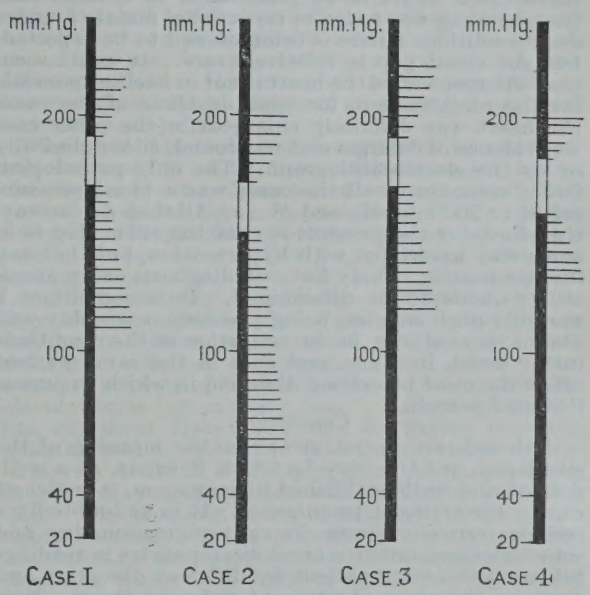
The silent gap or *trou auscultatoire* is found in ain cases dividing this series more or less near centre. It appears to the ear as a zone of nce instead of the continuous series of sounds of auscultatory sequence. It may extend over a nge of 20 to 60 mm. Hg. It always occupies the nd zone, which it more or less replaces, sometimes earing nearer the upper extremity and sometimes rer the lower. An important characteristic of the nomenon is that at the time when the sounds tted by the compressed artery have ceased to be ible, the movements of the arterial wall below armlet, as measured by an oscillometer, show no tement, and, moreover, the pulse wave may easily elt at the wrist.

Typical Cases.

few examples may be quoted.

ASE 1.—*Arterio-sclerosis; neurasthenia.*—A male, aged 62. history of previous illness until six months ago; since he has suffered from general debility and occasional cks of palpitations and giddiness. Passing large quantities of urine. On examination no evidence of disease was found apart from the cardiovascular system. His urine contained no albumin. Heart: Apex-beat external to nipple line. Impulse forcible. No murmurs. Pulse 66. Regular except for occasional intermissions. Radial arteries thickened and tortuous. Blood pressure 225/110. Silent gap between 190 and 170. Wassermann reaction: Negative. Electrocardiograph: Normal rhythm. Left ventricular preponderance, T1 flat. He was kept under observation for nine months. During this time there were no signs of circulatory failure. The silent gap persisted throughout, varying slightly in extent. His condition improved considerably with rest and tonic treatment.

CASE 2.—*Syphilitic aortitis; aortic incompetence.*—A male, aged 69. Four years previously was an in-patient at the London Hospital with functional dyspepsia. At that time the aortic second sound was accentuated and there was a suggestion of a diastolic murmur. He came to out-patient's complaining of a return of the same symptoms six weeks previously. Pain, flatulence, vomiting, and loss of weight. On examination there was no evidence of disease apart from the cardiovascular system. Heart: Apex-beat felt with difficulty internal to the nipple line. A musical diastolic murmur heard well all over the precordia and conducted into the carotids. Pulse 56, collapsing; radials much thickened. Blood pressure 200/60. Silent gap 170 to 150. Wassermann reaction: Weak positive. Radioscopy: Aorta normal. Electrocardiograph: Normal rhythm, T1, 2, and 3 upright, no left or right preponderance. He was under observation for four months. During this time the silent gap was constantly present but variable in extent.



A diagrammatic representation of the silent gap, as found in the four cases described. The vertical column represents the pressure registered by the mercury manometer. The horizontal lines represent the sounds heard with the stethoscope as the armlet pressure falls from the systolic to the diastolic levels. The silent gap is denoted by a blank in the pressure column. To simplify the diagram no attempt has been made to represent the complete auscultatory sequence.

CASE 3.—*Arterio-sclerosis; Myocardial Failure.*—A male, aged 70. Complaining of swelling of his legs with breathlessness on exertion. On examination he had moderate œdema of his legs, slight enlargement of the liver, and a trace of albumin in his urine. Heart: Apex-beat forcible, external to nipple line, no murmurs, aortic second sound accentuated. Pulse 56; arteries thick and tortuous. Blood pressure 220/115. Silent gap from 190 to 170. Radioscopy: Moderate enlargement of the heart. Electrocardiograph: Normal rhythm. (N.B.—The practitioner who sent this case up for special examination was puzzled by the fact that he could never make the blood pressure more than 170, whereas we always made it well over 200.)

CASE 4.—*Toxic goitre; simple tachycardia; paroxysmal fibrillation.*—A female, aged 54. On examination she had some œdema of her legs and a trace of albumin in her urine. Heart: Apex-beat forcible and external to the nipple line, harsh systolic murmur at mitral and aortic areas. Pulse 110 to 130, arteries not palpable. Blood pressure 200/130. Silent gap from 185 to 160. Radioscopy: Moderate enlargement of

the heart to the left. Electrocardiograph: Simple tachycardia.

The diagram illustrates these cases and gives a graphic representation of the phenomenon.

Clinical Significance.

An analysis of these cases throws little light upon the significance of the silent gap, and the following points are brought forward for what they are worth. Hardening and tortuosity of the radial arteries was noted in three of the cases, but in the remaining one the arteries were soft and could not be felt. The electrocardiogram, taken in every case, showed none of the abnormalities that we expect to find in cases of pronounced coronary disease. Only two of the cases showed clinical evidence of myocardial failure; of these, Case 3 was an old man of 70 years whose heart was labouring under a systolic pressure of 220 mm. Hg, and the other, Case 4, was a middle-aged woman with a toxic goitre, who had a persistent tachycardia and occasional paroxysms of fibrillation. In neither of these cases would it be permissible to assume that the silent gap was a sign of myocardial disease; under such conditions failure is common and to be expected, but the silent gap is relatively rare. It would seem that enlargement of the heart is not in itself responsible for the phenomenon, for while in three of the cases the heart was definitely enlarged, in the other case no evidence of enlargement was found, either clinically or by the electrocardiograph. The only pathological factor common to all the cases was a blood pressure raised to 200 mm. Hg and over. All that we can say, therefore, for the present, is that the silent gap is in some way associated with hypertension, but that any further bearing it may have on diagnosis or prognosis still remains to be determined. It is sometimes a variable phenomenon, being present on one day and absent on another; an investigation of the conditions under which it comes and goes in the same patient offers the most promising direction in which to pursue further research.

Conclusion.

Although we do not yet know the meaning of the silent gap, yet the very fact that it exists, as a well-defined and well-established phenomenon, is sufficient excuse for giving it prominence. It is undoubtedly a serious source of error in sphygmomanometry and sometimes accounts for great discrepancies in readings taken on the same patient by different observers and even by the same observer at different times. It is scarcely surprising that the clinical value of blood pressure estimations has been called in question, when it is realised that, in addition to the many recognised sources of inaccuracy, an error of 20 per cent. may creep into our readings unawares. By adopting a standardised technique for taking blood pressure, such as the one we have outlined above, one of the most serious causes of inaccuracy may be avoided, and, moreover, we should go far towards ensuring that figures obtained at different times and by different observers shall be comparable. The most valuable practical point that arises from these observations is the importance in taking the systolic pressure of always raising the armlet pressure, to begin with, to well above 200 mm. Hg.

It was at the instigation of Dr. John Parkinson that these observations were made, and I must express to him my most sincere thanks for much valuable and kindly assistance and for his permission to publish the cases, which were all under his care. I must also thank Dr. D. Evan Bedford for supplying me with literature on the subject.

ANALYSIS OF A SERIES OF CASES AFTE SUPRAPUBIC PROSTATECTOMY,

WITH SPECIAL REFERENCE TO THE REAPPEARANCE OF THE PROSTATE.

BY DAVID S. DAVIES, B.M., B.CH. OXF.,
LATE RESIDENT MEDICAL OFFICER, ST. PAUL'S HOSPITAL I GENITO-URINARY DISEASES.

Cases Investigated Jointly with

F. MC.G. LOUGHNANE, F.R.C.S. ENG.,
SURGEON TO ST. MARY'S HOSPITAL, PLAISTOW; ASSISTANT SURGE ALL SAINTS' HOSPITAL.

IN the title of this paper the word "recurrenc was avoided and the term "reappearance" st stituted. The chief reason for this was the lack agreement amongst observers as to the nature what is universally called "prostatic hypertroph" and as to the extent of removal of the gland in suprapubic operation. As will appear later, so observers hold that in hypertrophy there is no locali adenomatous overgrowth, but that the whole prost gland undergoes hyperplasia, whence it follows t suprapubic prostatectomy is a true enucleation the prostate itself, and reappearance of the gl can only be attributed to imperfect removal. Oth maintain that a hypertrophied prostate is a prost with adenomata in it, and that operation is mer a shelling-out of these new growths. Obviously t can leave the whole of the true prostate *in situ* w its power of forming new adenomata unimpair Others, again, and especially some of the Fre surgeons, affirm that a hypertrophied prostate never anything but an adenoma of the periureth glands, encroaching on the limited space occup by the prostate in its rigid capsule, and compress it so as to convert it into a false capsule whic left after operation. This can then regenerate int normal gland. "Reappearance," therefore, constitu the most suitable term.

This paper presents the results of investigati on a series of 29 consecutive cases discharged cu from hospital after suprapubic prostatectomy benign hypertrophy. The object was not only to to assess the after-results of the operation, but a and more especially, to investigate the incidence degree of reappearance of the prostate, either norma or with overgrowth. Of these 29 cases one died the meantime, and two could not be traced. number was thus reduced to 26; 16 of these had b operated on more than two years before the invest tion, 7 more than one year before, and 3 less t one year before.

The complete follow-up consisted of a sl questionaire, rectal examination, cystoscopy, posterior urethroscopy with a continuous irrigat urethroscope. Nineteen cases underwent the examination. The other seven supplied answers the questionaire, but owing to infirmity, poverty other causes were unable to attend for the phys examination. In one of the cases shown as answe the questionaire, cystoscopy was not possible, ow to a stricture of the bulbous urethra.

In the table each case is set out in two lines; first line contains the findings before operation, the second those after operation. This method tabulation allows of easy comparison of pre- post-operative states, and of a rough assessmen the benefit or otherwise of operation to the individ

The various headings may now be considered detail.

Age-incidence of Prostatic Hypertrophy.

Astley Cooper[1] said of hypertrophy of the prosta "It is the consequence of age and not of disea Brodie[2] went even further, saying that increase the size of the prostate was an invariable accomp ment of senility. "When the hair becomes g and scanty, when specks of earthy matter begi be deposited in the tunics of the arteries, and whe

hite zone is formed at the margin of the cornea, t the same period the prostate gland usually, I might erhaps say invariably, becomes increased in size." uch a statement scarcely needs Thompson's figures[3] o disprove it. He examined a series of cases of 164 ubjects at or above the age of 60 years. No selection as made, and the subjects were taken as specimens average lives at these ages. He found definite ypertrophy of the prostate in only 56, a percentage 34, though in a further 16 cases he mentions some nall tumour of the prostate. Marion[4] also examined series of 200 individuals of ages between 50 and 70, id found prostatic hypertrophy, as judged by ctal examination, in only 42 per cent. of these. nerefore, though we may deny Brodie's statement at the prostate is always enlarged in the senile, e must admit that it is so in a fair percentage of y series of cases over a certain age.

The following table (A) gives the ages of our patients the time they originally presented themselves for amination.

Table A.

Ages between			
50 and 60 years	9 cases		34 %.
60 and 70 „	10 „		39 %.
70 and 80 „	7 „		27 %.

is falls into line with Marion's views that cases gin to occur after the fiftieth year and attain a ximum incidence from about the sixtieth year. cording to our figures, the main incidence falls ually on the sixth and seventh decades, though te later years still supply a fair percentage. The es given in Table A are those at which patients ught advice. In order to arrive at a truer indication the age of onset, one must deduct, in each case, t time elapsing between the first appearance of mptoms and the first examination at out-patients. is gives us a new Table B.

Table B.

Ages at onset of symptoms.			History of gonorrhœa.
50–60 years	11 cases	42 %	6 cases.
60–70 „	10 „	39 %	1 case.
70–80 „	5 „	19 %	1 „

is rearrangement shows that most of the subjects prostatism begin their troubles between the ages 0 and 60. There is no way of knowing the duration degree of prostatic hypertrophy in the pre-symptotic period, but it must be considerable, since some he prostates removed must have taken a fair time ttain their final proportions. Several investigators e tried to find at what age the anatomical changes stituting hypertrophy begin. Motz and Péréarnau[5] mined a series of 61 subjects of all ages for adenomata of the prostate, though none of the cases sen had shown any symptoms of hypertrophy ing life. They found 30 instances of prostatic ertrophy, occurring at the following ages :—

Between 45 and 50 years of age	20 %.
„ 50 and 60 „ „	29 %.
„ 60 and 70 „ „	50 %.
„ 70 and 90 „ „	79 %.

Sin and Burckhardt[6] did post-mortem examinations of he prostate of 300 cases, none of whom had shown an sign of prostatic hypertrophy during life. They reported the following findings :—

Cases Showing Hypertrophy of Prostate.

Ages 35–40	13 %.	Ages 60–70	56 %.
„ 40–50	25 %.	„ 70–80	50 %.
„ 50–60	31 %.	„ 80–90	54 %.

T se figures would seem to show that after 60 years of age half the male population have some degree of h ertrophy of the prostate, though only a proportion of hese show symptoms.

urther, it can be seen that the lesions begin ier than is generally believed. Our youngest case w aged 53, but many younger have been recorded. M ion[7] has removed a voluminous prostate, which h caused four years of retention, from a man of 4 Another of his patients was aged 23, and he speaks of a case of Mudd's, a negro aged 17, who showed a large hypertrophy, verified by microscopic examination. Kenneth Walker,[8] in his book on the "Enlarged Prostate," records two of his own cases in men aged 42 and 43 respectively.

History of Gonorrhœa and Sexual Function.

Judging by the patients' statements, the only criteria, it seems that gonorrhœa has some definite influence in precipitating hypertrophy. Table B, of ages at onset of symptoms, shows that 6 out of the 11 cases of hypertrophy in the youngest class of patient volunteered a history of gonorrhœa, and these six form 75 per cent. of the total numbers with a history of venereal disease. Chronic inflammation, and especially gonorrhœa, was one of the first factors incriminated in the ætiology of enlarged prostate, but the association was difficult to prove. Wichmann[9] searched for inflammatory changes but found them only occasionally (in 5 out of 25 cases). Gotzl,[10] investigating the histories of previous inflammations in 334 cases of hypertrophy, found that only 30 per cent. had had gonorrhœa—figures which come very near to our own findings of 8 cases in 26. The most, then, that can be imputed to gonorrhœa is a precipitant action. Hypertrophy, in subjects with a history of gonorrhœa, appears at an earlier age than in healthy subjects.

The sexual functions were investigated by questioning the patients as to their inclinations for coitus, the frequency and character of erections, and their powers of ejaculation. It was found that, speaking generally, the patients showed no change at all as a result of operation; that is, a patient who was leading a sexually active life before the operation found his activity practically unimpaired by it. Erections were just as strong and ejaculation just as forceful as before, but a small number (six) were definitely affected adversely. These results run contrary to those of Marion,[11] who said "Undoubtedly ejaculation is lost in every case." Debout d'Estrées[12] has explained Marion's results by saying that the seminal fluid is ejaculated into the prostatic cavity. It is very doubtful if this happens. As we have seen in our patients, ejaculation was unaffected by operation. The prostatic cavity of which d'Estrées speaks exists only rarely; the posterior urethra is restored to normal by the reappearance of the prostate. Our cases also throw some light upon the part played by the testes in the ætiology of prostatic hypertrophy. Lydston[13] attributed hypertrophy to the onset of genital activity and stated that, after the twentieth year, few men have a normal prostate. MacEwan[14] thought that the testes exerted a regulating effect on the development of the prostate by their secretion. If there is senile atrophy of the testes, this regulation ceases and the prostate develops abnormally. Paul[15] held the same views, and compared the influence of the testicle on the prostate with that of the ovary on the breast. Rovsing,[16] believing that the prostatic secretion stimulated the vitality and motility of spermatozoa, thought that prostatic hypertrophy was a reflex compensation for senile degeneration of the testis. Unfortunately for most of these views, the prostatic hypertrophy is an adenoma, and not a true hypertrophy with hyperfunction. As may be seen from our cases, the state of the testis bears no relation to the state of the prostate, whether we regard hypertrophy as an adenoma or not. In some of our cases the sexual functions had ceased for as long as ten years before operation, in others it was as vigorous as ever.

Symptoms.

Frequency.—Although frequency of micturition has long been stressed as one of the most important and constant features of enlarging prostate, it is difficult to account for this symptom. It has been suggested that the enlargement stretches the smooth-muscle vesical sphincter, makes it patulous, and allows urine to trickle into the posterior urethra, thus giving rise to the desire for micturition. This view does not

account, however, for the frequency associated with the ball-valve type of enlargement—namely, the small prostatic uvula which causes but little stretching. In later stages, however, the frequency may be explained mainly as a result of the cystitis which is so frequently established. Without going further into possible causations, it may be admitted that nocturnal frequency is always present. In many cases there is also frequency of micturition during the day, although this feature is less likely to be noticed by the patient, who is much more worried and impressed by the necessity of having to rise to micturate at night. In our series every case but one volunteered a history of increased frequency both by day and by night. In the one exception the notes do not mention frequency at all. In 11 cases the nocturnal frequency was cured by operation—that is, it was reduced to a single occasion at most. In almost all the other cases there was marked improvement. This alleviation of what is perhaps the most distressing symptom of enlarged prostate is one of the greatest benefits accruing from the operation, which reduces the nocturnal frequency to bearable limits and allows the patient to get some undisturbed rest.

Stream.—The stream in all cases, where notes were made concerning it, except one, was poor both in force and volume, but whether diminished as a result of atonicity and weakness of the bladder, or as a result of prostatic obstruction, it was almost always greatly improved by operation. In one or two cases it was undoubtedly worse afterwards—for example, Case 4, in whom it is interesting to note also that he has developed marked enlargement of the left lobe of his prostate since operation.

Pain.—Preoperative pain was not a marked feature of the series. This falls into line with the findings of other observers. Under this heading several symptoms have been included. Some patients complained of a vague perineal discomfort, some of lumbago, and others of suprapubic discomfort. In some cases the chief complaint was one of urgency rather than of pain; discomfort occurred if they held their water too long. Often pain was present only at the onset of micturition.

It has not been thought necessary to classify such a variety of pain, which, in any case, only affected about half the cases. In all instances but one (Case 4) it was relieved by operation.

Hæmaturia.—Spontaneous hæmaturia was rare, and occurred in only three cases.

Difficulty of Micturition.—This section includes some of the symptoms considered under the heading "Stream." Patients vary in the meaning they attach to the word. Difficulty for some proves to be increased straining in order to start or maintain micturition; for others, it is delay before the beginning of the flow, lessened flow during the act or the longer time taken at each micturition, no matter how small. For most of them, however, it meant delay and straining at the onset of micturition, and 13 of our patients complained of this, while there were many other complaints of slight delay at onset but without straining. In every case the symptom was abolished by operation.

Incontinence.—As might be expected, incontinence was not a feature of the cases. Indeed it is difficult to see why there should be incontinence at all, as long as the external sphincter is intact, and provided that the bladder is not distended to overflowing. The sole instance of incontinence in this series was post-operative in a patient of 83. (Case 20.)

Retention of Urine.—In six cases acute retention was the trouble that brought the patient for treatment, but in each of these six there was a previous history of nocturnal frequency, or of change in the character of the stream, or both. In one case (Case 26) the patient had had retention over a period of two months, occurring one year before the attack which brought him to out-patients. We can conclude that retention is one of the most frequent accidents of hypertrophied prostate, and that it is often th condition which forces the patient to seek treatmen

Rectal Examination.—In 21 of our cases there is record that rectal examination was made befor operation. Definite prostatic enlargement was note in 20 of these. In the remaining cases there is n note whether such examination was made or no In five cases there was obvious enlargement aft operation of one or other prostatic lobe as felt p rectum. These cases are indicated by two or mo plus signs in the table. A single plus sign mea that the lobe was present and palpable but n enlarged. In three cases no trace of the prosta could be felt. It is interesting to note that Marion states: "Clinically, also, it would appear tha even though the adenoma is removed, the prosta remains. In many prostatectomised patients rect examination will reveal masses which have all th characteristics of normal prostatic lobes."

Cystoscopy.—Our series was strikingly free from ar abnormality on cystoscopic examination. In 11 cas nothing abnormal was found, and seven of the had been subjected to cystoscopy before operatio when enlargement of the prostate was noted in eve case, trabeculation of the bladder in four instance and marked cystitis in one. At the post-operati examination two cases showed some trabeculatio Both had been cystoscoped previous to operatio but no record had been made of the presence absence of trabeculæ. Five cases in our post-operati series showed intravesical enlargement of the glan This would point to a recurrence of the adenoma in these cases. The absence of intravesical proje tion in the remaining cases does not negative t re-formation of the prostate itself, but simply reve the absence of adenomata.

Reappearance of the Prostate.

Of the 19 patients examined with the urethroscop only two cases still showed total absence of th prostate. In all other cases one or both lobes we present, sometimes normal, sometimes increased size. In one case there was some definite degree obstruction. In the greater percentage of cases th prostate reappeared after suprapubic prostatectom This lends great support to the view that hype trophy of the prostate is really periurethral in origi Naked-eye examination of specimens removed operation shows that the term "hypertrophy scarcely fits the facts. Hypertrophy of an orga consists of an increase in its volume while the orga retains its normal structure. In the type of prosta termed "hypertrophied," however, the increas volume is due to the addition of neoplastic mass Every specimen of "hypertrophy" shows on secti "spheroidal bodies," consisting of a varying numb of rounded nodules, which are easily enucleated fro a bed of compressed fibromuscular tissue. The spheroidal bodies are made up essentially of glandul acini with but little connective tissue. Some a cystic, and more rarely the smooth muscle conte may be so great that they appear as veritable aden myomata. According to Marion,[18] in certain cas of early adenomatous change these spheroidal bodi may be seen inside a smooth circularly-dispos muscle capsule which can only be the unstriat vesical sphincter. It seems well proven that t essential lesion is the presence of adenomata.

Many authorities have maintained that the increa of glandular tissue is not a real multiplication glandular acini, but simply an enlargement of pr existing glandular spaces. This dilatation is said be the result of duct occlusion by newly form fibrous tissue, following round-celled infiltratio The primary lesion is held to be a chronic inflamm tion, with a secondary enlargement of the glan If the sclerosis involves many small ducts the proce is general, while if it involves one or two large duc the enlargement is localised. Undoubtedly one c find inflammatory foci in certain cases, but the pro that inflammation does not play the most importa

part lies in the fact that often no inflammatory foci can be found in hypertrophy. The specimens on which the conclusions were based may have included many cases of chronic prostatitis without true hypertrophy.

If we admit that the change is essentially an adenomatous one, we may ask ourselves if the adenomata arise from the prostate itself. According to Marion,[19] Rokitanski in 1861 mentioned the possibility that the nodules may develop from the periurethral glands, and independently of the prostate. In 1902, Albarran and Motz,[20] in their "Anatomy of the Hypertrophied Prostate," described two types of median lobe occurring in hypertrophy, one which develops from that part of the prostate in front of the ejaculatory ducts, and another arising from the periurethral glands near the neck of the bladder. Motz and Péréarnau[21] went so far as to conclude that "Hypertrophy of the prostate springs solely from the central periurethral glands and from the stroma surrounding them. The prostate takes no part in the formation of the neoplastic masses; it simply undergoes an atrophy, more or less pronounced." Tandler and Zuckerkandl,[22] however, gave a prostatic origin to the adenoma and stated that all prostatic hypertrophy arises only from that part of the prostate between the urethra and the ejaculatory ducts. Lendorf,[23] after many examinations of prostates removed from subjects ranging from the fœtus to the senile, makes the dogmatic statement that hypertrophy never originates in the prostate, but invariably arises from the periurethral glands. The same conclusion was reached by Papin and Verliac[24] after an examination of almost 200 specimens, embryological or removed at operation or autopsy. They reached the conclusion that hypertrophy of the prostate is an affection, not of the prostate, but of the posterior urethra. It is a process giving birth to suburethral glands, a process which is cut short during the development of the embryo but which is resumed as the prostate atrophies. Histologically, it is easy to demonstrate that such an origin is possible. In a horizontal section of a normal prostate one can see two kinds of glands: (*a*) central submucous glands inside the ring of smooth muscle in this region; (*b*) peripheral glands outside the smooth muscle ring.

The submucous glands (*a*) can be found inside the muscle ring, from the neck of the bladder down to the membranous region. They are the periurethral glands, and just below the bladder neck, but above the verumontanum they form two well-developed groups laterally on either side in the submucosa. There is also a group extending down the anterior wall of the urethra. The peripheral glands (*b*) lying outside the smooth musole ring are the proper prostatic glands, and constitute four groups. There is an almond-shaped group on either side of the urethra, but more posteriorly. A third group lies between these two lobes and between the urethra and the ejaculatory ducts. These form the middle lobe. Finally, there is the posterior lobe, a fourth group between the lateral lobes but behind and below the ejaculatory ducts.

An adenoma may arise in any of these groups of glands, periurethral or prostatic. Marion[25] states that if a section is made at autopsy of the tissue between the prostatic neoplasm and the rectum there is a fibromuscular capsule behind the neoplasm which separates it from compressed and atrophied glandular tissue, and which can be nothing else but the prostate which has been pushed back. Cuthbert Wallace,[26] in 1902, demonstrated the presence of prostatic tissue in the capsule surrounding the adenoma. "If microscopic sections are made from a part of the 'capsule,' that appears entirely fibrous to the naked eye, it will be found that such a section contains glandular elements either in the form of slightly altered alveoli or of long slit-like cavities containing epithelium." Chirié[27] records similar findings at post-mortem examinations after recent prostatectomies. He writes: "Beneath the capsule, recognisable by its vessels and nerves, one can see a thin layer of prostatic tissue." Moreover, Freudenberg[28] reports that in three cases after prostatectomy he has found prostatic glandular tissue in several places in the wall of the cavity.

The conclusion may therefore be drawn that the adenoma which is termed "hypertrophy of the prostate" develops by pushing back the gland itself usually posteriorly, and the affection, as Motz and Péréarnau[21] said, instead of constituting a hypertrophy of the gland is characterised rather by atrophy. It may be seen, then, that the tendency is to regard prostatic hypertrophy as an adenomatous change affecting the periurethral glands and growing at the expense of the prostate. We summarise here the evidence in support of this view.

(*a*) The facility of enucleation which is a characteristic of adenomyomata.

(*b*) Enucleation respects the ejaculatory ducts. If the adenoma arose in the prostate, a large proportion of prostatectomies should involve the more outlying parts of the gland and lead to tearing of the ducts traversing the gland.

(*c*) The possibility of finding the compressed prostate after the so-called prostatectomy.

(*d*) The infrequency of recurrence of obstruction owing to total removal of the urethra with its submucous glands. If the adenoma were prostatic in origin, the atrophied prostatic tissue left in the wall of the cavity should give rise to more adenomata in a greater number of instances.

(*e*) The fact that, although the lateral lobes of the true prostate lie really behind the urethra, in hypertrophy they are in intimate relationship with its lateral walls.

(*f*) The adenomata are always in close relation with the urethra and never grow exclusively towards the rectum as they might be expected, at least occasionally to do, if they were derived from the centre of a true prostatic lobe.

(*g*) There is practically no proof that the prostate itself gives rise to the neoplastic masses.

It is easy, then, to understand why recurrence of obstruction is so rare in our series, while the prostate itself reappears in the majority of the subjects examined. As stated above, the complete removal of the periurethral glands with the urethral mucosa ensures against recurrence of adenomata and, therefore, of obstruction, while the presence of the prostatic remains in the wall of the cavity equally ensures the reappearance of the prostate itself. Freudenberg states recently that he once operated for removal of a second prostate, and that after suprapubic enucleation nodules can often be felt remaining in the cavity. If these are not removed recurrence can follow. He advises that the lining of the cavity—that is, the wall containing the true prostate—should be dissected away after removal of the prostate.

Four specimens were recently shown at the Royal Society of Medicine, one each by Sir John Thomson Walker, Mr. Swift Joly, Mr. Sidney MacDonald, and Mr. Girling Ball. All of these were apparently prostate glands in varying stages of hypertrophy although the patients had been previously operated on for a similar condition. Girling Ball's case is referred to by Kenneth Walker[29] in his monograph on the "Enlarged Prostate." Speaking here of recurrence Walker says:—

"Adhering to the walls of the prostatic cavity will always be found small masses of prostatic tissue, since the operation of enucleation can never be regarded as a complete removal of the prostate. If the enucleation has been imperfectly performed, the quantity of prostatic tissue left behind may be sufficiently great to cause a recurrence of symptoms by their subsequent growth. Even when the operation has been skilfully carried out, cases occur in which the growth of residual prostatic tissue is sufficiently great to necessitate a second prostatectomy. Mr. Girling Ball records a case in which he performed a suprapubic prostatectomy twice on the same patient, an interval of 12 years intervening between the two operations. The prostatic mass removed at the second operation was as large as that removed previously, both specimens being in St. Bartholomew's Hospital Museum. Recurrence, however, is of extreme rarity, provided the removal in the first instance has been complete."

Kenneth Walker is here referring to recurrence of obstruction—a very exceptional event. According to our findings, however, reappearance of the prostate itself is the rule, but this, unlike the periurethral glands, rarely gives rise to adenomata, and therefore seldom causes obstruction.

The question of recurrence has an important bearing on the surgical technique of prostatectomy. It is impossible by the suprapubic operation to dissect away the whole of the wall of the cavity to ensure complete removal of the prostatic tissue. Indeed it is almost certainly not desirable to do so. Recurrence of obstruction can only be due to one of three causes. First, the tags of mucosa at the edge separating the bladder from the prostatic cavity may unite and form a diaphragm across the neck of the bladder. This is so easily dealt with later by diathermy that it should not be allowed to prolong, by five minutes if further dissection, the already severe operation of prostatectomy. Secondly, the prostatic "hypertrophy" may recur. As we have seen, recurrence of obstruction due to the formation of new adenomata is exceedingly rare, because the whole of the anterior and lateral walls of the urethra and the posterior wall above the verumontanum are thoroughly stripped, ringing away the submucous glands. Prostatic tissue is left in every case, and it is doubtful if any amount of prolongation of the operation will remove it. The third cause of recurrence of obstructive symptoms is also the commonest—namely, massive fibrosis of the original prostatic cavity—and this, we think, most commonly follows attempts to dissect the cavity and its edges clean. Sometimes it results from the enucleation of the normal prostate along with a small adenoma. If the adenoma is small though it may cause obstruction but still leave the prostate in very much its original condition. To remove a prostate of this type requires scissors dissection, because the true fascial capsule is now invaded by the surgeon; such a prostate is usually referred to as "fibrous." Many of these would be better left *in situ*.

If this view of the periurethral origin of prostatic adenomata be correct, it would seem that no benefits can accrue from the exposure of these enfeebled and aged subjects, after the shock of enucleation, to a prolonged dissection of the prostatic cavity. Simple and speedy operations give the best results.

Clinical and Laboratory Notes.

A CASE OF MENINGEAL ENDOTHELIOMA OF THE INTERPEDUNCULAR SPACE SIMULATING PITUITARY TUMOUR.

BY C. D. SHAPLAND, M.B., B.S. LOND.,
LATE RESIDENT PHYSICIAN, RUTHIN CASTLE.

THE following case presents much that is of interest, both from the view of diagnosis and treatment.

The patient, a man aged 49, general manager of a large iron and steel company, was admitted to Ruthin Castle in January, 1926, with the following history. Enjoyed good health until October, 1918, when there was a severe attack of so-called influenza accompanied by violent pain in the head behind the eyes. After recovery remained pretty well until April, 1920, when his sight began to fail; an ophthalmic surgeon at this time diagnosed pituitary enlargement. For the next two years he improved under thyroid and pituitary extract by the mouth. In July, 1922, he was admitted to Duff House, Banff, where a diagnosis was made of pituitary tumour with pressure on the right optic tract. The basal metabolic rate (B.M.R.) was 86 per cent. (normal= 100 per cent.), a carbohydrate-tolerance test was found to be normal, a blood count showed 11,800 white cells per c.mm. with 50 per cent. of small lymphocytes, and an X ray of the head revealed a pituitary fossa with an ill-defined floor and the sphenoidal sinus apparently invaded from above and behind. Under medical treatment the patient remained fairly well and was able to work hard until the summer of 1925, when his health definitely became worse. He easily became fatigued, could no longer concentrate mentally, suffered abnormally from cold, his sight got worse, and constipation became very troublesome. During the last week before admission his memory for recent events became bad, there were evening rises of temperature up to 101° F., and he suffered from five attacks characterised by twitching of the face, movements of both arms, involuntary passage of urine, and unconsciousness for two or more hours.

On examination he showed the following signs of dyspituitarism. The skin was glossy, thin, and finely wrinkled round the temples, and at times sweated profusely; the hair of the scalp was scanty and the pubic hair showed the female distribution; the B.M.R. was low—66 per cent.—and a carbohydrate-tolerance test gave a curve suggestive of increased tolerance to sugar; there was slight but definite enlargement of both hands and feet; he had an acromegalic type of face, and had undergone a loss of sexual power.

On examination of the nervous system visual acuity was found to be diminished, there being a complete left lateral homonymous hemianopia with a positive hemiopic pupillary reaction (Wernicke). The right fundus oculi showed an abnormally pale disc with fine arteries and slightly congested veins—in other words, an early primary optic atrophy; the left fundus showed similar, though less advanced, changes. Tendon jerks were brisk in both upper and lower extremities, though more definitely so on the left, and on this side there was an extensor plantar response. Abdominal reflexes were sluggish on the left side.

The pulse-rate was slow—namely, 64 beats per minute—and the blood pressure low—108/84 mm. Hg. A blood count showed 8100 white cells per c.mm. with a moderate relative lymphocytosis, but was otherwise normal. The blood Wassermann was negative.

Radiological examination of the head revealed a pituitary fossa with an ill-defined floor, the posterior clinoid processes rarefied and displaced backwards, and numerous calcareous plaques above and behind the dorsum sellæ. The sphenoidal sinus was dense and appeared to be invaded and compressed from above; the maxillary antra and frontal sinuses were clear.

Discussion on Diagnosis.

A provisional diagnosis of mixed adenoma of the pituitary was made. Points in favour of this diagnosis were the symptoms of dyspituitarism and the radiological evidence of distortion of the pituitary fossa. On the other hand, it is much more usual for an adenoma of the pituitary to enlarge primarily upwards and forwards and so cause pressure on the optic chiasma with a resulting bitemporal defect in the visual fields. In this case, however, pressure signs from the first were on the right optic tract and the later signs of pyramidal tract involvement—

namely, the increased tendon jerks, sluggish abdominal reflexes, and extensor response on the left side pointed to a backward extension of the growth into the interpeduncular space with pressure on the right peduncle. Points in favour of meningeal endothelioma were the great amount of bony destruction revealed by the X rays—a simple adenoma of the pituitary usually producing a more or less globular expansion of the sella turcica—the presence of calcareous plaques, and the clinical evidence of backward extension.

The signs of gradually increasing intracranial pressure—namely, the epileptiform seizures, the mental change, the impairment of vision, and the frequent headaches—made active interference absolutely necessary. The question of operative treatment or deep X ray therapy was considered, and operation was finally decided upon on the grounds that the exact nature of the tumour could only be guessed at, and it was thought right to give the patient the chance of the condition being a simple cyst.

Operation.

This was performed by Mr. Percy Sargent, the patient being under intratracheal ether.

An osteoplastic flap was turned down in the right frontal region and the right frontal lobe exposed. Intracranial pressure was high. The dura was incised and the convolutions of the brain were seen to be flattened. The frontal lobe was gently lifted up from the orbital plate of the frontal bone, but the intracranial tension was too high to gain the necessary access; a lumbar puncture was therefore performed and a test-tube full of blood-stained cerebro-spinal fluid withdrawn. The right frontal lobe was again gently lifted and the optic chiasma and right optic nerve came into view. There were numerous arachnoidal adhesions round the right optic foramen. A small bluish body appeared immediately to the medial side of the right optic nerve. On further lifting the frontal lobe a large portion of growth, about the size of a cherry, gradually extruded to the right side of the right optic tract. The capsule of the growth was incised and a large quantity of soft, grumous, semi-diffluent matter sucked away. As far as could be made out the growth extended at least one and a half inches backwards from its anterior extremity, and also crossed the middle line. The diaphragma sellæ appeared to be intact. The osteoplastic flap was replaced and the operation completed. Patient stood the operation well and the pulse-rate was 84, regular, and good volume at its close. Unfortunately, however, the patient never regained consciousness and died suddenly about three and a half hours later.

Section of a portion of growth showed the latter to be a malignant meningeal endothelioma (Greenfield).

This case is of interest in that a tumour arising extrinsically to the pituitary and its fossa nevertheless produced typical symptoms of pituitary dysfunction—a phenomenon no doubt due to local pressure on, and vascular changes in, the pituitary body. The exacerbation of symptoms which led to operative treatment was probably occasioned by a temporary swelling of the tumour, which was undergoing degenerative changes.

My thanks are due to Mr. Percy Sargent and Dr. E. I. Spriggs for permission to publish this case.

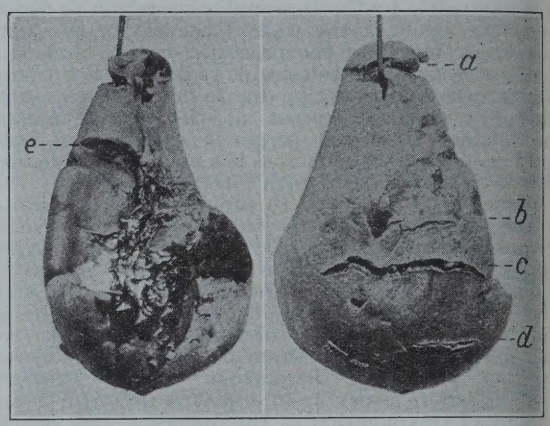
A CASE OF RUPTURED MALARIAL SPLEEN: SPLENECTOMY WITH RECOVERY.

BY D. LAURENCE TATE, F.R.C.S. EDIN.,
DISTRICT MEDICAL OFFICER, MONTEGO BAY, JAMAICA.

THE following case may be of interest, as most ruptured malarial spleens in Jamaica cause sudden death and a coroner's inquest, and especially as this case was not seen till 30 hours after the rupture.

The patient was a native male adult, aged 37 years. He had been well known to me for several years as a malaria patient with a large spleen. On August 22nd, 1926, at about 11 A.M., he was thrown from a "buggy" and fell, chiefly on the abdomen. Shortly after the accident he vomited twice and during the following night suffered from severe abdominal pains; he passed two blood-stained stools. He was not seen by me till 6 P.M., August 23rd (30 hours after the accident) and was then in a collapsed condition with a pulse of 120. He complained of severe pain all over the abdomen, worse in the hypogastrium and right iliac fossa. The abdomen was rigid and very tender all over, with dullness in the flanks; the superficial reflexes could not be made out positively.

He was removed to hospital and at 7 P.M. the abdomen was opened through a right rectus incision. The peritoneal cavity was full of blood, for the most part dark and clotted but showing also evidence of profuse recent bleeding. The



Malarial spleen showing ruptures *a*, *b*, *c*, *d* on outer surface, and *e* on inner surface.

abdominal organs were quickly examined and the spleen was found ruptured (ruptures A and C being easily felt). This wound was rapidly closed with forceps and an upper left rectus incision made, but as there was some difficulty in delivering the spleen an incision was made along the margin of the lower ribs to meet it. The spleen was then delivered easily, the pedicle clamped and ligated, and the organ removed. At this stage the patient's condition was so poor that, after quickly cleansing the peritoneal cavity both wounds were quickly sutured in single layers and a drainage-tube inserted into the pelvic cavity (removed 48 hours).

Salines were given continuously during the operation and rectal salines for the next 24 hours (I find it difficult to give blood transfusions in the island on account of the prevalence of syphilis and the aversion of natives to act as donors). The wounds showed superficial sepsis for a few days; otherwise convalescence was uninterrupted.

The man was discharged in four weeks apparently quite well and has not returned to me with an attack of malaria but reported four weeks later with an attack of gonorrhœa.

The weight of the spleen on the morning after operation was 16 oz. Ruptures A, B, C, D were on the outer surface; rupture E was on the inner surface. Unfortunately rupture A was torn a little deeper by the photographer.

Conclusions.

1. The hæmorrhage must have stopped temporarily but was renewed by the jolting over four miles of rough road to hospital. 2. Evidently no large vessel was implicated. 3. The two blood-stained stools may have been due to a contusion of the bowel which did not appear on the peritoneal surface, or to the common practice of the peasantry of dosing themselves with calomel to remove "bruised blood." 4. The lack of shock was striking. I have often observed this among natives.

DOUBLE LESIONS OF THE STOMACH AND DUODENUM.

BY GEORGE VILVANDRÉ, M.R.C.S. ENG.,
ASSISTANT RADIOLOGIST TO THE LONDON HOSPITAL.

THE presence of two ulcers in the same patient, one gastric and one duodenal, is very liable to cause error when the diagnosis is based solely on clinical grounds. Under careful X ray examination the condition may, however, be accurately diagnosed. Such a patient may give a history of acid eructations, epigastric pain, not severe, but coming on two hours after food; and of waking up at night with pain

at any time between 12.30 and 6 A.M. He may state definitely that food relieves pain so that a duodenal ulcer may be suspected. Another patient, after suffering from such symptoms for many years, may complain, in addition, of rare attacks of vomiting, and seek medical aid on his friends' advice because of the brown colour of the vomits. There may or may not be loss of appetite, loss of weight, and some anæmia. The clinical picture is still further obscured by the duration of the symptoms, the patient stating that he has had indigestion for years and been careless about his meal-times. According to the predominance of some of the symptoms, the diagnosis made will be that of duodenal or gastric ulcer or possibly pyloric carcinoma.

I have seen half a dozen cases lately where such a history was given, with slight variations, and in these I have found a double lesion, one gastric and one duodenal. One patient showed, under X rays, a dilated stomach with the great curvature quite a hand's breadth below the iliac crest and a penetrating ulcer the size of a threepenny piece on the small curvature. There was also a duodenal ulcer. Judging from the onset of symptoms the gastric ulcer had, in all probability, been present for 10–12 years, during which time the patient had been treated for "indigestion," and the duodenal lesion had been active some four years. Another patient gave a history of 23 years of pain, one and a half hours after meals, without waking up at night. There was no vomiting nor hæmatemesis, and melæna was not noticed. There may be periodical attacks lasting a few weeks with intervals of five or six months.

I believe that an accurate diagnosis of double lesions of the stomach and duodenum before operation is of great importance. I have lately seen a few cases where operation had been performed for duodenal ulcer and within two years an X ray examination showed a large penetrating gastric ulcer on the small curvature. This was in no sense a jejunal ulcer. I have little doubt that these patients were not only suffering from a duodenal ulcer at the time of operation, but also had an ulcer on the small curvature of the stomach. This result is obviously unfortunate, as unless a second operation is performed there is a possibility of malignant degeneration of the gastric ulcer. In one case the patient had had a duodenal ulcer sutured after acute perforation. The ulcer was described as quite small; no gastro-jejunostomy was done. Nine years elapsed and recently when I X rayed him I found evidence of an active duodenal ulcer and a large penetrating gastric ulcer.

Summary.

Double lesions of the stomach and duodenum may occur, and their presence obscures the clinical diagnosis. In operation for duodenal ulcer a gastric lesion should always be sought or excluded. Gastro-jejunostomy for a duodenal lesion does not necessarily cure or prevent the formation of a gastric ulcer.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF LARYNGOLOGY.

EXHIBITION OF CASES AND SPECIMENS.

AT a meeting of this Section held on Nov. 4th, the incoming President, Mr. H. S. BARWELL, was conducted and a number of cases were shown.

Mr. T. B. LAYTON showed a laryngeal case which the Section had inspected in May of this year. When first seen on March 31st, 1927, the patient, a man of 65, had a six months' history of hoarseness and showed irregular swelling of the whole length of the right cord. He improved considerably after dental treatment but in May still showed slight swelling and two small white spots like heaped epithelium. These at operation proved to be flaky pus and there was no evidence of malignancy. At the present time the appearances were practically what they had been at the end of March.

The PRESIDENT remarked that when he saw the case in May he thought it probably malignant and advised an exploratory thyrotomy. It was, he said, far better to explore than to allow a cancer to advance beyond reach of treatment.

Sir STCLAIR THOMSON said that several of his cases of pachydermia had turned out to be tuberculous.

Mr. NORMAN BARNETT reported that the elderly man with a growth of the hard palate shown at the summer meeting had died from general toxæmia, but his growth had been proved to be non-malignant.

Laryngo-fissure for Intrinsic Carcinoma.

Sir STCLAIR THOMSON presented four medical men who had had laryngo-fissures 2¼, 3, 4½, and 5½ years previously for malignant disease. All were in active practice. He emphasised the importance of taking the growth out in one piece and showed sketches illustrating the operation. The piece should embrace the anterior commissure.

CASE 1.—Aged 40. In March, 1922, had sudden onset of hoarseness after singing. Right cord found invaded by an irregular, mammillated growth with necrotic, white, ulcerating points over the centre. After two months' voice-rest the voice was better but the cord was still ulcerated. Biopsy did not confirm the clinical diagnosis of malignancy. At laryngo-fissure in May a typical squamous-celled carcinoma was removed, together with a good part of the right ala. The patient was well within a week and his wound closed in ten days. He reported himself as "very fit but not noisy" now.

CASE 2.—Aged 52. Had been hoarse for two months when first seen in 1923. The right cord showed a characteristic, cupped, grey infiltration of the anterior half, while the rest of it showed a red, beefy infiltration. A squamous epithelioma was removed and the wound closed in 20 days.

CASE 3.—Aged 56. Had been husky six months when seen in 1924. An irregular, knobby, whitish, slightly cupped, abraded thickening was found on the front half of the right cord. After two months of voice-rest and observation the appearance got worse and movement of the right cord began to flag. The laryngo-fissure in December was followed by a hæmorrhage and the tracheotomy-tube was found to have slipped out; a "Jumbo" tube should have been used. The patient returned home in 12 days. After three years he smoked two or three pipes daily and was in excellent health.

CASE 4.—Aged 62. Had had ten months' huskiness before he was seen in 1925. A portion of a papilloma was removed for examination. The right cord had a superficial, whitish, moist, irregular, papilloma-like infiltration. After the usual operation he was out of bed on the second day and home on the eleventh. The wound closed within a week. The growth was a typical squamous-celled carcinoma.

The speaker called attention to the following points:—

Clinical Features.—The lesion was limited in all cases to the cord, and did not invade the subglottic area or the anterior commissure. The anterior half of the cord was invaded in all cases, in some entirely and in all chiefly. No impairment of mobility.

Diagnosis.—Apart from naked-eye appearances and general considerations, the diagnosis was confirmed by the exclusion of tubercle and lues, and the results of voice-rest and observation—two months in two cases.

Operation.—This occupied 50 to 60 minutes; but as much as 52 minutes (Case 1) had been occupied in arresting hæmorrhage before the patient was removed from the table.

Thyroid Ala.—Removed in all cases, allowing a free approach, more perfect excision, and better control of bleeding. Quicker healing: no stenosis. A further justification was the pathologist's demonstration that the growth, even in the limited and favourable cases, extends deeply into the muscular tissue.

Tracheotomy.—Performed in all cases, thus securing complete protection against descent of blood, mucus, and septic material into the bronchi and facilitating a light, smooth, and satisfactory anæsthesia.

Tracheotomy-tube.—In one case removed at the termination of the operation; in the others left in place till the same evening (i.e., seven to eight hours).

Bleeding.—Guarded against by careful preoperative precautions—abstinence from alcohol and tobacco; careful diet; 48 hours' rest in bed beforehand; smooth anæsthesia and intratracheal and intralaryngeal injection of cocaine.

Postoperative Hæmorrhage.—This had occurred in one case and the source was *outside* the laryngo-trachea. This emphasised the importance of arresting all venous and thyroid-gland oozing before opening the trachea.

Convalescence.—No shock. Wide-open windows night and day. Sitting posture. Up to 24 hours; out in three or four days; and in no case more than three weeks in the home.

Simplifications.—No alkaloid (morphia, atropine, heroin, &c.) at any time. No intratracheal packing or applications (e.g., cautery, Whitehead's varnish, antiseptic powders, diathermy, &c.). No artificial feeding.

Results.—Rapid recovery. Good general health, improved as a rule by increased attention to rules of hygiene and avoidance of fatigue and vitiated air. A voice generally as good as before operation and sufficient to carry on satisfactorily the duties of medical practice. Lasting cure.

The subglottic case, said Sir StClair Thomson, was most difficult to diagnose; laryngo-fissure, however, was often quite successful. To be certain of having completely removed the growth he always had three sections cut; the anterior and posterior parts of the removed piece should be entirely free of cancer cells. Even this was not quite reliable, as malignant cells were apt to go deep. He agreed with Mr. Lionel Colledge that the cases absolutely suitable for laryngo-fissure were those with a mobile cord and without subglottic growth. Others were on the borderline.

Mr. E. WATSON-WILLIAMS mentioned hemilaryngectomy as a measure for dealing with borderline cases.

Mr. H. TILLEY described three cases of recurrence; in one of them laryngo-fissure had been performed, and 15 years later a small nodule appeared on the scar. After its removal another nodule grew and eventually the whole larynx became a mass of epithelioma. In the second case 19 years elapsed before the recurrence was heralded by intense stridor; there was also a growth in this man's prostate. In the third case a growth appeared in the opposite cord after 15 years. It was therefore not wholly true to speak of "cure" five years after operation. He was reminded of the dictum of an old teacher: "Once cancer always cancer," if the patient lived long enough for the recurrence to have its chance.

Mr. F. O'MALLEY spoke of excellent results without removal of the thyroid ala.

Mr. L. COLLEDGE did not approve of hemilaryngectomy; if half the larynx were removed the skin must be turned in to replace the lost epithelium and the skin-flap was apt to collapse. Patients were little better off than after laryngectomy.

Sir STCLAIR THOMSON referred to two hemilaryngectomy cases of his own. Both had to wear a tracheotomy-tube permanently, but they had a voice. It was more fatal than the complete operation, but had the advantage of saving part of the cord. He had had a case two and a half years ago with recurrence on the opposite cord; there had not been any recurrence so far after a second laryngo-fissure. He had also known two cases of recurrence in the local glands and one in the mediastinum.

Mr. COLLEDGE showed a case in which laryngectomy had been performed four years ago on account of recurrence of epithelioma after laryngo-fissure, and another in which lateral pharyngotomy had been performed to remove an epithelioma of the epiglottis. Both showed excellent results. The artificial larynx was a "Tapia."

The PRESIDENT expressed surprise that more patients did not use some form of artificial larynx.

Mr. W. S. SYME said he had found external laryngotomy very useful.

Mr. COLLEDGE replied that in this case the operation had started as a laryngectomy, but on finding that it was not necessary to remove more than the epiglottis, it had developed into a subhyoid pharyngotomy. This involved cutting both superior laryngeal nerves, and the lateral approach was therefore preferable, besides giving a better view. Moreover, the function of the pharynx was much better, in spite of some dysphagia, than after a subhyoid laryngotomy.

Cardiospasm and Achalasia.

Mr. H. BELL TAWSE showed a boy of 11 who had suffered for two years from vomiting on going to bed. The Wassermann was negative. X ray showed obstruction at the lower end of the œsophagus with great dilatation above. There were several calcareous glands at the hilus and a dense shadow from the manubrium to the third interspace, possibly that of an enlarged thymus. A second case was a girl of 10 who had had difficulty in swallowing when 2 years old. After bronchitis in her fourth year it got worse and was diagnosed as enlarged thymus. At 7 the attacks became very severe and the child ran about crying for air. In some attacks consciousness was lost; during them thick mucus collected and was vomited, causing relief. A transthoracic operation revealed enormous dilatation of the œsophagus and was followed by death. There was no autopsy. The X ray photograph showed good diaphragmatic movement and no delay in passage of food to the stomach. A shadow of uniform opacity extended from the first to the last rib, encroaching on the right lung from behind. The only explanation not ruled out by the clinical condition was a dermoid cyst growing from the posterior mediastinum. It was hard to believe that that shadow was entirely caused by the dilated œsophagus.

Mr. Tawse showed for comparison X rays of another case with a kink in the œsophagus. For treatment he relied on Hurst's mercury tube.

Mr. W. M. MOLLISON showed a photograph of an S-shaped kink in the middle of the œsophagus of a woman who had symptoms of achalasia. He hoped to do an œsophagostomy.

Mr. E. DAVIS said he had seen several similar cases. One patient came up every six months for dilatation with Hurst's mercury tube, and the œsophagus was gradually getting larger. Dilatation relieved but did not cure.

Mr. TILLEY showed a man of 58, a tinsmith who had had achalasia with vomiting for 18 months before admission to hospital last August, when he was emaciated and very weak. He had had an uncomfortable feeling in the gullet and "lump in the throat" since 1915. He was treated with Hurst's mercury tubes, which he soon learned to pass himself; he had no further vomiting after the first dilatation. He spent 11 days in hospital and now passed a bougie once a week, ate anything he likes, and had put on 14 lb. in weight.

Replying to a question, he said that he preferred the mercury tube to the bougie because the former was much less likely to "hitch" and the patient could use it himself. It seemed simple and satisfactory. He had never had the courage to try mechanical dilatation with an expanding steel instrument. Referring to Mr. Tawse's case, he had only once seen a large dermoid producing dysphagia and stridor; this case might possibly be similar.

The PRESIDENT did not think Mr. Tawse's first case was one of achalasia, but of something more obscure.

Foreign Body in the Larynx.

Mr. M. VLASTO showed a girl of 19 who had swallowed an open safety-pin on July 10th. X ray showed it in the larynx, the safety guard peeping through the rima glottidis. There was very slight dysphonia. As the pin could not be dislodged by gentle movements the patient was taken from the dark room to the theatre for an operation. A laryngotomy failed to reveal the pin and splitting the thyroid fared no better. A further endoscopy showed that it had slipped down the right bronchus during transit to the theatre. It was removed without difficulty.

Mr. H. KISCH showed a case of

Sphenoidal Sinusitis.

The patient was a man of 36 who had had intense frontal pain periodically since 1916. There was some

catarrh and a grossly deflected septum. X ray revealed opacity of the right sphenoidal sinus, which could not be lavaged because of the septum. At a submucous resection a culture was taken which showed pure growth of *B. mucosus capsulatus*. Complete cure followed.

Mr. WATSON-WILLIAMS said that this man had had marked loss of memory and of concentration, and that he had a most difficult and intractable temper. His mentality had been so altered that he had contemplated suicide. Suicide was not infrequently due to sinus infection, but those cases were never investigated post mortem. He asked members to communicate examples to the *Journal of Mental Science*. Mental symptoms made or marred the welfare of the patient and his environment, and might clear up with removal of the sepsis.

Mr. J. ADAM referred to two cases of sphenoidal sinusitis, both of which had been under the care of alienists. The condition might be the initial stage of a frontal lobe abscess.

Mr. VLASTO said it was very common to get a complete change of mentality after operating on a case of sinusitis, single or multiple.

Mr. L. POWELL showed a case of

Post-cricoid Carcinoma Successfully Treated by Diathermy.

The patient was a woman of 56 who had had catarrh of the throat for a year. For three months she had had dysphagia, loss of weight, and at night a slight cough, bringing up watery fluid. A large edunculated irregular tumour obscured the larynx and extended forward to the epiglottis. At the operation in April a Davis gag and no other form of suspension was used. A week later the patient was again examined and doubtful spots touched with the diathermy point. Six months later she continued well and had gained 3 lb.

Sir J. DUNDAS-GRANT demonstrated a simple ligature applicator for tonsillar vessels,[1] a glass or metal tube to facilitate Coakley's slip knot, and showed a case of

Severe Asthma Relieved by Submucous Resection.

The patient, a man of 50, had for many years been obliged to get up every night and sit at a table in order to breathe. After removal of a very deflected septum his attacks entirely disappeared, as did his spasmodic.

Miss ELEANOR LOWRY showed a woman of 46 who had been treated for

Lupus Erythematosus.

She had noticed deformity of the nose two weeks before. There were lupoid nodules all over the nose and both cheeks, large sequestræ in the nose, and a palatal perforation. The Wassermann reaction was positive. After an injection of novarsenobillon the lupoid condition rapidly cleared up, and after three injections it had completely disappeared.

Mr. W. MOLLISON showed a case of fixation of the left vocal cord due to a blow on the neck. There had been no sign of hæmatoma of the cord at the time.

SECTION OF ANÆSTHETICS.

A MEETING of this Section was held on Nov. 4th, when Dr. CECIL HUGHES, the President, opened a discussion on the

Present Position of Spinal Anæsthesia.

It was now 30 years, he said, since the first experiments had been made in the production of analgesia by injection of drugs. In 1885 an attempt had been made to alleviate spinal caries by injecting cocaine into the spinal canal extradurally, and intradural injection had soon followed; but the poisonous aftereffects of cocaine had not encouraged the investigators to persevere. The isolation of other chemical bodies, however, had brought about renewed activity and injection of these anæsthetics was almost universal. The mortality of spinal anæsthesia was very low, and the deaths recorded as having followed its use were mostly due to the serious condition of the patient at the time, to an unwise choice of the anæsthetic, or to an overdose having been given. There was every prospect that, with the exercise of sounder judgment and a more careful technique based on longer experience, the mortality from the spinal injection of stovaine per se would diminish to the vanishing point. Spinal injection could be utilised to produce analgesia of the whole body—including the thorax, head, and neck—or (as was more usual) for operations on the abdomen and lower limbs. As regards the drugs employed, the use of general anæsthesia as an adjuvant, and the technique, the practice varied a good deal in different countries. Glucose was not used so often now as formerly, as it seemed adversely to affect the respiratory mechanism. Preliminary narcotics were always given in quantities varying from a sedative dose to one that induced twilight sleep. The President had found no records of serious after-effects apart from fatalities from overdosage—minor sequelæ were infrequent and lasted only a short time. The method should not be used for a patient with very low blood pressure, but in normal people the danger of a fall in blood pressure after the injection was not great when due precautions were observed. One paper, reviewing 6000 cases of spinal analgesia at Los Angeles, recorded six deaths, four of them said to have been surgically inevitable, two following an overdose. Few of the ill-effects lasted longer than three days. Another series of 410 mentioned nausea occurring in 2 per cent., hysteria in 3 per cent., and vomiting in three patients; there were no post-operative sequelæ. In a series of 20,000 cases, 90 per cent. of the operations were below the diaphragm and were carried out under spinal anæsthesia. Some of the operations which had been abandoned under general anæsthesia were resumed under spinal analgesia and carried to a successful issue.

In the President's experience, spinal analgesia was unsurpassed in acute abdominal conditions. No other method gave such quick and perfect relaxation; functional disturbance was minimal, peristalsis was promoted, and tympanites relieved. In his own most recent 500 cases the average fall of blood pressure was 30 per cent.; the fall was greater in those with high pressure than in normal people. His custom was to give a preliminary dose of gr. 1/6 morphia and gr. 1/10 atropine; in the vast majority of patients morphia was both helpful and beneficial. He used 5 per cent. stovaine, 10 per cent. sodium benzoate, and caffeine citrate in distilled water, and this combination gave him less anxiety about blood pressure. The point of injection was between the third and fourth spines, and light general anæsthesia was induced by means of C.E. (chloroform and ether) mixture, inhaled three minutes after starting the injections. When using stovaine, tactile sensation might remain though pain was abolished. He kept his needles sterilised in absolute alcohol, and before use he rinsed them with stovaine. This was certainly the anæsthetic of choice for urological cases, in which it was particularly necessary that there should be little shock and that the after-effects should be minimal. He had not employed it in cases where there was low blood pressure, myocardial degeneration, or spinal trouble. The fall of blood pressure was greater in prostatectomy than in most other operations; it occurred soon after the gland had been removed. Almost invariably the pressure recovered to the extent of 10 to 20 per cent. He had not employed oxygen as a routine. In his own series there were no fatalities, and in less than 1 per cent. was a restorative or any antishock medication used. Manipulations involving insult to nerves, which without nerve-blocking would have produced shock, did not do so. With spinal anæsthesia constant blood pressure readings should be taken, but the pulse-rate was the most important criterion. When the Trendelenburg posture had been employed the patient's normal position should not be restored for two or three hours—that is to say, the head should be kept lower than the body. Nausea, headache, and

[1] THE LANCET, Oct. 8th, p. 760.

vomiting had been rare in his cases. Absence of headache he attributed to the use of a very fine needle; it should be noted that headache occurred after simple lumbar puncture in 5 per cent. of cases. Psychical causes played an important part in producing after-effects in a conscious patient, and these could only be averted by employing light general anæsthesia. He had had two cases of paresis of the external ocular rectus, in one of which the condition lasted several weeks. These were difficult to explain, seeing that the analgesia was limited to the lower part of the canal. Possibly they were associated with a general fall of blood pressure. There had also been a few cases of stiffness of neck muscles after the injection, but this was only transitory. When undesirable after-effects —such as bronchitis, abdominal distension, vomiting, and jaundice—followed operation under a general anæsthetic, it was difficult to say that the anæsthetic was the sole cause; but spinal anæsthesia did not offer the same loopholes, and sequelæ had to be attributed to the method.

Chloroform, said the President, had perhaps had its day for routine work. The relative mortality of spinal anæsthesia and gas and oxygen could only be ascertained by publication of failures as well as successes. Even now he was convinced that the use of the spinal method in difficult pelvic operations—especially urological and gynæcological—had considerably lowered the post-operative mortality.

Discussion.

Mr. P. LOCKHART-MUMMERY said that from the point of view of the condition of the patient three or four days after operation ether and chloroform were unsatisfactory; there was sickness, a lowered vitality, and lack of appetite for the food which was so much needed to assist the repair of the tissues. Some patients were sick even after spinal anæsthesia, but the speaker was prepared to accept the risk, and he was a great believer in spinal anæsthesia at present. Regional anæsthesia was also a valuable method, but was still on its trial. He did not see the need for it in operations below the level of the umbilicus. When accidents such as paralysis occurred he thought they must be due to faulty technique, careless use of the needle, injection of the wrong substance, or sepsis. The only troubles he had seen after spinal anæsthesia were a lowering of the blood pressure, one case of diplopia, and one of paralysis of the external rectus, which passed off in six weeks. He strongly emphasised the need for keeping the head and chest of the patient lower than the rest of the body; he did not allow spinal anæsthesia to be used unless there were facilities for moving the patient on a trolley. Strychnine should always be kept handy, as on two occasions in his experience the phrenic nerve had been affected, though the patients survived. He thought it was wise always to use the same solution—the one to which the administrator was accustomed. He did not notice any idiosyncrasies to stovaine.

Mr. G. GORDON-TAYLOR said that in his view the cases most suitable for spinal analgesia were those requiring operations on the lower abdomen or lower limbs. He also used it when general constitutional disease made it undesirable to give a general anæsthetic and when the operation to be undertaken promised to be specially difficult—e.g., removal of carcinoma of the pelvic colon. When shock was expected, and when the period of anæsthesia had to be long, he preferred splanchnic anæsthesia, coupled with light general anæsthesia. He still thought, however, that for certain operations in the neck there was no anæsthetic so good as chloroform, and he would be sorry if that drug were to disappear from the anæsthetist's armamentarium.

Mr. H. M. PAGE considered that the induction of light general anæsthesia before making the injection added greatly to the patient's comfort. He had not met any bad sequelæ from the method. For prostatic cases, even when the Trendelenburg posture was employed, he had cut the injection dose down to 0·03 c.cm. coupled with very slight general anæsthesia. He agreed about the benefit of using a very fine needle for the injection, especially from the point of view of subsequent headache, and he liked to have the patient in the sloping position from the time of the injection. Before giving the spinal injection he examined the patient's reflexes as a routine. He was not favourably inclined towards chloroform.

Dr. Z. MENNELL disapproved of the view, apparently held by some, that for operations below the nipple spinal anæsthesia was the one for choice. Various surgeons agreed that headache was a common sequel sometimes of such severity that it was difficult to deal with; and neurologists recognised a condition following the use of this method which they knew as "stovaine tabes." Another objection was the very definite fall of blood pressure after its use. He was accustomed to use camphor or strychnine after making the puncture. His objection to the method was the uncertainty of its action; he did not feel he could accurately assess the dose necessary for the best result in a given case. He had not noticed great loss of appetite in patients after the ordinary administration of ether.

Dr. C. F. HADFIELD said he had given stovaine injections for large gynæcological operations for 12 years, and he had not seen the bad after-effects which had been spoken of. He did not know of a case of the so-called stovaine tabes. But he thought that the mortality from spinal anæsthesia had been greater than that from ether or other anæsthetics of the same class. He was a believer in the value of inducing twilight sleep. Headache was less liable to occur after a prolonged operation than after a short one.

Mr. D. H. EVANS described a case in which he gave 0·75 c.cm. stovaine to a woman weighing 10 st. She was all right for 15 minutes, after which she began to gasp. Artificial respiration was attempted, but soon no air could be got into her lungs and she died, the pulse failing within half a minute. There must have been more than cardiac weakness, possibly some toxic action. He used 10 per cent. stovaine B in saline.

Mr. HOWARD JONES said that years ago he had abandoned stovaine for novocaine, with which he was able to secure perfect relaxation.

Dr. H. E. G. BOYLE said that one death from stovaine had occurred in his practice, and he knew of three others. He believed the mortality from it exceeded that of other anæsthetics. He used gas oxygen, ether endotracheally and they gave as good results, and could be regulated to a nicety.

Mr. ASHLEY DALY thought every patient who had spinal anæsthesia should be kept in bed for several days.

Mr. R. J. CLAUSEN spoke of two cases which were given spinal anæsthesia and operated upon before the Wassermann report was received, which proved to be positive. Both had neurological symptoms accompanied by paralysis of the rectum, lasting respectively three and four months. In some cases requiring operations on the prostate and perineum he thought spinal anæsthesia was better than either ether, or gas and oxygen, or ether and chloroform. But he thought there was a better anæsthesia than spinal—namely, a sacral injection, with caudal block.

Dr. J. BLOMFIELD spoke of a patient who had had spinal anæsthesia for a Wertheim's hysterectomy and had afterwards been paralysed in both lower limbs for a week with incontinence of urine. Careful selection of cases for the spinal method should be made; it was not suitable for all and sundry. Induction of twilight sleep saved the patient distress.

Dr. W. V. HUGHES said that he used twilight sleep before putting in the injection needle. Headache was attributed to moving the patient after operation.

The PRESIDENT, in the course of his reply, said that he only encountered one case of headache after spinal anæsthesia in nine months or a year. Headache was sometimes due, he felt sure, to psychical shock, and this was avoided by light general anæsthesia. It seemed agreed that headaches were prevented by keeping the patient comfortably in bed after the operation. He knew nothing of the "stovaine tabes" which had been mentioned. If it really was an entity it ought to be investigated.

HUNTERIAN SOCIETY.

AT a meeting of this Society held on Nov. 7th, with Mr. MORTIMER WOOLF, the President, in the chair, Dr. JAMES NEAL opened a discussion on the

LEGAL PERILS OF THE DOCTOR.

He thought it strange that the medical man, who had legal obligations above those of the ordinary citizen, should have no instruction in law such as was given to students of accountancy and banking. Even the well-informed and careful medical man was always liable to false charges of negligence, incompetence, or misconduct. All that was necessary was for an insane, hysterical, or aggrieved person to get the idea that he ought to have made a more rapid recovery or had a better result from treatment. The temptation to pay compensation rather than face an action was very great, but every case successfully contested decreased the liability of others to the same oppression. After explaining the implications of the term professional "negligence," Mr. Neal pointed out the danger that juries might mulct a doctor in damages even when it had been proved that treatment had followed the most approved modern methods. It was always possible to criticise any line of treatment and to find a medical witness who would have done differently, and juries would condemn a treatment about which they knew nothing. Routine precautions must be adopted, especially in the matter of examining women patients, and taking X ray photographs. Ordinary examinations might be construed as criminal assault, and failure to examine might constitute negligence. Medical certification bristled with perils, for a doctor was liable for any injury caused by deficiencies in his certificate, or for libel if it had been signed unreasonably or without due care. Doctors ought to be protected from having to pay the costs of a successful defence for certifying under the Lunacy Act. Section 330 of the Act had not given the protection expected of it, though the position would be improved if the recommendations of the Royal Commission became law. Medical assessors, as suggested by the British Medical Association, might help to protect the doctor, but could not prevent actions for libel. Modified, though not absolute, protection should be given to certificates, as it was to the statements of a witness on oath. The Dangerous Drugs Act limited the right of a doctor to prescribe what drugs he conscientiously believed to be necessary. The new tribunal, with power to deprive a medical man of his right to use dangerous drugs, created an impossible situation.

Dr. Neal quoted examples of the danger of performing operations without the explicit consent of the patient and warned doctors against inadvertent breaches of confidence, such as divulging information to a solicitor. An appeal from the police to assist in tracing the mother of an abandoned infant should be disregarded; doctors were not detectives. While the doctor should try to persuade the victim of criminal abortion to inform the authorities, he should beware of giving information himself. In cases of suicide or suicidal intent the chief consideration was the welfare of the patient, and the doctor was bound to take steps to prevent the repetition of an attempt. The obligation of professional secrecy was waived when disclosure was enjoined by Act of Parliament or ordered by the Court; the doctor whose conscience forbade him to speak under these circumstances must take the consequences. If breach of confidence were necessary to prevent a crime, avert serious danger, or safeguard the patient's interests, the medical man must be prepared to justify it afterwards.

Failure to Find a Remedy.

Earl RUSSELL admitted that doctors suffered hardship, but saw no remedy. Nor had the Royal Commission been able to find any solution. No society of medical men desired that doctors should be exempt if they had been reckless or negligent The Bateman case had shocked him profoundly; that was not the sort of thing from which doctors wished to be protected. He deprecated a partial knowledge of the law as more likely to lead doctors astray than otherwise; they would do better to follow the simple rule of honestly doing the best they could for the patient. The law was not unreasonable in this matter, though he admitted that the conflict of medical evidence, inevitable since medicine could never be an exact science, might lead to confusion in the minds of the jury. Doctors, however, very seldom did themselves justice in the witness-box, and they might well benefit from lessons in giving evidence or in answering questions. The injustice of having to pay costs when the plaintiff proved to be a man of straw was common to every member of the community, and it was difficult to see where such costs were to come from except out of the defendant's pocket. He could not conceive any sensible jury declaring that a patient ought to be brought round from an anæsthetic in order to obtain his consent to a second operation for a procedure which could and should have been carried out at the time. Absolute protection was afforded to the witness on oath in the interests of the administration of justice; it could not be given to the doctor certifying under the Lunacy Act, for there were doctors who were careless, reckless, or even not quite bona fide in certifying. A certificate of infectious disease was one of the few instances where the doctor had to guarantee his diagnosis. Juries tended to be hard on doctors, he admitted, but he did not see what medical assessors were to do.

A Legal Peril of the Medical Witness.

Sir HERBERT WATERHOUSE expressed his general agreement with Dr. Neal and said that one of the greatest legal perils of the doctor was the treatment meted out to him in the witness-box by members of his own profession. He had known many cases utterly lacking in substance, cases the defence had thought could be laughed out of court, but he had never known the other side unable to find medical witnesses. These were not always minor members of the profession, and there was a great tendency for certain names to appear time after time. This state of affairs was discreditable to the profession; it was terrible that there should be doctors willing and anxious to give evidence against their professional brethren, and evidence, moreover, which would never be received by members of their own profession if they were on the jury. Referring to the "notorious" Hume-Spry case, he asked if any member of the audience would be prepared to swear an affidavit that he, the speaker, had been sane three years ago. The thing was absolutely monstrous. Yet three such affidavits had forced the Court of Appeal to allow a trial, twice previously disallowed, which cost the Medical Defence Union £5000.

Referring to the danger which threatened the doctor from his association with nurses, he said he wished the public could realise the grievous stare of anxiety the surgeon was in under many circumstances when he committed that crime so terrible, to the laity, of "leaving a sponge inside." He instanced a midnight operation by candle light which he had once had to perform in a farmhouse on a pulseless woman with a perforated duodenal ulcer. He had urged the strange nurse repeatedly to be responsible for the sponges, but when at the end he asked for her final count she assured him they were all there, though he held one concealed in his hand.

Blackmail.

To illustrate the danger of what he would term minor "blackmail," he instanced the man with the hysterical wife who ran a bill with the doctor for a year or so, and when the account was presented threatened an action for negligence if it were pressed. He repeated exactly the same thing with another doctor. Neither doctor was a member of a defence

union and both said: "What is the good of going to court? Let it slide." That was cowardice to their profession. The doctor accused of negligence was bound to follow up the matter for the sake of his profession. If no woman should be examined without the presence of a third party, then a fortiori no anæsthetic should ever be given to a woman alone. Even gas given for a dentist might produce illusions of assault in the mind of a highly-strung patient.

One thing went beyond medical etiquette, and that was the duty owed to the public. If a young girl was engaged to a man known to have florid syphilis, the speaker would advise the doctor to do all in his power to stop the marriage. His last word was: Beware of the telephone. He knew case after case where private messages had been tapped, and quoted one where a patient had left him saying he was about to lunch at a certain club. Half an hour later a voice on the telephone said it was Mr. So-and-So speaking from that club, and asking that a copy of the prescription might be sent to him at that address. As Sir Herbert Waterhouse in this case had given no prescription the fraud was obvious, and the voice proved to be that of a private detective set to watch the patient by his wife.

Mr. RAYNER GODDARD, speaking as a "G.P. of the law," pointed out the "legal peril" of the sub-pœna, which dragged doctors away from their work to give evidence, perhaps in some accident case where they had happened to treat a victim now claiming damages. The great complaint of the doctor was not that he was liable to be brought to court for negligence, but that scientific matters would there be dealt with before unscientific minds. Every profession was open to actions for negligence and the proportion of doctors who ever came to court was remarkably small; there was no peril that need haunt them. The only remedy was insurance. Every profession had members of whom it was ashamed, but he could not agree that it should be impossible for doctors to testify against their professional brethren. It was the bounden duty of a medical man who honestly believed that a brother practitioner had committed a grave wrong on a fellow citizen to further the ends of justice and give evidence against him. He held no brief for juries, and recent legislation seemed to tend more and more to reduce rather than to extend the jurisdiction of the jury. Accused persons accepted this readily enough, save for "old lags" who knew their best chance was to go before a jury. Nevertheless, he did not think the profession would be well advised to get their cases withdrawn from the consideration of a jury or that juries were prone to be antagonistic to doctors whose professional reputation was at stake.

A Judicial Tribunal to Give the Lunacy Certificate.

In the matter of the lunacy certificate, he quoted the considered judgment of Lord Justice Scrutton in the case of Everett *v.* Griffiths. His lordship had there expressed the opinion that there was no contractual duty between the doctor (a Poor-law officer) and the patient, and that the doctor's certificate was not the effective cause of detention. This raised most important questions to which no final answer had been given. In the absence of contractual liability there could be no negligence. Another important point was the position of the doctor who refused to certify and "negligently" declared to be sane a person who next day committed an antisocial act. The trend of opinion in the House of Lords seemed to be that the doctor who examined a patient in any circumstances did owe a duty to the patient to be careful. The law allowed protection to judges and magistrates and those who performed public duties in order that the duties might be fearlessly done. There ought to be some such protection for the doctor signing the lunacy certificate. He suggested that no person should be finally committed to an asylum until he had been reported on by a "judicial tribunal" of three medical men, and that no doctor should be proceeded against if he had referred the case to that tribunal in good faith.

Dr. TEMPLE GREY agreed that doctors themselves were to blame if actions for malpraxis succeeded, but the lunacy certificate was a very different matter. A judicial authority willing to take the responsibility of the certificate must be found; there was no lack of men with double qualifications. The anomaly of the "effective cause" of detention could be rectified as easily as had the problem of jurisdiction in territorial waters after the case of Rex *v.* Keen. The responsibility of the judicial authority ought to be clearly settled and a real legal peril removed from doctors who were not free to avoid it, for doctors as a class were far too aware of their duties as citizens ever to refuse to certify.

Dr. PERCY SMITH disagreed with Mr. Goddard's suggestion of a panel of three doctors, on account of the extra trouble to relatives in acute cases of mental breakdown. The Lunacy Act regarded statements on a certificate as equivalent to a statement on oath; why should they not be so regarded in court? The so-called "protection" clause in the Act was a reversal of the ordinary principle that the onus of proof should be on the prosecution. He advocated the "Provisional Treatment Order," and pointed out that by far the majority of recovered patients were grateful. Actions were brought by those without insight.—Dr. NEAL briefly replied.

NEWCASTLE AND NORTHERN COUNTIES MEDICAL SOCIETY.

A MEETING of this Society was held at Newcastle on Nov. 3rd, Dr. STANLEY RAW presiding. Dr. J. C. SPENCE read a paper on the

Liver and Pernicious Anæmia,

in which he reported the results of cases treated in the Royal Victoria Infirmary, Newcastle, by the liver diet of Minot and Murphy. He first paid tribute to the manner in which these American workers had approached and pursued their researches. It was a beautiful example of the application of the scientific method to a clinical problem, and had yielded a result which would rank as one of the most important discoveries in medicine in recent years. This discovery had a greater significance than the mere provision of a cure for pernicious anæmia, for it would probably throw fresh light on physiological processes, both in the liver and in the generation of blood cells.

Dr. Spence described the results of using a liver diet or an effective liver extract in 20 successive cases of pernicious anæmia, which had been treated in the Newcastle Infirmary since the beginning of the year and contrasted these with ten control cases on older methods of treatment. The results, he said, had merely confirmed those of Minot and Murphy. In 19 cases there had been a prompt and rapid rise of red blood cells with quick improvement of the patient's general condition. One case only had failed to respond, for a reason which was not yet clear. In the 19 successful cases the red cells had risen to more than 4½ millions within two months and in some cases had reached 6 millions. Referring to the tendency to relapse when an adequate amount of liver was not taken continuously, Dr. Spence said that the response seemed to depend on the amount of liver taken, and that harm might result from taking too much liver after the stage of cure had been reached. This was illustrated by three cases in which the patient had eaten a pound of liver a day for three months after the blood cells had been restored to their normal level. In each of these the red cells had reached 6 millions. Two of the patients had developed acute gout, whilst the third had developed the more serious complication of venous thrombosis with œdema of the legs. This suggested that it was necessary to control the dosage of the liver by frequent blood counts, and he thought that in practice it would be found that once a cure had been established it would suffice in most cases to maintain the patient's condition by giving about 8 oz. of liver three times a week. The danger of provoking gout would probably

be overcome when treatment by liver feeding was replaced by the giving of an effective liver extract. Following the lines laid down by Cohn, an extract had been prepared in the Chemical Pathology Department of the infirmary and had been used with success in three cases; 20 to 25 g. of this extract had been given daily to these patients, and had produced a reticulocyte crisis, rise of red cells, and improvement of the symptoms within seven days of its use. The sudden appearance of reticulated red cells in the blood stream was one of the most interesting and important signs of the restoration of the bone-marrow to its normal state of function. A clinical sign which was almost as dramatic was the rapid disappearance of the tongue symptoms. These had disappeared in one severe case before any rise in blood cells had taken place, and before the height of the reticulocyte crisis had been reached.

Dr. Spence discussed the bearing of Minot and Murphy's work on the explanation of the pathogenesis of pernicious anæmia. It appeared, he said, to dispose of the prevalent theory that the condition was due to a hæmolytic process, and probably hæmolytic streptococci in the gut had nothing to do with the disease.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

A MEETING of this Section was held on Oct. 28th, Dr. G. E. NESBITT, the President, in the chair.

Dr. H. F. MOORE and Dr. A. R. J. DUNGAN contributed a paper on the

Minot-Murphy Diet in Treatment of Pernicious Anæmia.

They described five cases which had been treated with liver for periods ranging from seven to twelve months. In all of them clinical improvement had started within a few days of beginning the treatment, and there had been marked and rapid increase in the number of red blood corpuscles and the hæmoglobin; in four of the cases the leucocytes had tended to increase in number and the colour-index to diminish, whilst anisocytosis and poikilocytosis had disappeared. Complete remissions with practically normal blood-counts had been induced in all the patients, and so far they had persisted. Glossitis had cleared up and the patients had been able to resume their normal lives. Dr. Moore and Dr. Dungan concluded that the Minot-Murphy diet treatment of pernicious anæmia was astonishingly successful in inducing a remission. Dr. Dungan explained that the colour-indices had been calculated on the classical basis, but by reason of the marked sex- and age-variations in both red cell-count and hæmoglobin-content, he doubted whether this was altogether rational. The success of the diet might possibly be evidence against the theory that pernicious anæmia was due to a chronic intoxication, since it seemed unlikely that a marrow undergoing a continuous slow poisoning would recover its function so dramatically after the administration of a comparatively simple chemical substance. On the other hand, the anæmia might be due to damage caused by a previous infection, such as was believed to occur in the pancreas in diabetes. In some of the cases of Minot and Murphy, the actual volume of the red corpuscles had increased more than fourfold under treatment, and if studies in blood volume had been possible in the present series they would presumably have shown a similar result.

Dr. L. ABRAHAMSON said that he had treated three cases by the method. In the first case of pernicious anæmia the patient had been so ill on admission to hospital that he could not tolerate liver or any solid food, and the treatment had not had a fair trial. In the second, a typical case of pernicious anæmia, the patient was admitted to hospital on Sept. 28th, 1927, with a red cell-count of 1,310,000 per c.mm., and a hæmoglobin percentage of 35. After 19 days of liver feeding the red cell-count had increased to close on 4,000,000 per c.mm., and the hæmoglobin to 60 per cent. Improvement in the general symptoms had been dramatic. The increase in reticulocytes described by Minot and Murphy had not been noted in this case. The third case treated was one of severe secondary anæmia and had shown no improvement on liver treatment. Dr. Abrahamson thought that it would be necessary to wait for some years before the results of this treatment could be evaluated; but it was encouraging to read that cases had been followed for over three years without relapse. The liver treatment was an important departure in therapeutics generally, and in pernicious anæmia it was not only a promising method of treatment, but was also likely to clear up the ætiology. He thought that the success of liver feeding argued against the theory of intestinal toxæmia.

Dr. V. M. SYNGE had so far only treated one case, the patient being a woman of 25.

For three months before admission to hospital she had typical symptoms of pernicious anæmia and a typical blood picture. When she was admitted Dr. Synge had not heard of the Minot-Murphy method, and tried ordinary treatment. She was unable to take arsenic by the mouth, but had arsenic injections. Liver treatment was started at the end of last May. After a week there was very marked improvement, and she left hospital healthy and fit, though a little anæmic, at the end of June. She was now in excellent health and was taking liver and hydrochloric acid daily.

In the diagnosis of doubtful cases of pernicious anæmia Dr. Synge thought that the most reliable test was the estimation of bilirubin in the blood. Since he had started using this test he had never found a case of pernicious anæmia in which it had not held good.

Prof. S. S. PRINGLE said that perhaps the new knowledge of the value of liver feeding in pernicious anæmia would later throw light on blood-formation by the spleen.

Prof. J. W. BIGGER asked whether liver treatment had been tried in such forms of secondary anæmia as bothriocephalus anæmia.

Prof. J. M. O'CONNOR said that he could hardly regard liver treatment as being successful owing to its action on the bone-marrow. If the results were due to bone-marrow stimulation a distinct change might be expected in the white cell-count.

Dr. A. R. PARSONS pointed out that the real difficulty was to treat pernicious anæmia in the relapse. No one could yet say that the results of liver treatment were going to be permanent, but it was encouraging to note that Minot had got nearly as good results in third attacks as he had in first attacks.

Dr. R. A. Q. O'MEARA said that the microscopic picture of the bone-marrow in pernicious anæmia was one not of destruction but of very active regeneration. In favour of the toxic origin of the disease were the peculiar cases in which pernicious anæmia started with achlorhydria which was followed by subacute combined degeneration and later by symptoms of anæmia. He agreed with Dr. Synge that the van den Bergh reaction gave valuable information as to the nature of the anæmia, and he thought it would be interesting to see the effect of liver treatment on the bilirubin content of the blood.

Dr. H. QUINLAN, referring to a patient of his who had at first been unable to take liver, said that in cases like this a liver extract or powder would be a great improvement. He had treated two other cases; one of them had greatly improved, but the other had not.

Dr. E. T. FREEMAN asked if any alteration had been noticed in the blood pressure of patients who had taken large quantities of liver.

Dr. MOORE, in reply, thought that care should be taken for the present about mentioning the word gland until it was found out whether the therapeutic substance was a hormone or not. The literature stated that liver was much more effective if given raw than when cooked. In some cases he had found that the blood pressure had risen, but only slightly, and not more than would be accounted for by the patient's general improvement.

Reviews and Notices of Books.

MEDICO-LEGAL INJURIES.

By ARCHIBALD MCKENDRICK, F.R.C.S. Edin., Medical Referee under Workmen's Compensation Act; Consulting Radiologist to Edinburgh Royal Infirmary. London: Edward Arnold and Co. 1927. Pp. 341. 18s.

THE general scope of this book is indicated in another column. It deals with injuries "arising out of, and in the course of, employment" as defined by the Workmen's Compensation Act. No attempt is made to describe criminal cases; no reference is made to industrial diseases which are by definition the results of "accidents" within the meaning of the Act, and no mention is made of injuries to the special senses.

A long and helpful section is devoted to injuries of the back, where the difficulties of making an accurate diagnosis and prognosis are well known. After an elementary but sufficient description of the anatomy of the spine, we have a clear account of the curves, movements, and supports of the column; we have a description of two types of violence to which the back may be subjected: (1) intrinsic (from muscular action), and (2) extrinsic (from violence applied from without). A heavy lift "may cause strain of the muscles, but it cannot cause damage to the spine itself." If, however, the strain under which the muscles are acting is suddenly released, as when the handle breaks from a heavy weight, then either the opposing muscles may be injured or so much "whip" is imparted to the spine that this may snap. Only two types of extrinsic violence are described at length —falls on the buttocks and overbending of the spine. Fractures of the bodies of the vertebræ are a much more frequent result of these accidents than is generally supposed. Three cases are quoted in which falls on the buttocks have caused fractures of the first or second vertebræ. Each of these patients was able to continue his work at the time, and the fracture was only discovered by X ray examination at some later date. Of overbending of the spine generally it is said that injury to ligaments results amounting "to sprain of spinal joints." Sometimes there is a fracture or fracture dislocation of the vertebræ, but we are told that this "cannot possibly cause damage to the muscles, because the muscles are not actually overstretched even when the spine is bent beyond its normal limits." As a result of overbending the spine backwards, the anterior common ligament may be torn, and an effusion take place in front of the bodies of the vertebræ in the neighbourhood of the injury. Soon after the accident the bone becomes spongy and porous, and casts a faint shadow only on an X ray film, and it may be exceedingly difficult in such cases to make a differential diagnosis between uncomplicated strain and tuberculosis of the spine. The large majority of these cases clear up in time, but two cases are quoted in which tuberculous disease eventually developed at the site of injury. In writing a report on injuries of the back the greatest care must be taken in obtaining an accurate and detailed account of the accident. Often a patient will say that he "ricked his back," when on further questioning the actual injury may prove to have been a compression, strain, or a blow which he thought had "ricked his back." The examination should be conducted in a systematic manner, and the same sequence should be adopted in each case. Very good rules are given for the examination of muscles in cases of back injury. Boarded muscles may exhibit a peculiar sign termed "give" according to the condition which is causing the boarding; the patient is asked to bend forwards, and the examiner places his hand on the boarded muscles and keeps it there for a full minute, and if there is no "give," something radically wrong with the spine may be found—e.g., tuberculosis. If there is a more or less gradual "give" followed by a shorter "give" the muscles themselves are at fault. But if there is no "give" at first and then a somewhat sudden and short "give," and then a longer "give," so on, until the back is fully bent, it may be taken as strong presumptive evidence of malingering. Full instructions are given as to the simplest methods of measuring the movements of the spine, and diagrams are appended to show how little of the movement of bending forward is accomplished by the spine, and how much is due to flexion of the pelvis at the hips. The pitfalls in interpreting X ray films of the spine are explained, and it is noted that the fifth lumbar vertebra is seldom injured, yet owing to the impossibility of obtaining a clear X ray picture of it without the overlapping shadow of the fourth lumbar vertebra or the sacrum, deformities and injuries are constantly being associated with it. "Railway spine" is dealt with in a short paragraph on page 147. Although frequent reference is made to this condition in the text the general reader would find it more convenient if all the particulars were collected under one heading.

In discussing injuries of the head the writer deals for the first time with injuries that have not to be considered with reference to the Workmen's Compensation Acts, for example, bullet wounds. While considering fractures of the skull he advances a new theory on fractures from contrecoup:

> "A person may fall and strike the back of the head on the ground and sustain a fracture, not at the back of the head, but in the front of the skull. Such fractures have hitherto been described as fractures from *contre coup*. A much more likely explanation is that during the fall the chin has come forcibly down against the chest and the violence has been transmitted to the front of the skull through the jaws."

On the difficult subject of pain Mr. McKendrick warns us that the amount of pain which an injured person suffers cannot be accurately gauged—only the patient "knows what he feels." But where there is genuine severe pain or tenderness there are signs which the examiner can appreciate and use as a very rough guide in estimating their degree. Five such signs are described: (1) Haggard appearance; (2) rise in blood pressure when the painful area is pressed; (3) dilatation of the pupil when the painful area is pressed; (4) increase in pulse-rate when the painful area is pressed; (5) boarding of the muscles over the tender area. Sweating and flushing are not included in the list.

Rupture of internal organs and blood-vessels always affords a subject for spirited medico-legal argument. The pathology of these conditions is clearly defined, and the way in which aggravation of an old-standing disease is brought about is explained. Yet in the two cases quoted it is very difficult to understand how the court came to its decision. No mention is made of gastric ulcer caused by trauma, and yet it is a definitely recognisable condition and has, on at least one occasion, been established in the English court. The chapter on hernia is clear and on the whole unbiased, but it starts and finishes with statements which will not pass unchallenged. On page 248 we are told that "the most up-to-date medical opinion is in effect that there is no such thing as traumatic hernia." And on page 254 "Hernia may be aggravated by an accident such as a strain. If this happens the aggravation passes off with the reduction of the hernia." This claim will be absolutely rejected by many. Even allowing the presence of a congenital sac, there can be no reasonable doubt that when a hernia is forced through for the first time, there is definite stretching or tearing of muscle which does not completely recover with the reduction of the hernia, so that a very much smaller strain will in future determine the descent of the hernia.

A book of this description should find its greatest use for reference in particular cases. We expect that it will be constantly produced in court, and for this purpose it is well designed. It is light and of a size that will readily go into a brief bag; moreover, the printing is distinct and the diagrams and illustrations are good. Appendix 3 is a glossary of medical terms

and this, though necessarily incomplete, is extremely useful, the descriptions being short and clear. The writer has had much experience with the Scottish miner and some of the technical terms are not readily understood from the context; a "hutch" is apparently the northern equivalent of a "tram" or "dram." Occasionally Scottish law terms are used—e.g., the "pursuer" is in the English courts known as the "applicant."

This book will be found of equal value to the practitioner, who is occasionally called upon to examine medico-legal cases, as to the responsible laymen for whom it is written.

INTRACRANIAL TUMOURS.

Some Errors in their Diagnosis. By Sir JAMES PURVES-STEWART, K.C.M.G., M.D., F.R.C.P., Senior Physician to Westminster Hospital. London: Humphrey Milford, Oxford University Press. 1927. Pp. 206. 12*s.* 6*d.*

THIS useful and readable little volume is elaborated from the presidential address given by its author to the Neurological Section of the Royal Society of Medicine. It is based on a painstaking survey and analysis of some 253 personal cases of intracranial tumour—an experience amply sufficient to prove fruitful for both accuracy of diagnosis and avoidance of error. A tabulation of the local types encountered in 121 anatomically verified cases reveals tumours of practically every site imaginable, the greater number being cortical (52) and cerebellar (29). Clinical syndromes for the different types are provided by a selection of appropriately illustrative cases. Some pitfalls in diagnosis are exemplified, and some errors candidly commented on. A large number of photographic and other illustrations serve to elucidate the text. With so much material, and where the author has obviously so much more to say, it is perhaps regrettable that statistical survey has not been carried further—e.g., in respect of survival rate, duration, histological type, &c. The clinical histories are full and satisfying, yet they entail careful reading if their significance is to be grasped, and summaries representative of each local type would have been helpful. As it is, the book will be appreciated most by those with comparable experience.

Die chirurgische Behandlung der Gehirntumoren; eine klinische Studie. By Dr. HERBERT OLIVECRONA, Oberarzt of the Surgical Clinic, Seraphimerkrankenhaus, Stockholm. Berlin: Julius Springer. 1927. Pp. 344. Rm.27.

Dr. Olivecrona's fine monograph is based on the complete investigation of some 105 cases of intracranial growth, of which 75 were verified by operation or autopsy. A pathological classification shows them to have been gliomas, 11 meningiomas, and 12 pituitarinomas; rarities (cholesteatoma, angioma, tuberculoma, metastatic tumours) occurred a few times. This classification is followed also from the clinical side; that is to say, a chapter is devoted to the clinical study of glioma, the next to a similar study of the clinical syndromes of meningioma, and so forth. For such an arrangement we have nothing but praise; it is precisely the line of investigation, hitherto largely neglected, that is calculated to prove fertile for both clinician and neuropathologist. To add some indications beforehand of the histological type likely to be met with in a given case for exploration is a consummation often sought in vain; any clues facilitating the search are welcome. For each of his pathological groups the author gives a summary; as an example, he has had 28 cases of supratentorial glioma; clinical diagnosis before operation, operation-mortality, cause of death, relation of this last point to nature of tumour, prognosis, operability, &c., are all examined with conspicuous candour and lucidity. These are precisely the matters on which the conscientious neurologist is ever seeking further light to be thrown, yet few indeed of the writers on cerebral tumours deal with them adequately. Attention is also directed to present-day improvements in technical method (X ray, ventriculography, exploratory puncture) and, of course, a large section is concerned with surgical procedure. Of 85 cases operated on death followed in 34. No less than 15 causes of death are tabulated and scrutinised, post-operative rise of pressure through general cerebral œdema being responsible for 13 of the 34 fatalities. Many other highly instructive summaries are given; as a single example, the frequency of papilloedema, not in varieties of localisation but in the different pathological types of tumour, is examined.

It is gratifying to scan the pages of a monograph so original and so practical in its bearings. It will repay fully a minute perusal.

PERIODIC HEALTH EXAMINATION.

How to Make Periodic Health Examinations. By EUGENE LYMAN FISK, M.D., Medical Director, Life Extension Institute; and J. RAMSER CRAWFORD, M.D., Assistant Director, Life Extension Institute. New York: Macmillan Company. 1927. Pp. 393.

IN 1861 Dr. Horace Dobell urged the institution of a system of periodical examination, and at the present day the principle has many sponsors. For those who retain any doubt as to its practicability the manual before us by Dr. Fisk and Dr. Crawford, both of wide experience in this field, should prove useful. It is the outcome of a smaller book prepared with the assistance of a special committee of the medical staff of the New York Life Extension Institute, and each of the sections dealing with regional examinations now has an introduction supplied by an expert. The preliminaries concerned with history-taking and recording are first described along with a discussion of equipment and routine procedure. Next follow 14 sections on different regions in detail; here the description of the taking of blood pressure (p. 85) and of the nervous system are particularly good. The section on laboratory methods and standards reflects the wholesome attitude to laboratory tests adopted by Dr. Mazyck P. Ravenel. The author of the anonymous final section on "counselling" is to be congratulated on the competent manner in which he handles a difficult subject. The numerous charts given in the appendix are not as terrifying as they appear at first sight. There are some illuminating statistics and a good bibliography and index.

DISEASES OF THE SKIN.

Second edition. By ROBERT W. MACKENNA, M.D., Lecturer in Dermatology, University of Liverpool; Hon. Dermatologist, Royal Infirmary, Liverpool. London: Baillière, Tindall and Cox. 1927. Pp. 452. With 179 illustrations, including 36 in colour. 25*s.*

THE immense subject of eczema is a test of the merits of a text-book on the skin, for it is one which makes the most searching demands on the writer's experience, logic, and literary knowledge. Dr. Mackenna has managed to compress all that it is necessary for the practitioner to remember into 27 pages, which include 10 admirable illustrations of the most typical examples of this protean disease. There is no attempt to dogmatise, and all the theories of causation are considered in very simple terms. It is, however, clear that the author favours an underlying dyscrasia of the skin itself as the most potent factor in production, and in so doing he identifies himself with the most progressive schools of the day. The forms of treatment advised for eczema reveal profound experience of all the difficulties that may arise, and that can largely be prevented by a judicious selection of specific applications in the various stages. The formulæ are simple and not too numerous, and in addition to an outline of therapeutic methods for the disease as a whole there are separate paragraphs for special manifestations in the various parts of the body,

such as the anus, vulva, and breast. The practitioner will probably find this the most useful chapter in the book. An excellent feature of the work as a whole is the free use of tables showing important points in the differential diagnosis of such diseases as dermatitis herpetiformis and pemphigus, erythema nodosum and tuberculous and syphilitic gummata of the legs, psoriasis, and psoriasiform syphilides. These will greatly assist the student. There is an index both of subjects and authors, and the literary references are well chosen and not too numerous. The book has arrived at its second edition in four years, and certainly deserves to be placed among the first three or four English publications of its kind.

THE LIFE OF THE FLY.

The Insect's Homer. With which are interspersed Some Chapters of Autobiography. By J. H. FABRE. Translated by A. T. DE MATTOS. London: Hodder and Stoughton. Pp. 317. 2*s.* 6*d.*

THE title seems to be confused, but the volume is a well-printed and splendidly cheap reprint of Fabre's few essays about diptera, made up with a chapter on caddis-worms and several, which are specially interesting, on his mathematical studies, his visit to Paris to receive the Legion of Honour, and other personal matters. It would be much improved by some simple illustrations, but that is probably impossible at the price.

MEDICINE IN NEW ZEALAND.

Proceedings of the University of Otago Medical School. No. 4, 1927. Edited by D. W. CARMALT JONES, M.D., F.R.C.P. Dunedin: Budget, Ltd.

THIS volume contains 13 papers by members of the Otago Medical School, reprinted from various Australasian journals. The first four comprise Parts III. to VII. of a treatise in preparation by Dr. John Malcolm and others, of the New Zealand Institute, on the food values of New Zealand fish, and deal respectively with the shell-fish pana (*Haliotis iris*), the relation between the fats of the red cod and its food, the vitamin-A content of mutton-bird oil and certain fish oils, and the vitamin content of the tarahiki. The results have a commercial as well as a scientific significance, for they show that the pana is a valuable food of high protein content, that mutton-bird oil is one of the richest natural sources of vitamin A, and that tarahiki, a breakfast ration of which would probably supply an adult's requirements of A, would be in many ways a suitable fish for canning. A fact that constantly appears in these researches is that fish seem to store the fat of their food almost unchanged, and an analysis of it can often be relied on for accurate information about their feeding habits. The last three papers in the collection are devoted to the study of hydatid disease, which is a notifiable disease in New Zealand, and which, besides claiming about a hundred victims every year, causes great loss to the meat-exporting industry. Mr. Roland Fulton, in a survey of 90 cases, gives a death-rate of 23·3 per cent. and a recurrence-rate of 16·6 per cent. The high mortality is due to suppuration, which occurred in 19 cases as a result of late diagnosis, and the danger of leaving cysts behind after operation is much greater in suppurating cases. The problem, therefore, is chiefly one of diagnosis, and Messrs. C. C. Anderson and C. E. Hercus contribute to its solution from the X ray and the laboratory sides respectively. Mr. Anderson also contributes a paper on the X ray examination of the gall-bladder. The remainder of the collection consists of two studies by the editor on the relations of temperature and pulse-rate and on chronic arthritis; papers on pneumococcal peritonitis and ureteral strictures by Mr. J. A. Jenkins, and an account by Dr. Ruth Barclay of an unusual fracture of the elbow-joint. The radiological articles are illustrated by several good skiagrams.

JOURNALS.

JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXX., No. 4. October, 1927.—Healed Tuberculoma of Cerebellum, by M. J. Stewart (Leeds). An old calcified tuberculous mass in the right lobe of the cerebellum, visible by X rays and causing no symptoms.—Large Calcified Tuberculoma of Cerebrum by R. P. Smith (Newcastle). A similar case but with an old history of cerebral symptoms.—Diphtheria Toxoid-Antitoxin Floccules, by A. T. Glenny and C. G. Pope (Beckenham). The Ramon precipitate from mixtures of toxoid and antitoxin is as good an antigen for active immunisation as that from toxin and antitoxin and has the great advantage of being free from any danger from excess of toxin.—A Comparison of the English, German, and Japanese Systems of Classification of Dysentery Bacilli, by D. Kalic (London). A useful synonymy is arrived at by agglutination and absorption tests.—Tumours of the Rabbit, by C. J. Polson (Manchester). Fourteen tumours are described, mostly carcinoma of uterus.—Effects of Coal Dust on the Silicotic Lung, by S. L. Cummins (Cardiff). Coal dust is usually harmless to the lungs, and, indeed, may actually stimulate the phagocytic mechanism to remove other particles more completely. But if the lymphatics have been blocked by previous silicosis, any considerable further exposure to coal dust may be very detrimental.—The Activity of the Thyroid Gland in Relation to the Staining Reactions of the Colloid, by Evelyn E. Hewer (London). An attempt to correlate the activity of the gland with the empirical staining reactions of the colloid.—Agglutination of Typhoid and Dysentery Organisms by the Sera of Mental Hospital Patients, by F. A. Pickworth (Birmingham). About a quarter of the patients admitted to asylums show some agglutination with enteric bacilli; the author does not adduce any evidence that normal people do not do the same. After repeated dose of T.A.B. vaccine different patients show very different agglutination responses to the different bacilli.—Hypernephroma of Atypical Structure, by J. Gray (Aberdeen). An example which, by its papilliferous structure in parts, reveals the real nature of these tumours—i.e., renal carcinoma.—Thrombo-angeitis Obliterans, by R. O. Girdwood (Aberdeen). A careful description of the anatomy and histology in a non-Jewish case.—The Production of Experimental Atheroma with Cholesterol, by R. W. Scarff (London). Atheroma can easily be produced in rabbits by adding cholesterol to their normal diet. Some months after feeding is discontinued the lesions bear a strong resemblance to those of human atheroma.—The Exotoxins of the Hæmolytic Streptococci, by J. Smith (Aberdeen). A long series of careful experiments leads to the conclusion that all hæmolytic streptococci (mastoiditis, osteomyelitis, erysipelas, puerperal septicæmia, scarlet fever, &c.) produce identical exotoxins; all are neutralised by scarlatinal horse antitoxin or the serum from a convalescent case of scarlet fever.—The Stability and Solubility of Diphtheria Toxin in Acid and Alkali, by Una Wallace (Beckenham). Alkali is more destructive than acid.—Complement Fixation in Mixtures of Toxin and Antitoxin, by H. R. Dean (Cambridge). With some difficulty it is demonstrated that the flocculation reaction between diphtheria toxin and antitoxin is accompanied by fixation of complement.—The Monocytes of the Rabbit in *B. monocytogenes* Infection, by L. J. Witts and R. A. Webb (Cambridge). Monocytes may be recognised by their reactions to supravital staining; they come from the spleen and bone-marrow and cannot be identified with clasmatocytes.—Regeneration of the Pancreas, by G. R. Cameron (Melbourne). Partial removal of the pancreas in guinea-pigs is followed by regeneration of acinar and islet tissue which is inhibited by giving insulin or pituitrin. Pituitrin causes hypertrophy with a relative increase in islets.—Note on Preparing Mucicarmine, by H. W. Southgate (Croydon).—Obituary notice with portrait of C. Da Fano.—Book reviews. THE LANCET.

LONDON, SATURDAY, NOVEMBER 12, 1927.

MEDICINE AND THE CHURCH.

SIR FARQUHAR BUZZARD, in his recent address at ork published in this issue, describes the varying elations that have existed between medicine and the hurch through the centuries; the harmony of these elations has always been a direct concern of mankind, hich turns either to the physician or the priest in time f trouble. Progress in medicine has been synchronous ith a gradual separation from the Church, and now ie public places a reliance upon medicine which, s the speaker might have said without departing om his theme, sometimes leads the cynic to declare iat man has found a new object for the faith once evoted only to the Church. We are viewed as the ossessors of a gift of healing which neither medicine or the Church may rightly claim, but the psychologist, ren if he be one who subjects religion itself to psychogical analysis, recognises that many men need ipport, something upon which to lean, and this need sts upon no rational basis but demands satisfaction the face of all reason. "Faith," says Sir FARQUHAR UZZARD, "even if it is defined as the ability to believe iat which there is no reason to think is true, is one the commonest attributes of the human mind and, gether with the almost universal fear of pain and ckness, forms an ideal and abundant soil for the work the spiritual healer." Are we justified in leaving is soil untilled? Should we be permitted to do so ren if we desired? The public shows no sign of easuring our powers in the light of reason; its emands for enlightenment are not for knowledge it authoritative declaration upon which they may se a ritual of diet or drugs. When authority ffers within itself—as it must when called upon for nswers to questions that are unanswerable—the mand is for still higher authority that will provide sure support. So great are the powers attributed the magic of medical science that the public is grieved by the many diseases that remain unchecked; rely if the magic were only properly used the secrets their cause and cure would be revealed. The cynic as right; man must have an object for the faith at is within him and, whether we like it or not, edicine now serves him as the object. Sir FARQUHAR UZZARD'S exposition of the limits of our powers is ndid and welcome, and his disclaimer of the gifts healing follows logically upon his views; none the ss, we shall be credited with something unknown id unintelligible—something not due merely to the ility to solve scientific problems.

But, whilst he demands from medicine the renuncian of the claim to cure, Sir FARQUHAR BUZZARD asks less from the Church. Weight of religious authority against the claim to cure "organic" disease, and looks forward to the time when the Church will ve the courage to say that she makes no claim to iritual healing. He is to be commended for this rectness; he knew that there would be criticism, id only by the expression of varying views can we tain clearness. He takes the pathology of encephaitis lethargica as a type of disorder illustrating the lationship of mind and matter without indicating e narrow limits within which such relationship is nown to exist. The changes of character after encephalitis result from gross lesions of nerve structure followed by the liberation of instinctive urges which are normally under the control of higher centres now destroyed by disease. But do we know that disorders of structure always precede and determine disorders of emotion and behaviour? Are the racking doubts and fears of the psychasthenic, his stammerings and indecisions at times of stress, to be attributed to structural changes any more than are the criminal tendencies of other people, their gastronomic likes and dislikes, or their fierce political opinions. When Sir FARQUHAR BUZZARD writes that "the use of the adjective 'functional' indicates that the disease or disorder described is attributed to a disturbance in the function of an organ without a physical change of structure such as we are able to detect," he allows for the belief that some physical change exists which some day we may hope to detect. Discussion here would soon lead us away from physiology to metaphysics, and it may be asked fairly whether, in the present state of our knowledge, anything more than chance has decreed that the troubles of the psychasthenic, or even the hysteric, should belong to medicine rather than to the Church, or whether our use of the phrase "functional nervous disorder" serves any other purpose than to signify our belief that they do so belong?

That in undertaking spiritual healing the Church might see herself in competition, not with medicine, but with quacks and charlatans, is an admission that there are sufferers who, failing to get relief from the methods of orthodox medicine, find it either at the hands of charlatans or in the ministrations of the Church. We know, indeed, that this is sometimes true of psychasthenics; and so long as that is so we must expect them to seek help in those quarters. The reasonable hope is that as our knowledge progresses steadily the number and variety of cases unrelieved by scientific medicine will decrease steadily. The dangers of unqualified meddling in organic disease are beyond dispute. If in the undefined territory of functional nervous disorder, with its associated mental conflict and worry and maladjustments to the demands of life, the line of demarcation between the functions of medicine and those of the Church may not be capable of exact determination at the present, this is not to say that the boundary is in any sense final.

LARYNGECTOMY.

THE story of laryngectomy is the familiar one of a difficult operation designed to meet a desperate need. At first performed in unsuitable cases and attended by a high mortality, in the hands of a few under certain conditions it has become comparatively safe. Gradually the scope and limitations of the operation have been laid down, the contra-indications defined, the details of technique, preparation, and after-treatment elaborated, with the result that the mortality has been lessened and the percentage of cures increased. This is the position which Mr. LIONEL COLLEDGE reviewed in his Semon lecture on Nov. 3rd. He pointed out how laryngectomy had been applied to cases of extrinsic cancer of the larynx (really pharyngeal cancer) in which the growth had originated on the aryepiglottic folds or epiglottis, to post-cricoid carcinoma, and to growths arising in the fossa pyriformis. In the first class of these cases, lateral pharyngotomy, as planned by Mr. WILFRED TROTTER, is the more suitable operation; in the second class it is not always necessary to excise the larynx, for in suitable cases a pharyngotomy, combined with the

use of plastic skin-flaps, will allow the resection of the lower part of the pharynx and upper end of the œsophagus. For the third class, that of tumours of the pyriform fossa, the only prospect of success is given by the removal of the larynx with a portion of the pharynx; GLUCK was the first to demonstrate the possibility of carrying through these very extensive operations to a successful conclusion. Mr. COLLEDGE complained that statistics and case reports commonly make no sufficient distinction between cases of excision limited to the larynx and these cases in which it has been combined with partial excision of the pharynx; at the present time, he said, the operation should be judged by its success in dealing with cases of intrinsic cancer too advanced for such a conservative measure as laryngo-fissure—where, for instance, the disease has extended widely in the subglottic region, or has crossed the anterior commissure and invaded both vocal cords, where one or both cords are fixed and there is extension to the arytenoid region, or where the cancer has recurred after laryngo-fissure.

To estimate the relative success of laryngo-fissure and laryngectomy may be difficult or impossible, for the selection of cases varies greatly with different surgeons and in different countries. Thus TAPIA, of Madrid, has reported 107 cases with five deaths due to the operation, and it is possible that many of his patients would have been considered suitable cases for operation by laryngo-fissure in this country. In New York J. E. MACKENTY has performed 102 total laryngectomies as against only 22 thyrotomies; he writes "on some amazing statistics of cures by thyrotomy, and even by excision under suspension. Is it possible that the general profession in the regions from which these statistics emanate is more enlightened and more alert in the detection of laryngeal cancer than we are in New York and its environs?" Mr. COLLEDGE answered this question in the affirmative; he considered it evident that a large proportion of Dr. MACKENTY'S patients were not seen by him until they had reached an advanced stage, since he had only obtained 66 per cent. of cures after laryngectomy for intrinic cancer, against some 80 per cent. of cures after thyro-fissure reported in British practice. But here, too, there is room for improvement in the early recognition of cancer of the larynx. Some patients may not seek prompt advice for the vocal impairment which is usually the only early symptom, but the laryngologist still sees far too many cases which have been treated for hoarseness without adequate examination until the cancer has spread too far for removal by thyrotomy. The lesser operation of laryngo-fissure, of course, gives a far better functional result than laryngectomy—a further reason for urging that patients be sent for treatment at an early stage. In illustration of this point, Sir STCLAIR THOMSON showed at the meeting of the Laryngological Section of the Royal Society of Medicine (reported on another page) four medical men on whom he had performed the lesser operation at periods varying from 2¼ to 5½ years previously. All had useful voices and were engaged in practice.

The Semon lecturer concluded by discussing fully the ultimate results of laryngectomy from the point of view of function. He found that most patients develop a useful pharyngeal whisper, occasionally quite a loud voice, that they are usually cheerful and active, and that there is no direct evidence of special liability to pulmonary disorders. As the result of the abolition of nasal respiration, they are indeed remarkably free from coryza. The permanent tracheotomy is part of the price paid for the cure of a disease which, unchecked, would eventually necessitate this operation in almost every case. It may be claimed, therefore, that the patient's ultimate condition is no worse than that of one suffering from any form of permanent or complete laryngeal stenosis.

DIET AND THE TEETH.

THE introduction to the last report of the Medical Research Council says that there is evidence suggesting that the structure of the teeth is a sensitive index of the national health. This statement doubtless refers to Mrs. MELLANBY'S work on the relation of diet to calcification, for the direction of her research during the last ten years has been to show that normal dental development depends on a sufficiency of the fat-soluble vitamins A and D in the diet. Her earlier results showed conclusively that in puppies the teeth can be modified according to the diet employed, and in 1923 she recorded an attempt to apply these findings to human pathology. Examination of a number of deciduous teeth showed that a large proportion were defective in structure and might be regarded as hypoplastic, and it was found that these hypoplastic teeth were abnormally subject to caries. At that time the number studied was small, but a more recent paper [1] describes observations of over 1000 deciduous teeth. They were first examined with the naked eye to detect any roughness or pitting which might indicate defective structure, and were accordingly graded as normal, slightly hypoplastic, hypoplastic, or severely hypoplastic. Ground sections were then made and the conditions of the enamel and dentine were noted, the latter being mainly relied on to provide a general index of the degree of calcification. The chief indication of defective structure was considered to be the presence of interglobular spaces. Dentine is built up of calcospherites which fuse together to form a matrix penetrated by the dentinal tubes, and the presence of interglobular spaces shows that these calcospherites have coalesced imperfectly, which makes the dentine softer, less homogeneous, and presumably more readily attacked by caries.

Mrs. MELLANBY'S scrupulous examination of the deciduous teeth showed that 14 per cent. were normal, 21 per cent. were slightly hypoplastic, and 64 per cent. were severely hypoplastic. The deciduous incisors were better calcified than the deciduous molars, 49 per cent. of the incisors being normal as compared with 1 per cent. of the second molars. The explanation of this disparity is said to be that the crowns of the incisors are mostly calcified in utero, when the fœtus is really carnivorous and is shielded from any deficiency in the maternal diet. The greater part of the deciduous molars is formed after birth, especially during the first few months of life when the infant is highly susceptible to dietetic deficiencies. It was interesting to find that only 9 per cent. of the teeth obtained from school clinics were normal as compared with 28 per cent. of those which came from the private practice of dentists. Nearly 300 permanent teeth, chiefly first permanent molars, were examined in addition, and none of them could be classed as normal. But as Mrs. MELLANBY fairly points out, they had all been extracted for some reason or another, and therefore were not a normal sample of the condition of the permanent teeth.

Three questions arise from this laborious and valuable investigation. First, what is the normal structure of deciduous teeth? An examination of Mrs. MELLANBY'S microphotographs leaves no doubt that

[1] Brit. Dent. Jour., July, 1927.

the cases of severe hypoplasia the structure is fective to an extent which diminishes the density the teeth; but it is by no means easy to be sure hat is the significance of interglobular spaces as an dex of faulty calcification. There are few sections teeth which do not reveal some trace of these aces, and it is arguable that without serial sections is impossible to say that they are absent in any rticular tooth. Interglobular spaces are very merous in the teeth of whales, and also of horses; t in these animals no one would regard them as a fect of structure, and still less as evidence of etary indiscretion. Mrs. MELLANBY'S thesis pears to be that what may be termed lapses from e ideal architecture of the tooth—a degradation of ucture—are associated with deficiency of fat-luble vitamins. This is a reasonable hypothesis, t before it is accepted, it would be convenient to ow the average structure of the deciduous teeth the people of this country in the days when diet s more natural and the amount of caries—for one ason or another—was less. It would be useful also have similar data concerning the teeth of other es both past and present. The second question is, w far is defective dental structure due to deficiencies diet? Is it certain that a balanced diet will ensure e growth of well-calcified teeth? Comparative dy of the microscopical structure of a large number specimens should do much to decide these problems, ough it is difficult to apply the results of animal periments to the human organism. The last estion is perhaps the most important. Does s. MELLANBY'S work provide a sufficient explana-n of the increased prevalence of dental caries, and it justifiable to hope that more rational dietetics ll produce teeth which will offer a greater resistance decay? At the present time our answers have to guarded. There is little doubt that deficient ucture is of vast importance in predisposing to ies, but it would be hazardous to assume that re has been a progressive degradation of the ucture of the teeth or that such a degradation is chief factor in the present high incidence of dental ease. Even if we could be sure that the architecture the teeth has deteriorated we should still have to member that there has also been an alteration in dietetic habits of the nation, involving a steady rease in the consumption of fermentable carbo-drates and a decrease of the fibrous elements ich scour the teeth and help to keep them clean.

ROYAL MEDICAL BENEVOLENT FUND GUILD: AN APPEAL.

ONLY once before has this Fund made a public peal—namely, in 1923—when the movement was ugurated for founding in memoriam scholarships. w, in order to raise £3000 in aid of the educational rk of the Guild, Lady Fripp is organising a ball be held at the Mayfair Hotel, on Thursday, c. 1st, at 10 P.M. The Duchess of York, the first yal Patron of the Guild, has intimated her intention being present. Tickets, if sold before Nov. 23rd, l be 2 guineas each, including certain refreshments. is unnecessary to call the attention of our readers the good work done by this Guild, and by the yal Medical Benevolent Fund, of which it is an shoot. The public, however, do not realise that re is any distress among members of the medical fession, and no opportunity should be lost by se in a position to point out the merits of such excellent institution as the Guild. The ball, to organisation of which Miss Tweedy, 100, Harley-eet, W., is acting as honorary secretary, will afford admirable opportunity to help practically where p is sorely needed.

Annotations.

"Ne quid nimis."

VENOUS PRESSURE.

ON all sides there is a tendency to replace the older empirical methods of clinical observation by accurate measurements and estimations, and though these are often too elaborate and expensive for use in general practice, many are of value in the investigation of disease and in judging the effects of treatment. An instance of this tendency is the estimation of venous pressure which has been used to some extent in America as a guide to prognosis and treatment in cases of heart failure. The method, perfected by Hooker,[1] consists in sealing a small glass funnel connected with a rubber bulb and a water manometer over a vein on the dorsum of the hand. The pressure is raised by compressing the bulb and the reading of the manometer is noted at the point at which the vein collapses. A correction is then made according to the position of the hand above or below the level of the right auricle. It is possible to get very accurate results by this method, and it has been established that the average venous pressure in a normal person never rises above 11 cm. of water. In cases of heart failure the pressure is more or less raised, usually to between two and three times the normal figure. A healthy ventricle with good reserve of power contracts with a force proportional to the amount of diastolic filling. A heart with little or no reserve is unable to respond to the load of venous pressure and contracts with decreasing vigour the more this is raised. Consequently the pressure in the veins rises still higher and the clinical picture of congestive heart failure becomes well established. Measurement of the venous pressure, therefore, registers with some precision the degree to which cardiac reserve is impaired. Clark [2] has shown that a fall or rise of venous pressure may give an indication of impending improvement or relapse one or two days before the change is apparent clinically by such methods as a comparison between fluid intake and output. Recently Eyster and Middleton [3] have investigated by this means cases of heart failure in which venesection was indicated on ordinary clinical grounds—that is to say, cases that showed cyanosis, dyspnœa, and congestion of the lungs. They found that in all such cases the venous pressure was raised before venesection and that an initial fall followed the operation. If the fall was maintained during the next 48 hours the prognosis was good, as it showed that the heart had some reserve power once it was relieved of the excessive load of venous pressure. If, on the other hand, the pressure soon rose again to an abnormal level, it showed that there was not strength in the myocardium to cope with even a moderate venous return and the prognosis was correspondingly bad. The apparatus is simple and the technique should prove easy to acquire. The results are far more accurate than those obtained by the better known Gaertner's test, and the method seems worthy of further investigation on this side of the Atlantic.

"REMINISCENCES OF A NAVAL SURGEON."

To Surgeon Rear-Admiral Jeans, C.M.G., all hours afloat are sunny or that, at all events, is the impression gained by reading his attractive account[4] of service in the Navy. So well and so gratefully does he remember his first seagoing ship that it is a picture of her "lovable" captain, the well-known Sir Edward Chichester, that Admiral Jeans presents as frontispiece. This captain was one of the dogged, good-

natured West Countrymen of whom so many have adorned the records of the Navy, so unselfishly proud of *Immortalité* that she was to him, and to the ship's company, "our" ship, never "my" ship, as many senior officers phrase it. All the writer's ships were "happy," yet like every seaman he enjoyed going ashore in South Africa to do a bit of soldiering with the 4·7 naval guns. There were compensations too, for "the Army," he says, "always treated us as their guests throughout the war." Admiral Jeans gives an intimate account of Lord Roberts and Lord Kitchener directing the battle of Poplar Grove from the naval gun position. He was also in the Great War where he found Gallipoli, with its squandered lives and gallantry, a veritable nightmare. Midshipmen at Gallipoli did their work well, but were too young to stand the continual strain; sleeping badly on their days off was the first sign of breakdown. The author is brave enough to doubt whether the present scheme for training cadets to be naval officers from the age of 13 years gives the country the best possible class of officer. Admiral Jeans is a skilled story-teller, his books about the Navy for boys are well known, and he has here many a good yarn to spin and some pictures to show. He was fortunate in being taught while at Haslar—by the son of a D.G., A.M.D.—to sail a boat; and when he gave up football at the age of 46 he discovered the joys of "medicine ball." He had little opportunity, on the other hand, for surgery till he had served for 15 years, and another 15 years later he reached the retiring age. Unwillingly enough, for his last sentence runs: "If I had my life to live once again I should retread my steps." This is a book which will make many young practitioners take thought about joining the Naval Medical Service.

FOOT-AND-MOUTH DISEASE AND EPIDEMIOLOGICAL THEORY.

IN the current issue of the *Journal of Hygiene* (1927, xxvi., 465) Prof. Major Greenwood sets out to portray and explain the most important features of an epidemic of foot-and-mouth disease. The difficulties of such a task are acknowledged. Among them are the inaccuracy of records—due to causes which are common to many diseases of man and animals, such as concealment or delay in notification of fresh cases—and the difficulty of tracing human and animal movements, and of ascertaining the sources of food-supply, and of other possible inanimate fomites. A further obstacle to epidemiological inquiry is the poverty of data bearing on the age and susceptibility of the animal population before and during an epidemic.

Prof. Greenwood takes the available data on foot-and-mouth disease in Holland and endeavours to explain them in the light of recent experimental research. Though the artificial epidemics studied by Topley and Greenwood [1] in this country and by Webster in the United States were amongst mice and were due to bacterial diseases—pasteurella and *Bacillus œrtrycke* infections—the fundamental principles may well apply to infective diseases very diverse in their causes and in the hosts affected. The two main assumptions needed for the particular hypothesis of epidemics stated by Topley and Greenwood are: (1) The persistence of sources of infection between epidemics, probably in recovered animals which act as carriers. In these the infective microbe is believed to be in a form which is non-virulent or at any rate will not readily spread the disease. (2) The addition to the community of new susceptible individuals which is held not only to be necessary for the production of an epidemic, but also by the number and the rate of their introduction to modify its course profoundly. The "circulation of non-immunes" is reasonably supposed to act by altering the infective agent in the course of its passage through susceptibles during the early and pre-epidemic periods. All this is very suggestive and stimulating for human and animal epidemiology. The difficulty in applying th results to foot-and-mouth disease is, first, that th epidemiological facts are insufficiently recorded t make sure that they fit the hypothesis; and, secondl that the postulates regarding ever-present foci infection and variation in the supply of susceptible whether by birth or import, lack adequate suppo from the records. That these lacunæ will be fille in the case of future epidemics is much to be hope Carriers of foot-and-mouth disease in cattle a stated to have been found occasionally, but so f with great rarity. On the other hand, much has bee recently learnt about the possibility of introduci infective material from an outside area on dea carcasses, dried fodder, and the like. The discoveri in this direction are recorded in the progress repor of the Foot and Mouth Research Committee.[2] T information about variation in the numbers ar distribution of susceptibles in the cattle populati is very defective, and Prof. Greenwood makes t suggestion that a detailed record of the number, ag and sources of all farm animals in a limited area areas over a long period might be possible a would be valuable.

Concerning practical measures Prof. Greenwood naturally restrained, in view of the incompletene of his data; but he does state the conditions whi appear to him to be suitable for an attempt at stampi out the disease by slaughter. Where, as in Hollar the land frontiers are long and intercourse across t border is free or difficult to control, and where, mo over, the disease is never absent for long and numero foci of infection are probably always present, considers that a policy of slaughter is not hopef Such a policy has its best chance, he points out, a is a reasonable procedure in an isolated count where import of new animals does not occur or s well controlled, and where the disease completely d out and foci of infection are absent between epidemi As to whether Great Britain is an example of the lat case he evidently has some doubts, since the sou of fresh outbreaks is often very obscure and impor tion from abroad usually unproven; but he does n dispute the justification of the present slaugh policy. Efforts to trace the origin of new outbrea may well be more successful in the future than hithe as the result of the recent additions to our knowled of the survival of the virus outside the animal bod The work in this direction is, however, of recent da and its applicability to the infection of farm anim has not been adequately tested.

ELEMENTARY MEDICO-LEGAL PRINCIPLES.

THE examination of patients having medico-le injuries and the lucid presentation of their case a report or in the witness-box is often most difficu calling as it does for a thorough knowledge f anatomy and some acquaintance with varie branches of physics. The lay person cannot expected to arrive at a definite diagnosis or assess the appropriate amount of damage, even apparently simple conditions. Mr. A. McKendric important book, which we review on another pa does not attempt to teach the layman medicine, it does aim at showing him how the medical m conducts the necessary examinations, making clear far as possible the processes of reasoning which cond to diagnosis. One of the most difficult problems t the medical assessor has to face is the determinat of the amount of incapacity occasioned by a s joint. Here the author's advice is to write in report not only the number of degrees throu which a particular joint can be moved, but also w the patient can do—e.g., with a stiff elbow he c or cannot, get his hand in his trouser pocket, a fork to his mouth, or brush his hair. Incapacy expressed in this way becomes intelligible to non-scientific. The main principles involved in treatment of fractures are clearly stated in a spe

[1] THE LANCET, 1926, i., 477, 531, and 645.

[2] See THE LANCET, 1927, i., 499.

apter devoted to the subject, and great emphasis laid on the necessity of early movement in all cases, e following sentence being in italics: "The one ject in all cases of fracture of a long bone should be make an attempt to restore functional utility of e limb as quickly and as fully as possible." This the avowed aim of every surgeon who treats a acture, and Mr. McKendrick is not alone in his inion that it can only be achieved by early move- ent of joints and muscles in the neighbourhood of e fractured bone. Two illustrations given of actured metacarpals are useful; in one a perfect atomical result was obtained, but the hand had en kept in an extension frame for six weeks, and the nctional result, owing to stiff fingers, was very bad; e other is an X ray of an ununited fracture of a cond metacarpal in a man who went back to work e weeks after a severe saw cut, and had no disability. ese and other similar cases prove that a good nctional result is better than a good anatomical ult as shown by X ray examination, but where lure to obtain union has occurred the matter is open serious discussion as to whether the very best ult, albeit a good functional result, was obtained such drastic early movement. Mr. McKendrick kes out a case for the organisation of special ntres for the after-treatment of workmen's injuries. the general hospitals it is nearly always impossible obtain the necessary massage and re-education less the patient is to obtain time off from work, ich he often cannot. Many a workman would able to do light work, sometimes full work, if he re not compelled to attend hospital several days eek during working hours; as a result and against will he remains idle. The yearly cost to the country greater than would be incurred to equip and run ntres where treatment could be obtained after rking hours.

ANCER AND TUBERCULOSIS: THEIR TOLL ON THE COMMUNITY.

N his 1926 report for East Suffolk Dr. B. Wood-White eavours to estimate the comparative economic loss sed by cancer and tuberculosis. He sets out to i a life value for the average individual as he passes ough each of the ordinary statistical periods, ring in mind that early marriage, and consequently ly freedom from the responsibility of starting the t generation, is the rule for the majority. To dren in the first year of life he assigns the arbitrary ue 5, a maximal value of 25 being reached at the -period 25 to 45, after which the figures descend 15, 3, and 0 for the next three periods. The owing table shows how the calculation worked out East Suffolk during the year.

ge-ups.	Fig. of value.	Cancer.		Tuberculosis.	
		No. of deaths.	Damage.	No. of deaths.	Damage.
- 1	5	0	0	2	10
- 2	6	1	6	1	6
- 5	8	1	8	4	32
- 15	11	2	22	8	88
- 25	18	0	0	33	594
- 45	25	24	600	58	1450
- 65	15	108	1620	31	465
- 75	3	121	363	6	18
-100	0	63	0	1	0
—	—	320	2619	144	2663

D Wood-White would like to have split up the 4[5] age-period, but the necessary figures were not available. On the other hand, if he had grouped the fi three periods and given the value of 7 to infants ar "toddlers," the result would have been substan- ti y the same, and the age-periods would have co esponded fairly accurately with the seven ages of Sh kespeare's melancholy philosopher. The life values se n to have been judiciously chosen, despite the fact th in these days of greater longevity the shrunken sh nks of the superannuated carry them through two rounds of golf in the day, and hearty octogenarians would wince at being regarded as sans economic value. In East Suffolk in 1926 the cancer death-rate was unusually high—namely, 1·54—while the tuberculosis rate was unusually low, 0·69; yet, according to the calculation, the damage done by the two diseases was identical. In any previous year the effect of tubercle would have been much more disastrous. East Suffolk is, of course, an agricultural district, and in some industrial areas the deaths from pulmonary tuberculosis occur late in life—e.g., Sheffield, with its grinders. In such places the damage done by tubercle as compared with cancer would be comparatively less.

"OUR LORDS THE SICK."

THERE is a popular impression, to which utterance is sometimes given in Hospital Sunday sermons, that hospitals are a characteristic product of Christianity and of the sympathy and pity which it engendered. How seriously this impression ignores history we are reminded by the learned and fascinating Thomas Vicary lecture on the Early Development of Hospitals, delivered by Dr. George Parker at the Royal College of Surgeons of England last week. Only those who have had laid upon them the duty, or have voluntarily undertaken the pleasure, of discoursing upon a more or less technical topic before a specialist audience can realise the pains that go to the presentation of a bird's-eye view of a great subject such as this. Dr. Parker's lecture was historical rather than technical and forms a valuable conspectus of the history, from long before the Christian era down to our own Middle Ages, giving a rather elastic meaning to the term, of hospitals for the sick, their growth in number and development. There have been periods of enthusiasm and periods of comparative indifference, but we have now reached an era which is not the less enthusiastic for being ordered by system and tempered by science. Dr. Parker shows that perhaps the earliest hospitals were those which, from about 500 B.C., accompanied the foundation of monasteries for the exercise of that religion of Buddha to which one-third of mankind still adheres. Not much later the Grecian Temples of Æsculapius seem to have begun to treat patients medicinally, and even earlier Greece had "a highly trained and well-paid public medical service" as well as many general practitioners, who, it is to be hoped, were equally well remunerated by grateful patients. Nor was Rome slow in establishing *valetudinaria* for rich, poor, and slaves, and the facility with which history repeats itself is suggested by the remark of Aulus Celsus that the medical officers of large hospitals had so many patients that it was difficult to give them individual care.

The social, political, and military troubles which eventually led to the collapse of the Roman Empire were highly inimical to the preservation of hospitals, and at one time Constantine actually ordered the public hospitals to be closed, though Dr. Parker makes the plausible conjecture that the order was really directed against Pagan shrines. When, after the inevitable period of struggle, Christianity came to its own, what may be called the modern development of institutions for the cure of disease began. They were established in most parts of Europe and were undoubtedly very numerous, though we may not be quite ready to accept the arithmetic of Louis VIII., who said that, at the end of the first quarter of the thirteenth century, there were in France 2000 hospitals. France was a much smaller country then than now, and that our ancestors were given to exaggerating figures we know from their fantastic estimates of the size of armies and the numbers of the slain in great battles—nobody can possibly believe, for instance, that 130,000 men fought at Bannockburn, or that 166,000 were drawn up in battle array at Crecy. It is the Church that we have to thank for the rapid increase in hospitals during many centuries. At quite an early date every bishop had his own hospice for the sick, and many of the cathedrals had them also—the famous, and still existing, Hôtel Dieu in Paris was dependent upon the Chapter of

Nôtre Dame. Nor was the individual founder, who was by no means invariably a monarch, lacking, as London knows full well. A "war-stricken and dismembered Christian world," to use Dr. Parker's phrase, looked upon it, as Rahere did, as a Christian duty to found infirmaries.

To Islamism as well as to Christianity these works of mercy were a duty, and the empire of the early Caliphs had many examples from which to draw inspiration. As early as 707 the Caliphate set up a hospital for the sick at Damascus, and in the same century Haroun al Raschid ordained that every new mosque at Bagdad should be accompanied by a hospital. The noble Bimariston hospital, established in Cairo in 1284 with an income equivalent to £25,000 a year of our money, still exists in part as a thoroughly modern ophthalmic hospital. When leprosy was rife during two or three centuries religious fervour was lending to the Crusades, and the Gilds were growing powerful, "hospitals soon became the passion of the age" and Orders of Hospitallers arose—the Teutonic Knights, the Knights Templars, the Knights of St. John of Jerusalem, the Lazarists, who especially tended lepers, the Order of St. Antony, and the Order of the Holy Spirit, the most active of them all, whose patients were called "Our lords the sick." By the year 1300 this Order had created 900 hospitals, one of which is counted among the ancestors of our own St. Thomas's. In these ancient "hospital movements" England did its fair share and 400 new ones appeared between 1100 and 1300, and here, as elsewhere, as lay management grew more efficient, ecclesiastical patronage was gradually withdrawn. The revolutions, great and small, sudden and gradual, which make up the sum of history, have extinguished vast numbers of ancient and mediæval hospitals, but it by no means follows that the world has lost by mere reduction of numbers, though for the matter of that there are certainly a larger number of hospitals, properly so called, in this realm to-day than at any former period. Increase of population and growth of specialisation must necessarily add to them, though it is obvious that specialisation has its perils. The hospitals of the Middle Ages owed as much in proportion to private benevolence as their descendants and representatives of to-day, and Dr. Parker has done well to remind us of the illustrious pedigree of institutions which never did better work than now, or did it amid more serious difficulties. Throughout a large part of their history they have owed more to voluntary effort, in money or in service, than to the patronage of Church or State. Founded upon human devotion, in one form or another, they are now more than ever dependent upon it, and it is well for humanity that it should be so. The State may foster and protect, but the real duty lies at the door of every man of good will.

AN EPIDEMIC OF ERYTHEMA NODOSUM.

A FEW weeks ago [1] we reviewed some of the evidence indicating that erythema nodosum is a manifestation of tuberculosis. Our article was written by way of comment on an outbreak of erythema nodosum reported by Dr. Maurice Mitman in the same issue of THE LANCET. It is interesting to read an account from Sweden [2] of similar observations in a girls' school during the early part of 1926. The author, Dr. Arvid Wallgren, of Goteborg, defined the disease in 1924 [3] as the exanthem of tuberculosis, and stated that it appeared at the end of the incubation period at the onset of tuberculin sensitiveness. He regards it as an individual rather than a general reaction in persons with a particular diathesis. The remarkable account which he gives of the epidemic supports this view. A girl of 11, with a history of scrofuloderma at 1½ years but of no other ailment, began in November, 1925, to cough and lose appetite and weight but was not incapacitated from attending regularly at school. In the middle of January she joined a class consisting of 34 girls aged from 10 to 11 yea She then had an obstinate cough and was feeli poorly. About eight weeks after her arrival the oth children, who had previously been in good healt sickened one after the other until 18 were confin to bed, 12 with fever and erythema nodosum and with bouts of fever that lasted for periods varyi from one and a half to seven weeks, and resist diagnosis by the ordinary methods. The newcon was isolated in May, and found to have advanc pulmonary tuberculosis with massive infection of t sputum and a positive Pirquet reaction. The oth were carefully examined, and except for three w had signs of earlier infection, and may be presum to have been immunised, the entire class was fou infected. Under X rays 13 had what were descri as obvious hilum shadows, 4 had suspicious hil shadows, whilst 14 had no detectable chang Six of the 13 had erythema nodosum and 6 had fe with no local symptoms; the remaining one g no outward signs of illness. Of the four suspe one had erythema and three were apparently w Four of the erythema cases had no suspicious h shadows. None of the class lived in tubercul surroundings.

THE ARMS OF THE ROYAL SOCIETY OF MEDICINE.

THE Royal Society of Medicine's new coat-of-ar which we illustrate below, is the gift of Sir StC Thomson. During his presidency it was decided t the Society ought to bear arms, as is the custom other Royal Societies, and a committee was for to discuss the form they should take. After l deliberation a design suggested by Mr. Martin Tra was submitted to the College of Heralds, by whor was accepted without criticism. Formal applicat was then made in Sir StClair Thomson's name, and patent has now been granted. In heraldic langu the coat is described as follows:—

Arms.—Per pale vert and gules, the serpent of Moses or, entwined round a tau cross argent.

Crest.—Three sprigs of the herb "all-heal" proper.

Supporters.—On the dexter side a representation of St. Cosmas and on the sinister side a representation of St. Damian both proper.

Motto.—"Non est vivere sed valere vita."

Thus the serpent is not (as might be supposed) the well-known representative of Æsculapius, but the raised by Moses to heal the people in the wilder The shield, on which the serpent is imposed divided vertically, half being red to symbolise Surg and the other half green to symbolise Medicine. the red side stands the surgeon carrying a knife, on the green side stands a physician holding Italian drug jar. These two figures are SS. Cos and Damian who suffered martyrdom in Italy in early days of Christianity, and, possibly owing to manner of their deaths, have long been regarde Catholic countries as the patron saints of medi and surgery. They were the patrons of the anc Guild of Barber Surgeons, and are shown in silve the beautiful instrument-case which used to carried in the processions of the Guilds in the Mi Ages. The representation of them which appea the new coat-of-arms is taken from a stained-g window in the Pazzi Chapel in Florence. The is three sprigs of the herb all-heal or wound-w which are seen above the helm. This plant was u used in the Middle Ages for binding up wounds for making up medicines. The new presidential b

ill consist of the shield done in enamel and gold, id will be handed over by Sir StClair Thomson at ie Society's annual dinner on Nov. 16th. It will e worn on a wrought gold chain of Florentine orkmanship, which he has already presented for the resident's use.

THE CHEMISTRY OF MONSOL.

THE clinical and pathological data upon which is ised the claim of the Mond Staffordshire Refining o. to have found a safe and efficient germicide have cently been placed before the medical profession. he basis of monsol is an oil obtained in the manufac- ire of power gas by the Mond process. It is in no sense secret remedy, and Mr. H. T. Pinnock, chief chemist the company, has communicated to us what is iown of its composition. The oil is free from benzole, luol, naphthas, and the solid hydrocarbons present the oils derived from the manufacture of illuminating s. Further, the alkali-soluble substances which onsol contains are free from the carbolic and cresylic id which occur largely in ordinary tar oils. Other rdroxy-bodies which take their place are present to e extent of more than 30 per cent. Careful study is shown that they consist of aromatic carbocyclic mpounds possessing side chains of high molecular eight, and it is to the presence of these bodies (which e not of the true phenol group) that monsol owes its ecial properties. Finally, in order to increase its itivity and powers of penetration, monsol is epared in a colloidal state.

THE Huxley lecture on Recent Advances in ience in Relation to Medicine and Surgery will be livered by Sir Archibald Garrod, F.R.S., on ursday, Nov. 24th, at 3 P.M., in the Out-patients' all of the Charing Cross Hospital.

THE next session of the General Medical Council ll begin at 2 P.M. on Tuesday, Nov. 22nd, when r Donald MacAlister, the President, will take the air and given an address. The Council will continue sit from day to day until the termination of their siness. The *London Gazette* announces that the ing has nominated Sir Leslie Mackenzie to be for e years a member of the Council.

IT is announced that the Karalinska Institute at ockholm has awarded the Nobel Prize for Physiology d Medicine for 1926 to Prof. Johannes Fibiger, of penhagen, and the prize for 1927 to Prof. Julius agner-Jauregg, of Vienna. Prof. Fibiger has won world-wide reputation for research on the ætiology cancer, and Prof. Wagner-Jauregg introduced the eatment of general paralysis of the insane by alarial infection.

THE King has approved the award of one of the yal Society's Royal Medals to Sir Thomas Lewis r his research on the vascular system. The President d Council of the Society have awarded the Copley edal to Sir Charles Sherrington for his work on urology, and the Buchanan Medal to Dr. Major eenwood for his statistical research and other work relation to public health. Information about the ction of officers and council will be found in our news lumns.

STEPS have been taken within the last few months bring the University of London into line with some the older universities by the formation of a Society Medical Graduates. An inaugural dinner for the rmation of the society, and the appointment of an ganising committee, will be held at the Langham otel, Portland-place, W., on Friday, Nov. 25th, at 30 P.M. Sir StClair Thomson will preside. All edical graduates of the university are eligible for embership, and those who wish to attend the dinner e asked to write to the acting honorary secretaries, r. Dorothy C. Hare and Dr. Charles Franklin, at 4, Harley-street, W. 1, before Nov. 21st.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXLIX.—THE TREATMENT OF POST-PARTUM HÆMORRHAGE.

I.* PLACENTAL.

SERIOUS hæmorrhage after the birth of the child may occur from the placental site as the result of failure of the natural mechanism of control. Traumatic bleeding from laceration of some part of the birth canal, usually the cervix or vestibule, is distinguished clinically by palpation of the abdomen when the body of the uterus will be felt hard and firmly retracted. In this article only bleeding from the placental site will be discussed, bleeding from lacerations being reserved for later consideration.

Control of bleeding is normally effected by the retraction of the walls of the uterus as it shrinks down and empties. The contractions of the third stage compress the uterine cavity and expel the after-birth; retraction compresses the uterine wall and the vessels passing through it and maintains control in the absence of active contractions. The mechanism can be seen at work most clearly during the classical Cæsarean section operation. There is often profuse bleeding from the uterine incision before the membranes are ruptured and the fœtus removed. After the escape of the waters and removal of the fœtus, the uterus shrinks down to half its previous size and its walls are more than doubled in thickness, and thereby the bleeding from the incision becomes greatly checked. After removal of the after-birth and the establishment of firm retraction there is no bleeding of moment from the placental site.

Causes of Failure to Control Hæmorrhage.

The causes of interference with the normal mechanism are much the same as those of failure of the uterine powers in the earlier stages of labour, and may be classified as follows:—

(1) General maternal states of which the most important are shock and grave anæmia (as from ante-partum hæmorrhage), toxæmic conditions and nephritis, fatigue, exhaustion and emotional states, overdosage with anæsthetic and analgesic drugs.

(2) Uterine conditions, such as over-distension by twins or hydramnios, fibroids, and adhesions to surrounding structures; exhaustion of the uterine muscle from severe or protracted labour or uterine sepsis, and possibly inherent muscular weakness from chronic inflammatory changes in the myometrium.

(3) Incomplete emptying of the uterus interfering with retraction such as retained placenta or portions of it.

Preventive Treatment.

Consideration of these causes will indicate lines for prophylaxis. More cases will occur in the practice of the careless and impatient; a thorough antenatal supervision and a proper conduct of the second and third stages of labour will reduce the incidence of bleeding almost to vanishing point.

In all conditions where there is an increased risk of post-partum hæmorrhage the attendant will be particularly on guard and have all preparations made. Antenatal treatment will be given in the toxæmias of pregnancy or other general disease, and precautions taken to avoid fatigue, serious exhaustion, and infection during labour. Rapid delivery when the uterine powers are exhausted and after serious hæmorrhage during labour—e.g., placenta prævia—is always dangerous. Hurry to effect delivery of the after-birth carries with it the risk of incomplete expulsion and its consequences. One special point may be mentioned. A full bladder—well recognised as inhibiting good uterine action in the second stage—may also interfere with the power to control bleeding in the third stage. Distension of the bladder should be watched for in

* Part II., Post-partum Hæmorrhage from Laceration, will appear next week.

the later part of labour, and the catheter passed on the first sign of the need for it. If labour is conducted with the patient on her left side she should be turned on her back during the third stage. The observation of the uterus through the abdominal wall, the manipulations for expression of the placenta, and for the control of bleeding, should it occur, are all more readily conducted in that position.

Signs and Symptoms.

There may be free and rapid loss per vaginam or blood may collect in the flabby and distended uterus and be largely concealed; hence the importance of constant or frequent observation of the state of the uterus by abdominal palpation. Unless there is no skilled assistance at hand or the attendant's attention is distracted by having to restore an asphyxiated infant or other urgent duty, it is wise to concentrate attention on the uterus, since early warning may be obtained by its softening and enlargement. At this stage rubbing and kneading will rarely fail to restore the hardness of the uterus, but once the large, soft, distended state is established restoration becomes more difficult. Abdominal observation should, therefore, be made frequently in spite of other pre-occupations. A watch should also be kept on the patient's face for pallor, on the pulse, and on the general condition for the usual evidence of hæmorrhage.

Local Measures.

If bleeding occurs before the placenta is born and massage and kneading do not produce immediate hardening so that the fundus can be compressed in the palm of the hand, the after-birth must be delivered, for firm and permanent retraction will not be secured till the uterus is empty. Unless sufficient contraction can be obtained to allow the fundus and upper part of the body to be grasped between the fingers and thumb, it is inadvisable to attempt expression, since success is unlikely and inversion readily occurs when the placenta is expressed from a relaxed uterus. If conditions are favourable expression should be tried by squeezing the uterus like a sponge from above downwards; if this manœuvre is not immediately successful it should be abandoned. Violent and prolonged efforts may get rid of the placenta by tearing away the detached portion and leaving some part still attached. If expression fails or the uterus remains large and flabby, the after-birth must be removed manually. This operation is recognised as the one among all internal manipulations that carries with it the greatest risk of infection, both because the fingers work in immediate contact with the placental site and because of the lowered general condition of the patient at the time. Nevertheless, the emptying of the uterus should not be postponed till the serious condition of the woman demands desperate measures, but should be done as soon as the failure to secure control of bleeding by obtaining firm uterine retraction becomes obvious. The hand must be gloved and every precaution taken to minimise the chances of infection being carried up to the uterus. The outside hand plays a very important part—it presses down and supports the flabby bag during the separation of the placenta by the inside hand; before removing the hand and placenta, the opportunity is taken to stimulate the uterus to contract by massaging it firmly from the outside, if possible, till it is felt to be gripping the hand within, when, so to speak, hand and placenta may be expressed from above. Keeping up the hold on the uterus through the abdominal wall, a hot intra-uterine douche (118° to 120° F. in the douche-can) is next given, the nozzle being run up to the fundus so that it can be felt there by the external hand. The douche should be copious—at least half a gallon—and the heat is the important matter. An antiseptic (e.g., tinct. iodi ℥ i. or ℥ ii., ad O i.) may be added so long as it is not poisonous or rapidly absorbed. Should the emergency be such that the douche is not ready at once, bimanual compression of the uterus must be carried out during the period of waiting. The hand is inserted into the vagina, preferably into the anterior fornix, and doubled up with the knuckles against th anterior wall of the uterus and the fingers behin the symphysis, while the external hand behind th posterior wall crushes the uterus down on to the fi and symphysis.

Very rarely does the hot intra-uterine douche fa but should it not prove effective, bimanual compressio must be resumed, as firm pressing together of th uterine walls acts as a substitute for retractio As soon as the uterus is empty its activity shou be stimulated by an intramuscular injection pituitary extract or a preparation of ergot. As show by A. Bourne and J. H. Burn, the injection of 2 uni of pituitary extract is sufficient and may be repeate in an hour; the most effective way of giving erg is to inject 1 mg. (or 1/65 gr.) of its active princip ergotoxin or ergotamine.

Hæmorrhage after Expulsion of the Placenta.

In hæmorrhage after expulsion of the after-bir treatment should follow on the same lines. Th failure of retraction may then be due either exhaustion of the uterine muscle or to retentio of a portion of the placenta. Frequent observatio of the uterus by a hand on the abdomen will gi early warning of relaxation, when massage a kneading of the uterus, together with the injectio of pituitary extract or ergotamine, will almost alwa prevent the condition from becoming serious. the uterus is too large to be contained between t thumb and fingers, it should be compressed betwe the two hands, squeezed empty of clot, and a h intra-uterine douche given at once. Owing to t danger of infection, the passing of the hand into t uterine cavity should be reserved for those cases which examination of the after-birth shows undoubt evidence of the retention of some portion of p'acent missing portions of membrane alone do not justi the risk of uterine exploration. In the gravest cas with rapid and profuse hæmorrhage, the urge necessity of its immediate control is a justification passing the gloved hand into the uterus, while t other hand compresses the uterine walls from t outside on to the closed fist within till contracti on to the inside hand begins. Very rarely, howev will more be required than bimanual compressi on to the fist in the vagina, for though it is diffic to exert compression over the whole of the lar soft bag of a relaxed uterus, squeezing of the wa together will control the bleeding from the placen area.

The whole palm may be spread out over the posterior wl and fundus and the uterus squeezed down against symphysis and fist in the vagina. Fatigue, especially of external hand and arm, may be lessened by leaning weight on that hand and, when relief is needed, the nu or other assistant can press on the hand and even allow to be withdrawn for a rest, keeping up the pressure me time. The elbow supporting the inside hand obtains purchase by being wedged into the bed, and, acting passiv as the fixed object against which pressure is made, t arm does not tire so quickly. Some pressure on the ac may also be exercised during compression and may h to check bleeding. As uterine retraction returns, compress may be relaxed until it is possible to substitute a gradua compress under an abdominal binder. Plugging of uterus is a difficult and dangerous operation if perfor outside a hospital, since the necessary amount of ste material will rarely be immediately available, and n only be adopted if the recovery of retractile power in uterus is long delayed. Strips of turkish towelling or ot improvised material may be boiled and wrung out wh compression is maintained and the uterine cavity tigl filled in desperate cases.

Conclusion.

The above measures provide a consecutive plan campaign which will control bleeding even in the m serious cases provided the exhaustion of the pati has not reached a degree that renders recovery function in the uterine muscle unlikely. Treatm for shock and collapse from loss of blood should foll the checking of hæmorrhage.

JOHN S. FAIRBAIRN, B.M. Oxf., F.R.C.P. Lond. F.R.C.S. Eng.,
Obstetric Physician, St. Thomas's Hospital, London.

Special Articles.

HISTORY OF BRITISH MIDWIFERY.

THE FITZPATRICK LECTURES.

Dr. Herbert Spencer delivered the FitzPatrick ctures at the Royal College of Physicians of London n Nov. 8th and 10th, his subject being the History of ritish Midwifery from 1650 to 1800.

After introductory remarks on the midwifery rceps and the secrecy with regard to their invention nich the Chamberlens maintained for nearly a hundred ars, Dr. Spencer stated that this secrecy had a nsiderable influence in introducing the man-midwife to the practice of midwifery. His résumé of the es of the Chamberlens, from Aveling's work, showed e forceful character of the most prominent members the family, their multifarious schemes for the nefit of humanity and themselves, and the influence ey obtained, as a result of the possession of their cret, with king, lords, commons, and people. They ade efforts to obtain the incorporation of midwives der their own supervision and were frequently in nflict with the College of Physicians. Hugh amberl n the elder rendered a service to British prac- ioners by translating Mauriceau's "Observations" 1673; in the preface to the translation he nounced that his family had a secret method of livering women (the forceps), which, however, failed ien tried on one of Mauriceau's patients. Dr. Hugh amberlen the younger was a respected Fellow of e College. Dr. Peter Chamberlen, who had been cted a Fellow on the understanding that he adopted more sober dress, was frequently subjected to ciplinary measures by the College and was finally prived of his Fellowship on Nov. 23rd, 1649.

In 1650, said Dr. Spencer, Ent carried off e manuscript of Harvey's "De Generatione imalium" and published the work in 1651. It ntained the chapter "De partu," which was the st original work in midwifery to be published by British author. Of the chief writers and writings midwifery which followed, up till 1800, the lecturer ve biographical and bibliographical particulars. The iters, 25 in number, ranged from Harvey to Inman. Attention was directed to John Maubray as e first British teacher of midwifery, in 1725, to the portant action taken by the University of Edinburgh establishing, for the first time, a professorship of dwifery in 1726, and to the rapid improvement ich followed the general use of the forceps. After ing an account of the opposition of midwives and ctors to the new class of men-midwives, which had gely died down by the end of the eighteenth ntury, Dr. Spencer described the epidemics of erperal fever which followed the establishment of ng-in hospitals, and mentioned works on the bject from the time of Willis, who in 1660 gave it e name of *febris puerperarum*, to that of A. Gordon, o, in 1795, pointed out its infectious nature and its nnexion with erysipelas, and recommended disin- fion of the attendants. Nathaniel Hulme was of e opinion that puerperal fever was as much an iginal or primary disease as ague. Harvey laid the undation of our study of the fever by recognising e large internal wound produced by the separation the placenta as the starting point of the disease. he British obstetricians early rejected the theory of nk-metastasis and the view that the disease was identical with typhus and limited the causes to local fection of the uterine wound and general infection om foul air. Measures were devised for disinfecting the ng-in room by washing and fumigation, and the uterus by injections (Harvey) and drainage (Charles White).

In a brief review Dr. Spencer alluded to the work Harvey on embryology and to the illustrated work W. Hunter, Smellie, and Denman on the anatomy the pelvis, pregnant uterus, and fœtus; to the tings of Smellie, Burton, and W. Johnson on pelvimetry and cephalimetry; of Smellie and Fielding Ould on the mechanism of labour and of Smellie on deformed pelvis. With regard to the management of pregnancy and normal labour, John Maubray was the first British obstetrician to advise prematernity care; Charles White and Leake introduced hygiene into the lying-in room; John Harvie was the first to employ abdominal expression of the placenta, and Pugh and Smellie were pioneers in the prevention and treatment of asphyxia in the child. Version was usually podalic, and Pugh performed it bimanually. The forceps, invented by Peter Chamberlen, was first made public by Chapman in 1733. The invention of the pelvic curve which had been erroneously attributed to Smellie, was probably due to Levret, though possibly to Pugh. The fillet was soon abandoned owing to the injuries it inflicted on the child; but the lever was preferred by many men-midwives and the "living-lever" of Aitken was an ingenious instrument for the conversion of a face presentation into a vertex. The method of delivering the after-coming head, often attributed to Mauriceau and Smellie, was invented by Giffard. The milder degrees of contracted pelvis were treated by version, forceps, or lever, and the more severe forms by craniotomy, Cæsarean section and symphyseotomy being rarely performed on account of the danger attending them.

Induction of premature labour (1756) and Lucas's method of diminishing the size of the child by restricting the diet of the mother (1794), were practised in order to avoid craniotomy, which was performed with excessive frequency by Osborn. The hæmorrhages most frequently recorded were of the ante-partum variety. Placenta prævia was described by Giffard (1731) and was usually treated by podalic version. Post-partum hæmorrhage was treated usually by sedatives and tonics, sometimes by styptics; cold applications were also employed; there was no record of manual compression of the uterus to control hæmorrhage. Several cases of inversion and of rupture of the uterus were recorded, and McBride was the first to publi h a case of labial hæmatoma. Convulsions were treated by bleeding, blistering, opiates, hot baths, and clysters. Manningham recommended bleeding as a prophylactic. A few cases of ectopic gestation and of hydatidiform mole were published; of the latter the most interesting was Giffard's case, which died 12 months after delivery, apparently from chorion-epithelioma.

In conclusion, the lecturer said that during the 150 years since Harvey published his "De Generatione Animalium" a great advance had been made in the science and art of midwifery. This was due chiefly to the introduction of male practitioners, many of whom were men of learning and devoted to anatomy, the groundwork of obstetrics. The institution of lying-in hospitals by these male practitioners had an important influence in promoting teaching and research. The general introduction of the use of the forceps placed in their hands means of delivering women previously unknown, and by its results gradually overcame the opposition of the midwives, surgeons, and physicians to the new class of men-midwives. The action of the College of Physicians in instituting a special qualification of "Licentiate in Midwifery" was not without influence in improving the status of those practising midwifery, although the qualification ceased to be granted in the year 1800.

The characteristic of British midwifery at this period was conservatism. Although by some practitioners carried to excess, it led to laudable attempts, exclusively British, to avoid the operations of craniotomy which sacrificed the child, and Cæsarean section and symphyseotomy which so often proved fatal to the mother.

The forceps was sometimes used unnecessarily then, as now; but the abuse of operative methods of delivery is much greater at the present time, and no better corrective of that abuse could be prescribed than a study of the careful records of the British obstetricians of the seventeenth and eighteenth centuries, showing the resources of that "perfect operatrix," Nature, in effecting delivery.

MEDICINE AND THE LAW.

Unsuccessful Allegation of Negligence against Surgeon.

THE jury was not asked to express an opinion in the action of Beckh *v.* Sinclair in which the plaintiff claimed damages for personal injuries alleged to have been caused by the negligence of a surgeon who operated upon her, her knee having been burned by a hot-water bottle during the operation. After hearing the evidence on both sides the Lord Chief Justice stopped the action and said he was satisfied that there was no evidence to go to the jury. It was sought to make the surgeon responsible for the injuries in two ways. First and foremost it was said that the nurse was negligent and that the operating surgeon must answer for it under the doctrine of *respondeat superior*. According to the plaintiff's counsel there had been carelessness for which the surgeon was liable, because a surgeon was responsible for the negligence of a person assisting him at an operation and acting under his control. "If a surgeon delegates to a nurse the duty of placing and looking after the hot-water bottles at an operation he is responsible if she performs her duties carelessly and causes injury to the patient; a nurse is under the orders and control of the surgeon alone from the moment when the door of the operating-room is closed for the operation to begin." This contention seems to beg the question. It assumes that the surgeon delegates to the nurse the duty of looking after hot-water bottles; but such a duty must be the independent duty of the nurse; no surgeon is conscious of delegating it. Is the surgeon any more responsible for the hot-water bottles than he is for the temperature of the operating-table or for the proportions in which a lotion is mixed? Against this contention made by plaintiff's counsel may be set the professional evidence of two surgeons called as witnesses on behalf of the defence. A modern surgical operation, said Mr. Donald Armour, is a ritual at which, if it is to be successful, every detail must be carried out with meticulous care. Those who are present constitute a team, each member of which is trained in his own duties. As a rule a surgeon does not interfere to see whether the other members of the team have carried out their particular duties. The preparation of a patient is entrusted to the nurse, and this preparation includes the task of seeing that hot-water bottles are not in dangerous proximity. The modern nurse, Mr. Armour added, is a highly trained and skilled technician; "she is not a surgical tweenie." Mr. H. S. Souttar said that, unless there were a separation of functions at an operation it would be impossible to carry on modern surgery. It would be exceedingly dangerous if the surgeon allowed his attention to stray to any matter other than that on which he was engaged. After this evidence the Lord Chief Justice stated that he was satisfied that the surgeon, Mr. Sinclair, was not responsible for the negligence of the nurse—if indeed there were any negligence on her part, as to which issue he expressed no opinion. It was common ground, said Lord Hewart, that the nurse was to be paid by Miss Beckh, the patient, and was in no sense the servant or agent of Mr. Sinclair. As a second line of attack the plaintiff's case alleged, a little faintly, that Mr. Sinclair had himself been personally and directly negligent. He might, it was suggested, have exercised a superintending eye and satisfied himself that there was no hot-water bottle in a position likely to cause injury to the patient. This, said the Lord Chief Justice, was a far-fetched suggestion for which there was no support in the evidence. Judgment was therefore entered for the defendant on the claim and also on the counterclaim with costs. The counterclaim was for 15 guineas fees, which, of course, would not have been payable if the plaintiff had been able to prove the negligence which she alleged.

The case seems to have elicited a judicial confirmation of the rule that a surgeon has no personal responsibility for supervising the heating and placing of hot-water bottle. It must not, however, be relied upon in too general a way. All that it amounts to is that, in a particular set of facts, the court, after hearing the evidence, said there was no case to go to the jury. The court granted a temporary stay of execution, which presumably means that the plaintiff may seek to obtain from the Court of Appeal a decision that there was at any rate some scintilla of negligence, some prima facie appearance of carelessness displayed by the mere fact of injury, upon which the opinion of a jury should have been taken. It will not be forgotten that the facts of one case can differ very widely from the facts in another. Among the salient facts in Miss Beckh's case are the fact that what was performed was a sigmoidoscopic examination under an anæsthetic rather than a surgical operation in the ordinary sense, the fact that this took place apparently in her own home, and the fact that she herself paid the nurse. Her evidence was to the effect that the surgeon had said he would require a nurse, and that she asked him to choose one; on the day before the operation, she said, this particular nurse presented herself and made known her requirements, which included hot-water bottles. This evidence was hardly strong enough to establish that the nurse was the servant of the surgeon rather than of the patient.

Professional Secrecy.

A recent issue of the *American Journal of Surgery* contains a full-page advertisement in which the Post Office Department of Philadelphia offers a reward of 2000 dollars in connexion with the apprehension of one Frank Kiekart, a man alleged to be wanted by the Post Office Department for mail robbery and by the States of New York and New Jersey for murder. The advertisement contains two photographs of Kiekart, with a list of his eight aliases and a description of his appearance and habits. It adds that he is believed to be suffering from a fistula or other rectal ailment, that this is of so serious and painful a nature as to necessitate frequent medical attention, and that he is therefore likely to consult doctors or submit himself for examination at hospitals. The advertisement ends as follows: "It is requested that any doctor who may have treated a man for fistula or other rectal trouble, and who [*sic*] answers somewhat the description of Kiekart, communicate with the local post office officials or any of the undersigned."

This offer of a reward to physicians to induce a breach of the professional rule of secrecy raises an interesting problem of ethics in an unusually direct way. The doctor may well regard it as his first duty to give Kiekart such remedial treatment as his case requires, irrespective of any question whether he is a saint or a sinner. If a consulting-room or a hospital is simply to be a trap for a hunted man he will naturally hesitate to apply for the treatment which is necessary. It is usually laid down that an exception may or should be made to the rule of absolute professional confidence where a doctor knows that a crime is about to be committed, but this advertisement seeks to catch a criminal not to prevent a crime, though of course a criminal, if hunted and desperate, may be regarded as a man likely to commit a crime. In any case one may assume that a doctor, before taking any such step as is requested of him by the Philadelphia Post Office, would warn the patient and recommend him to surrender himself. English judges have occasionally reminded the medical profession that, in such circumstances as have been indicated, members have duties as citizens as well as duties as doctors. If a practitioner does his duty as a citizen he should not need the stimulus of 2000 dollars. The offer of a reward, indeed, in a journal circulating in hospitals, complicates the position, for the advertisement may be seen by some subordinate member of the hospital staff; it would be hard if a patient, protected by the professional tradition of confidence, should be betrayed by a hospital employee.

A False Declaration.

As a sequel to the now notorious channel swim
ax, Dr. Dorothy Cochrane Logan was summoned
the instance of the Director of Public Prosecutions
having wilfully made a statutory declaration which
s false in certain material particulars. The prosecu-
n expressly disclaimed any suggestion that the
fendant had attempted to obtain by false pretences
e reward which the *News of the World* had offered.
vertheless, as the Lord Mayor observed in fining
£100 with £10 10*s.* costs, she had committed an
ence akin to perjury; she was not, of course,
ng prosecuted for hoaxing the public, but she had
ated with contempt and ridicule a most important
l convenient part of our legal system by depreciating
value of a statutory declaration.

The Statutory Declarations Act of 1835 was passed
cut down the then existing multiplicity of oaths
l to substitute something a little less formal.
er referring to such varied matters as the oaths
ninistered at Oxford and Cambridge Universities,
oaths then taken by churchwardens and sidesmen,
oaths of applicants for patents and certain oaths
ler the Pawnbroking Acts, the Act of 1835 proceeds
offer facilities for the making of voluntary declara-
ns because (as the preamble to Section 18 recites)
may be necessary and proper in many cases not
ein specified to require confirmation of written
ruments or allegations, or proof of debts, or
the execution of deeds or other matters.
ordingly, it allows voluntary declarations in the
owing well-known form: "I, A. B., do solemnly
sincerely declare that . . . . and I make this
mn declaration conscientiously believing the
ie to be true and by virtue of the Statutory
clarations Act, 1835." This section provides
t the wilful making of a declaration false or
rue in any material particular shall be a mis-
neanour, but at this point the law is superseded
Section 5 of the Perjury Act of 1911, which lays
n the maximum penalty for conviction on indict-
nt as imprisonment for two years or fine or both.
Criminal Justice Act of 1925 allowed this offence
be dealt with summarily if the court thinks this
rse expedient in view of any representation made
the prosecutor or in view of the character and
ecedents of the accused, the nature of the offence
the absence of circumstances which would make
offence one of a grave or serious character.
ring these words in mind, the court found itself
to dispose of Dr. Logan's foolish escapade
marily and without recourse to maximum penalties.
vas stated on her behalf that, when the hoax was
ied out, she had no idea that any statutory declara-
would be required; when she went to the offices
he *News of the World*, it was added, the form of
aration was put before her for signature, already
pared. If these circumstances in any way mitigated
offence, the Lord Mayor presumably took them
account. Meanwhile certain newspapers, ungrate-
for the material which the incident has furnished,
been inclined to encourage the General Medical
ncil to stern disciplinary measures. What the
ncil—which has received encouragement or dis-
agement from similar sources before—might do
lled upon to deal with Dr. Logan's ill-considered
enture it would be improper to forecast; but
essional opinion does not in general judge harshly
ffences committed without unworthy motive.

OYAL LIVERPOOL CHILDREN'S HOSPITAL.—On
27th the recently reconstructed portion of the hospital
opened as a ward designed chiefly for the reception of
alty cases for observation and for post-operative care of
r operation cases for one or two nights. This had been
o be particularly necessary for the adequate treatment of
ren who had had tonsils and adenoids removed. The
ceremony was the unveiling of a cot endowed in memory
ueen Alexandra, who, for 60 years, had been Patroness
he hospital. The ward was then declared open and
ly a presentation was made to the matron, Miss Worsley,
he termination of her 20 years' service to the institution.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Local Government Administration in Northern Ireland.

THE Commission appointed by the Ministry of Home Affairs in April, 1924, to inquire into the conditions of local government in Northern Ireland, has now issued its report, a comprehensive document of 242 pages which bears witness to the wide extent and important character of the labours of the Commission. It deals with the poor relief services, the local administration of medical and public health services, asylum administration with recommendations regarding the dispensary system, and with public health administration in general. By far the most important change envisaged by the Commissioners is the reorganisation of the whole of the services on a county basis, as opposed to the present methods which are anomalous in many ways and involve widespread overlapping. Many of the recommendations of the Commissioners, therefore, centre on the way in which the new county administration, in all its branches, should be organised, administered, and supervised. The Commissioners wish the medical services to be entirely separated from any connexion with Poor-law administration, and they propose, therefore, that county committees and local relief committees should be established in place of the boards of guardians, that the workhouses should be replaced by a limited number of comfortable county homes for the reception of various classes in need of help, and that there should be definite medical supervision in these homes.

Apart from the general question of organisation under the new county scheme the report makes other recommendations for the improvement of the medical services of the country. As far as hospitals are concerned, it suggests that each district hospital should have a maternity ward, and that facilities should be provided for giving effect to child welfare schemes, and for the inspection and treatment of school-children. Recommendations are also made regarding the nursing services and provision for infectious diseases. The report deals at length with the question of tuberculosis, for the Commission was of the opinion that the present methods of treatment are too costly and on the whole ineffective in stamping out the disease. It recommends that sanatorium treatment should be provided for early cases, where there is reasonable hope of recovery; that advanced cases should be dealt with by the district hospitals; that more institutional treatment should be made for non-pulmonary forms of the disease; that the Tuberculosis Acts which are at present permissive should be made obligatory on all county health committees; and that power be given to local authorities to remove compulsorily to hospitals or sanatoriums all persons suffering from the disease, where infection is likely to occur.

The report contains many reservations, and among these perhaps the most important concerns medical benefit under the National Health Insurance Acts. There was great difference of opinion among the members of the Commission on this point, and ultimately the proposal to introduce these benefits was defeated by a large majority; a reservation favouring its introduction, however, was signed by several members and appended to the report.

As far as the financial aspect of the recommendations is concerned no pronouncements could be made, and the report does not attempt to give an accurate forecast of the effect of the suggested provisions on the rates. Some of the suggestions will involve increased expenditure, but, on the other hand, economies may be fairly expected, and much will depend on the efficient and prudent administration of the whole scheme.

The Commission was composed of 39 members sitting under the presidency of Dr. R. J. Johnstone,

M.P., professor of gynæcology in Queen's University, Belfast. The medical members were Prof. J. A. Lindsay, Lieut.-Colonel W. R. Dawson, Dr. David Gray, Dr. J. M. McCloy, Dr. W. McLorinan, Dr. H. S. Morrison, M.P., and Dr. J. D. Williamson.

Irish Free State Medical Registration Council.

The first meeting of this council was held on Nov. 1st in Government Buildings, Dublin. All the members were present. They were welcomed by Mr. R. Mulcahy, Minister for Local Government and Public Health, with who were Mr. E. P. McCarron, Secretary of the Department, and Mr. E. F. Stephenson, the Chief Medical Officer. Dr. Denis J. Coffey was unanimously elected President of the Council. The Council then considered arrangements for the establishment of the Register, which must be established not later than May 28th, 1928, and for drafting the necessary regulations under the Act. It is expected that meetings will be held each month for some time to come. The Council is fortunate in its choice of Dr. Coffey as President. He is familiar with the Medical Practitioners Act, as he had a large share in the negotiations which preceded legislation. Moreover, as a member of the General Council of Medical Education and Registration he has experience of the kind of work in which the Council will be engaged.

Ulster Medical Society.

The first meeting of the session was held in the Medical Institute, Belfast, on Oct. 27th, when the incoming President, Dr. J. C. Rankin, delivered an address in which special attention was called to the importance of the preliminary subjects in medical education.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Immigrants not Protected by Medical Certificate.

AN immigrant, having successfully passed the medical examination of the United States Public Health Service and having been found otherwise admissible, was for some reason referred back by the board of special inquiry to the medical officers. A second examination showed that the would-be immigrant was suffering from clonorchiasis, which comes under the category of "a loathsome or dangerous contagious disease." It was attempted, on behalf of the immigrant, to show that he had already been certified by the competent authorities to be free from all such diseases. However, a U.S. circuit court of appeals found that the first certificate had no finality. Since the certificate of the medical officers, which is necessary for exclusion on medical grounds, may be challenged by the alien, it is clear, the court holds, that it may also be challenged by the Government.

Persisting Casualties of the War of Independence.

This year's celebrations of the Declaration of Independence resulted in 195 deaths and 3179 injuries in 600 cities. Thirty-one of those killed were under 6 years of age, 122 between 6 and 20 years of age. No less than 16 deaths were due to the eating of fireworks by small children. Forty-eight deaths were due to the clothing being ignited by so-called harmless fireworks. The American Musuem of Safety, by which these figures are made public, points out that a yearly repetition of these fatalities may be expected, unless precautions are taken to prevent them. It is urged that instruction in the prevention of such accidents be made a part of the curriculum of every school.

Symposium on Feelings and Emotions.

Anyone who believes that psychology has attained to the status of a science should consult the papers presented at the symposium of psychologists in honour of the opening of a new psychological laboratory at Wittenberg College, Ohio. These papers were written by some of the most distinguish psychologists of Europe and North America professors from Harvard, Hopkins, Princeton, Toron and the larger State universities, from Vien Liepzig, Rostock, Paris, Geneva, Copenhagen, a Turin. Yet the reader will be forced to the melanch conclusion found in the paper by Prof. C. E. Spe man, of London University, that psychology ma little scientific progress and its deductions often la absolutely a scientific basis. The conference, wh was held from Oct. 19th to 23rd, was a triumph organisation, due to the energy of Dr. Martin Lut Reymert, formerly of the University of Oslo, and n director of psychology at Wittenberg College.

Efficacy of Vaccination Laws.

The American Association for Medical Progr has made an interesting study of the incidence small-pox in relation to the vaccination laws. number of States were divided into four grou according to whether their practice was (1) compuls vaccination, (2) compulsory vaccination restrict (3) compulsory vaccination according to option local health boards, or (4) compulsory vaccinat only in the presence of small-pox. During the per 1921–26 there were, in the States listed, 304,045 c of small-pox, resulting in 3710 deaths. The grou States in which vaccination is compulsory for al part of the inhabitants comprise 31 per cent. of population of the country and yet have suffered o 7 per cent. of the total incidence of small-pox. St where vaccination is restricted, for example, by inclusion of a conscience clause, constitute 10 cent. of the total population and have experien 24 per cent. of the small-pox incidence, and 30 cent. of the total mortality. It is, of course, admit that regulations are not enforced everywhere w uniform success, but the figures suggest that morbi and mortality from the disease are affected by S regulations.

ROYAL MEDICAL BENEVOLENT FUND

THE following are some additional cases relieved at last meeting:—

Widow, of L.R.C.P. who died in 1926. When her hus died the Fund grant, together with his Epsom and Goverm Pensions, ceased. Applicant tries to support herself by env addressing at which her earnings rarely exceed 10s. a Total help given £35 and £26 voted in quarterly instalm This grant is supplemented by the Royal Medical Benev Fund Guild who give 10s. a week.

Widow, aged 70, of L.S.A. who died in 1906. Applicant her three daughters and married son live together. E daughter, aged 46, who has an annuity of £20, is an epil Second daughter looks after the house; son, aged 43, ma one child, is an invalid receiving help from the B Legion and allows his mother £52 per annum. Youngest dau 32, is a dancing instructress and made £40 last winter, £ which she paid to her mother for her keep. Friends gave and applicant has the Old Age Pension. Rent and rates ar to £48 per annum. Previous help amounts to £81. Vote in quarterly instalments.

Widow, aged 59, of L.R.C.P. who died in 1904. Only in is rent from a house which amounts to £65 after dedu expenses for repairs. Rent, including fire and light, £4 annum. Asks for renewal of grant as her income is insuffi to meet her expenses and increased rent. Previous help Voted £10 in two six-monthly instalments.

Daughter, aged 64, of M.R.C.S. who died in 1890. U 1922 supported herself as a lady's companion, but owi ill-health had to give up work. Income from investr amounts to £52 per annum; relations give £4. Applicant not pay any rent but £5 for rates. Voted £15 in four qua instalments.

Subscriptions may be sent to the Honorary Treas Sir Charters Symonds, at 11, Chandos-street, Caven square, London, W. 1.

ANCOATS HOSPITAL EXTENSION.—The pressure Ancoats Hospital, Manchester, has become so severe— is a waiting list of 1000—that the committee of ma ment has decided upon extensions which will cost £10 A large adjoining site is to be acquired, upon which w erected casualty and pathological departments, two op ing theatres, wards for men, women, and children, 100 beds, and full accommodation for the extra nurses female staff.

Public Health Services.

TUBERCULOSIS IN BIRMINGHAM.

THE FUNCTIONS OF DISPENSARIES AND SANATORIUMS.

THE annual report of the chief tuberculosis officer r Birmingham (Dr. G. B. Dixon) shows a satis- ctory decline in the incidence of all forms of iberculosis, while a comparision of the five-year eriods, 1901–05 and 1922–26, shows a reduction of) per cent. and 67 per cent. in the mean mortality om pulmonary and non-pulmonary forms respec- vely. Both cases and deaths are still about twice frequent in the central wards as in the outer ring, it it is encouraging to note that the most rapid cline in the death-rate is taking place in the central ea.

Dr. Dixon gives seven reasons for this decline, e most important being "a higher general intelli- nce among the people," and a growing appreciа- n of the laws governing the maintenance of health. ie others, he says, include Koch's discovery of e bacillus and the work of the investigators who llowed him, the isolation of patients in institutions, struction given in the homes of the tuberculous d at sanatoriums, improvement in the food of the ople, and greater devotion to outdoor exercise ong both sexes. It seems unlikely, however, at the segregation of patients can at the present ne play any important part in the diminution infection, for in the Birmingham sanatoriums e average period of treatment does not exceed ee months for adults, while 40 per cent. of e patients discharged were classified as Group III. .e., were suffering from advanced disease at the ne of discharge. And though the instruction given dispensaries and elsewhere has doubtless had some luence in diminishing the cases of infection, it disconcerting to learn that in 1926 the health itors found that in more than 1000 cases a tuber- ous patient was sharing a bed with another son. It should be added that in Birmingham ery effort is made to rectify this deplorable state affairs and that 955 beds are at present loaned or hire in tuberculous families.

The statement that nearly 20,000 attendances re made at the antituberculosis centre "for atment alone" may well raise questions as to nature of the treatment provided and whether adequate return can be expected from the endance of the tuberculous at an out-patient ic. Experience suggests that a dispensary is re valuable when it is kept for purposes of con- tation. There are no short cuts to a diagnosis pulmonary tuberculosis in its earlier stages, and uberculosis officer who realises the importance the evidence to be obtained from the history of patient, who appreciates the need for a searching ical examination, and who has facilities for iography, will require at least half an hour for investigation of each new case. Usually more n one examination of the patient will be necessary well as repeated sputum and radiological tests in btful cases. The overworked general practi- ner, especially if his practice lies in an industrial a, cannot examine every patient complaining of spicious chest symptoms with the care that is essary if the earlier manifestations of tuber- osis are to be discovered. The value of the dis- sary lies in providing the general practitioner with information he requires without any serious upon his own time. If the dispensary is used an out-patient clinic the tuberculosis officer will l much of his time wasted in seeing a succession patients, most of whom are the victims of social umstances rather than of disease and for whom can do little. Nor will he approach the real sultation case with the freshness of mind required the investigation of problems which call not only skill, but for alert intelligence. Inflated atten- ces at dispensaries should therefore be avoided and treatment, except of certain definite kinds, should be discouraged in them.

It is noteworthy that among adult patients attending the antituberculosis centre, bacteriological support for the diagnosis was lacking in 68·7 per cent. Of children attending for a first examination and newly notified, no less than 194 out of a total 196 belonged to the "pulmonary tuberculosis T.B. minus" group, no sputum being available in 166. Apart from the very small group of children suffering from pulmonary tuberculosis of the adult type, the examination of the sputum is rarely possible and still more rarely helpful. The classification designed by the Ministry of Health applies to persons of all ages, though it is based upon evidence that can be obtained (with the exception noted above) only in the case of adults. The returns for pulmonary tuberculosis in children are therefore valueless.

Dr. Dixon supplies a brief report on the work of the Birmingham sanatoriums from which 1748 patients of both sexes and all ages were discharged in 1926. The average duration of stay for males was (as noted above) 61·4 days, for females 90, and for children 148. It is evident from these figures that, as a rule, the duration of treatment is strictly limited, and whilst it is true that a short period at a sanatorium is sometimes useful for educational purposes, it is equally clear that a brief period of improvement, followed by a recrudescence of disease on discharge, often leads to cruel disappointment, besides wasting public funds. Sanatoriums for adults should be reserved for patients whose social circumstances and clinical condition suggest that arrest of the disease is probable, and most of the patients on the registers of the tuberculosis dispensaries throughout the country can obtain only temporary benefit at a sanatorium. On the other hand, hospitals for the segregation of advanced cases are invaluable and more beds for these patients are urgently needed if the health of the next generation is to be safeguarded. In a great many cases, again, money would be better spent on providing home treatment, with financial assistance, than on admitting patients to sanatoriums for brief periods under tuberculosis schemes.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1926 statistics of nine counties:—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Diarrhœa, &c., under 2 years.	Infant mortality.	Maternal mortality from childbirth.

* Excluding "other respiratory diseases."

Derbyshire.

Dr. W. M. Ash reports that an additional maternity home has been erected by the county council at

Ashbourne. It contains a public six-bed ward, three private single-bed wards, a labour ward, and an isolation room entered directly from the terrace. A plan of the building is given. To meet the puerperal fever regulations, it is considered that institutional treatment will be preferable to the provision of nurses for domiciliary treatment and arrangements are being made accordingly. Dr. Ash has much to say about the centrifugal movement of the population and the consequent need for country planning. Chains of houses and factories spring up along main roads and rivers and streams have to take their sewage and trade wastes. Scientific sewage purification has not been able to keep pace with this movement, and legislative action is urgently needed to prevent the beauty of the country being destroyed. Many clean milk competitions are being arranged in the county by the agricultural organiser, the awards being based on sediment tests and bacterial counts. A meeting of all the sanitary inspectors in the county was held to discuss the Milk and Dairies Order of 1926, and is expected to give valuable results in securing uniformity of standards and procedure. The following work was done under the Milk Act and Order: animals slaughtered 749, of which 678 had advanced tuberculosis, 65 had tuberculosis not advanced, and 6 were not tuberculous. During the year 372 milk samples were examined for tubercle, and 41, or 11 per cent., gave a positive result.

Bretby Hall orthopædic hospital was opened in April for 50 cases of bone and joint tuberculosis in children, and an arrangement has been made with the education committee for the reception of 50 more children suffering from crippling defects of non-tuberculous origin. The conveyance of children to and from the orthopædic clinics is a difficulty, and Dr. Ash makes an appeal to those who have motor-cars and leisure to lend a hand. There is seldom more than one child in a village in need of such assistance. The notification of tuberculosis, although better than it was, is still very badly carried out. The school report shows that out of 27,048 children examined 5475 were referred for the treatment of ear, nose, and throat defects, and 1476 were operated on for tonsils and adenoids. Two satisfactory features are noted—first, that there is a marked decrease in the number of children suffering from otitis media; and, second, that an increasing number of children below the school age are brought up for treatment.

The investigation of goitre still goes on and confirms Dr. Ash in his view that lack of iodine is not the cause of goitre in Derbyshire, that it is impossible at present to prove the presence of iodine starvation in the population, and that the indiscriminate use of iodine is dangerous. The available evidence in this county, he says, goes to show that goitre has some relation to the water-supplies, and that it is more prevalent among the population supplied with water from the limestone than in those supplied with water from the millstone grit. The investigation and experiments in Derbyshire have the advantage of being carried out by one observer, Dr. Philip Turton, so that in the classification of degrees of goitre the fallacy caused by the personal factor is eliminated.

Hampshire.

Dr. R. A. Lyster says the county council is the authority for the notification of births throughout Hampshire, with the exception of Winchester and Aldershot, and that the notification is well carried out. Only 1 per cent. of the births were unnotified during 1926, and every mother receives, in response, a pamphlet on the care of children. The county council have made an arrangement with the Winchester Maternity Society to acquire adjoining premises and fit out a maternity home with eight beds for the exclusive use of county council patients. The home was opened in March and 74 cases were admitted during the year. The Royal Hants Hospital admits abnormal cases for the council, and an antenatal clinic is held there twice a month to determine whether applicants are suitable for the hospital c for the maternity home. The county council als take four beds at the Mothers' Hostel, Epsom, at cost of £60 per bed, to which women are admitte with their babies, to be trained for domestic servic It is easy to secure suitable situations for the mother but not always easy to arrange about the bab In some cases the county council make hostel gran of 10*s.* per week for the maintenance of the babies the hostel when the mothers have secured wor Infant welfare centres have increased in numb steadily year by year. In 1917 there were 11, ar now there are 85. All of them are voluntary wi county council officers to form the nucleus of t staff. There are some 550 voluntary workers, ar it would be easy to obtain more for new centres the county council could furnish the nucleus sta The annual grant paid by the county council to the centres is only £600. In view of the puerpe pyrexia regulations, institutional treatment, path logical examinations at the county laboratories, a the services of the health visitors, who are all train nurses, have been made available, and the questi of a consulting obstetrician is under consideration.

The scheme under which expectant mothers w engage a midwife and desire to insure against the ne for having to call in a doctor is working satisfactori and is generally welcomed by the medical men the county. The tendency is for medical servic to be called in more frequently for the insured patien but the rough figures available up to now do r indicate much difference in cost to the county coun of insured and uninsured cases. About 45 per ce of the confinements attended by midwives w those of insured patients. The extension of the m wifery service through the county nursing associati proceeds more slowly than heretofore because t areas not provided for are comparatively isolat or in the nature of islands between the districts f existing nursing associations.

East Sussex.

Dr. A. G. R. Foulerton reports operations carr out under the Milk Acts and Tuberculosis Ord The county council have, as yet, only had mi herds inspected when there was an outside compla of tuberculous milk. From Sept 1st, 1925, April 30th, 1927, there were 19 such complai As a result 22 farms were inspected, 680 cows w examined, 68 had their milk specially tested, a ultimately 10 cows were shown to be giving tuber lous milk. Including these 10, 809 tuberculous c have been notified to the police under the Tubercul Order during the first 20 months of its operati Of these 795 were found to be tuberculous, 136 which had lesions of the udder. The number milch cows in the administrative county is 32,0 Dr. Foulerton suggests that 785 of these cows w notified to the police by the owners "either beca the cow was seriously emaciated or because it sho other obvious signs of disease, suggestive of tu culosis—in other words, because the cow was in s an advanced condition of tuberculous infection would render its milk seriously dangerous." At same time he appears to be desirous of showing t the introduction of the Order has been a gain f the public health point of view. The report, howe does not produce any evidence that the "advance cows were notified to the police at an earlier st of the disease than that at which they would h been sent to the knacker in pre-compensation day

Under the council scheme for maternity c 54 women were admitted to the Women's Hosp at Brighton, one to Crowborough Cottage Hospi and two to Tunbridge Wells Maternity Home. the 57 cases, 15 were admitted as labour emergenc 30 because antenatal observation had detec abnormalities, and 12 on account of unfavour home conditions. Considerable improvements h been effected at Darvell Hall Sanatorium, used joi by the county and the Borough of Hastings, and available beds have been increased from 75 to 93.

East Suffolk.

Dr. Bernard Wood-White reports the reunion of e public health and school medical services after separation of some six years, and that the health mmittee have accepted as a far-off ideal a scheme r a combined medical service similar to that in eration in a considerable part of the neighbouring unty of Essex. Dr. Wood-White shows how the unty could readily be divided into six areas, each th a population of about 30,000, in which one medical icer would act for the rural and urban district uncils and also as assistant county medical officer health. A serious pollution of the river Gipping s been caused by the waste from a large artificial k factory recently established at Stowmarket. e pollution is chiefly due to sulphur and sulphur mpounds and causes a strong smell of sulphuretted drogen. Steps taken by the company had caused ne improvement, but the trouble had not been noved at the close of the year. Dr. Wood-White es not seem very hopeful about the benefit likely be gained from the Housing (Rural Workers) Act, 26.

Up to 1926 there were no dairy farms in the county plying "designated" milks, but during the year ree owners have been licensed for Grade A milk. ree complaints of tuberculous milk were received m Lowestoft, but in no case was the veterinary pector successful in finding an offending cow. regards the production of cleaner milk, the con- vative attitude of the agricultural labourer is a iculty, and to cope with it Dr. Wood-White nks the sanitary inspectors should undergo a rse of instruction at an agricultural college the production of clean milk. Dr. Wood-White nks "the Tuberculosis Order cannot be called an questionable success and that numbers of definitely ercular cattle are not brought to the notice of veterinary surgeon." The number of cows ughtered under the Order during the year, for st and West Suffolk, was only 95; 7 of these fered from tuberculosis of the udder, 2 were giving k containing tubercle bacilli, 47 had tuberculous aciation, and 38 other tuberculous conditions. e cows slaughtered included all bovines and more n half were milch cows. There are in East Suffolk ne about 25,000 dairy cows. An outbreak of te infantile paralysis occurred in the small age of Dennington, with 15 cases and 4 deaths. e first case occurred in August, and most of the es in October. There seemed to be distinct dence of case-to-case infection. Notes of each of the ases are included in the report. The negotiations ut the establishment of a venereal diseases centre Lowestoft Hospital have reached a deadlock. sing associations have increased in number since l from 36 to 57, and now cover about two-thirds the county. Their nurses act as the agents of county council for the purposes of midwifery, ernity nursing, health visiting, and tuberculosis iting. The county council subsidises these associa- ns to the extent of £1900 a year, and in order to er the whole county an additional sum of at least 00 will be necessary. On account of financial gency the extension of the scheme is held up.

Fife.

r. G. Pratt Yule reports that of the four districts fermline and Kirkcaldy were affected by the strike. The district committees undertook feeding of expectant and nursing mothers and dren under 5 from May 1st, and spent over 1,000, as compared with an expenditure on this l of £144 for the months January to April. After most of this relief work was handed over to the sh councils. The health nurses in both districts rted that the families were well looked after and the children were better fed than in normal es, chiefly owing to their much larger allowance milk. One "bona fide" midwife was removed n the roll for failure to call in medical assistance a case of puerperal sepsis. During the last three quinquennia the deaths from puerperal sepsis have averaged 18, 14, and 12 respectively, and the deaths from other accidents of pregnancy 44, 75, and 51. Dr. Yule thinks the cases under the latter heading would often come more appropriately under the former. A small ward in the Kirkcaldy isolation hospital has been set aside for the treatment of puerperal sepsis. Insulin, ordered through the Board of Health, at a cost of 2*s.* per 100 units, is supplied to necessitous diabetic patients. Two males and eight females were so supplied during the year and one female was granted 10*s.* per week towards the cost of her special dietary. Houses are needed in the Cupar and St. Andrews districts, but the district committees have not so far provided any. In the Dunfermline district the need for houses continues in some mining areas, but may be modified as a result of the depression in the coal trade. With the approval of the local health authorities of the county a whole-time veterinary surgeon has been appointed for the purposes of the Milk Act. Steps are being taken to prevent the pollution of the river Eden by a beet sugar factory. At present the waste runs to a settlement pond of three acres, but the capacity of the factory is likely to be doubled, and continued watchfulness will be necessary.

Isle of Ely.

Dr. J. Pixton Walker describes among the special features of the year the better housing of his staff in the County Hall, the extension of mental deficiency work through a new voluntary association, and the fusion of the rural and urban districts of Whittlesey. Dr. Walker thinks the cutting down of the issue of cod-liver oil by tuberculosis dispensaries is a costly economy. The rivers Ouse and Lark are polluted by beet sugar factories at Ely and Bury St. Edmunds. Suggestions have been made to prevent the pollution at Ely by the provision of more baffles in the settling ponds and by the treatment of the effluent. In the Whittlesey urban district "44 householders draw their water from condemned wells and 27 draw their water from the Briggate river, where the town sewer discharges into the river." A case of midwifery attendance by an unqualified male practitioner was discovered in the Ely rural district a few days before the new Act came into force. In North Witchford R.D. a cow died on the roadway and the carcass was cut up and sold for human meat. Prosecution was successfuly undertaken for the technical offence of failing to give notice of slaughtering, and at the trial it was held that "slaughtering" did not end with the death of the animal, but included the preparation of the meat for human consumption.

Breconshire.

Dr. Herbert Davies reports that the nurses of the local district nursing associations perform the duties of midwife, school nurse, and health visitor. Midwives attended 957 live births and 56 stillbirths. The proportion of stillbirths to live births in the county was 5·7, which is unusually high. The treatment of tuberculosis is carried out by the Welsh Memorial Association, and a county council committee meets quarterly to consider the housing conditions of each person notified. Cases of overcrowding are reported to the local sanitary authorities with a view to securing the better housing of the patients.

Soke of Peterborough.

Dr. Christopher Rolleston gives in his report a full scheme for the working of the Housing (Rural Workers) Act of 1926, but his health committee have decided not to adopt it. Dr. Rolleston thinks the Act, if wisely administered, would confer untold benefits upon the countryside, and points out that the counties bordering on the Soke have already adopted it. Dr. Rolleston urges the advisability of the establishment of antenatal centres at Peterborough and Stamford. The county council has made arrangements with Stamford Infirmary for the reception of cases of difficult labour and of

puerperal fever for the two rural areas, but the council of the City of Peterborough, the one urban area, has "decided not to ask the Minister of Health at present to allow them to have power to have bacteriological examinations, hospital treatment, or trained nurses." Fifty-eight per cent. of the infant deaths in the county were due to congenital debility, and three infants received orthopædic treatment, suffering respectively from spinal curvature, club-foot, and spastic hemiplegia. Dr. Rolleston emphasises the difficulty of the agricultural labourer in securing dental treatment for the most important member of the home—the mother. Dr. Rolleston's work in his small county is largely clinical, and he gives the notes of cases of pulmonary tuberculosis treated by him by means of artificial pneumothorax. The cases number 28 and have been dealt with during the last ten years. Seven are in full work, three more in excellent health, including one woman who has gone through pregnancy; six are able to do some work, one in spite of the complication of heart disease; five others are in very fair health, including one who has successfully recovered from an operation for stone in the kidney; two are making satisfactory progress; one is doing badly; and four are dead. All the cases were advanced ones and many have lost the tubercle bacilli in their sputum under treatment.

Roxburgh.

Dr. M. J. Oliver says the occurrence of a false alarm of small-pox demonstrated the utter unsuitability of the wooden structure, scantily provided with furniture, bedding, and utensils, and unused for many years, for the receipt of patients. The country children had to be excluded from the high school at Hawick for the later months of the year owing to the prevalence of scarlet fever, and an outbreak of this disease, with 23 cases in different districts, was caused by a family who did not get medical advice for the original case. Dr. Oliver is not satisfied that our education system is doing anything to train up mothers who will require less supervision than the present generation. Maternal efficiency, he says, is more important for the health of the young than such conditions as poverty, underfeeding, or overcrowding. The education of good mothers is in the hands of the education authorities, while the sanitary authorities have to deal with conditions due to bad mothers. Newstead Hospital, serving the Jedburgh and Melrose districts, has been greatly improved during the year. The Kelso Hospital needs a motor ambulance. The services of the aural surgeon have been found invaluable. Dr. Oliver says everyone interested in dairy work and meat inspection understands the importance of obtaining the services of independent whole-time veterinary inspectors, and that the county council had practically succeeded in attaining this object by getting all the health authorities in a wide area to combine. Unfortunately, when it became known that the Board of Health had agreed to the appointment of part-time inspectors in Perthshire, one after another the authorities dropped out of the combine and the county council has had to fall back on part-time inspectors for each of its five districts. The farms only number some 70 to 80 and the milch cows in four districts (excluding Liddesdale) number under 1000. An attempt is being made to secure some uniformity by means of a subcommittee of the county council. The new by-laws have been approved and "imply a revolution in dairy work," and much patient work will be required to bring them into operation. The county sanitary inspector's description of the conflict between the "Uppies" and the "Doonies" in Ancrum village illustrates the difficulty of parish sanitary administration. The "Uppies" lose their water-supply when the service tank is low and favour an improved scheme and also a scavenging system. The "Doonies" have continuous water-supply without carrying it and tip their refuse over the river bank, and therefore care for neither of the things desired by the "Uppies."

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 29TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 19 (last week 200); scarlet fever, 2690; diphtheria, 1417; enteric fever, 74; pneumonia, 1112; puerperal fever, 3; puerperal pyrexia, 113; cerebro-spinal fever, 7; acute poliomyelitis, 25; acute polio-encephalitis, 3; encephalitis lethargica, 27; dysentery, 8; ophthalmia neonatorum, 91. There was no case of cholera, plague or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 25 (2) from measles, 4 (0) from scarlet fever, 6 (0) from whooping-cough, 41 (13) from diphtheria, 66 (9) from diarrhœa and enteritis under two years, and 64 (11) from influenza. The figures in parentheses are those for London itself. The number of stillbirths registered during the week was 238 in the great towns, including 44 in London.

The Services.

HONORARY SURGEONS TO THE KING.

Colonel Thomas Kay, D.S.O., T.D., Assistant Director of Medical Services, 52nd (Lowland) Division, Territorial Army (vice Colonel F. H. Westmacott, C.B.E., T.D.), and Colonel Reginald Ernest Bickerton, D.S.O., T.D., Assistant Director of Medical Services, 56th (1st London) Division, Territorial Army (vice Colonel A. D. Sharp, C.B., C.M.G., T.D.), have been appointed honorary surgeons to the King.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. A. G. McKee is promoted to the rank of Surg.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs.: W. H. A. D. Sutton (Prov.) and R. S. Dickie.

Lt. (on prob.) E. W. Hayward, from the secd. list, is restd. to the estabt.

Lts. (on prob.) W. F. Lane and T. F. M. Woods are seen under the provisions of Art. 205, Royal Warrant for Pay and Promotion, 1926.

T. F. M. Woods to be Lt. on prob.

ARMY DENTAL CORPS.

Capt. E. D. Batty resigns his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Capt. K. Simpson resigns his commn.

Lt. H. A. Eadie to be Capt.

Lt. R. E. Davie, late Cameronians, to be Lt.

INDIAN MEDICAL SERVICE.

Lt. J. F. Shepherd to be Capt.

Temp. Lt. Syed Mahmood Ali Khan to be Temp. Capt.

Lakshman Dass, Trilok Chand Puri, Sher Mohmed Khan, Mallick, Rewati Raman Bakhshi, Chandra Mani, Amar Singh Arora, Yadu Nandan Lal, Aziz Ahmed, and Keshao Balwantrao Gore to be Temp. Lts.

ROYAL ARMY MEDICAL CORPS EXAMINATION.

The next examination for commissions in the Royal Army Medical Corps will be held in January next. Application by intending candidates should be made to the Under-Secretary of State (A.M.D.1), the War Office, Whitehall, London, S.W. 1.

NAVAL NURSING SERVICE.

The medical members of the Consultative Board which has been formed to advise on matters concerning Queen Alexandra's Royal Naval Nursing Service, and of which the Queen is President, are: chairman, Surgeon Vice-Admiral A. Gaskell, Medical Director-General of the Navy; deputy chairman, Surgeon Captain R. W. B. Hall, Deputy Medical Director-General; and Surgeon Commander F. Lyvis Smith, an assistant to the Medical Director-General.

DIPHTHERIA AT CATERHAM BARRACKS.

We understand that it has been decided to close Caterham Barracks for three months on account of diphtheria. At present the cause of the outbreak cannot be traced and there seem to be only a few cases.

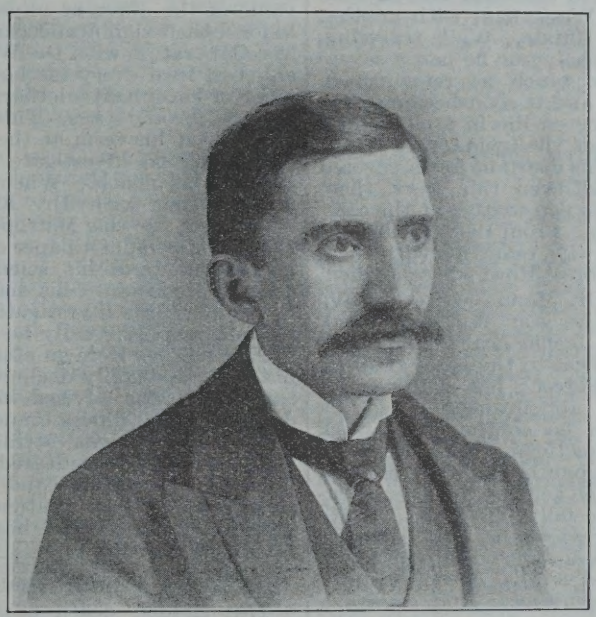
Obituary.

HENRY PATRICK CHOLMELEY, M.A., M.D.OXF.,

LATE ASSISTANT EDITOR OF "THE LANCET."

WE deeply regret to announce the death of Henry Patrick Cholmeley, which occurred on Sunday, Oct. 30th, at Forest Edge, Forest Row, after a brief final illness, at the age of 68. To many contributors of THE LANCET he was well known personally on account of his long service here on the editorial staff, while all our readers will have obtained information and pleasure from the varied and learned nature of his contributions during the past 30 years.

Henry Patrick Cholmeley was the only child of Mr. Henry Cholmeley, an officer in the H.E.I.C., by his wife, the daughter of Mr. J. Cumin, of Bath, and sister of the late Sir Patrick Cumin, of the Education Office. He was born in 1859 in Rangoon, and when he was an infant of 8 months lost his father, who was attached to a special mission in Burma as M.O. His mother, quite a young widow, returned to her father's house and lived there with her child for nine years. On his going to a preparatory school—Mr. Waterfield's well-known establishment at East Sheen—she took a house in the neighbourhood, and when he went on to Eton, to Mr. Warre Cornish's house, she again went to live near him. At Eton he rose to a high place in the school, and acquired a love of the classics which he never lost, retaining throughout his life a familiarity with both Greek and Latin literature which, to-day at any rate, is quite unusual. He proceeded to Magdalen College, Oxford, and having decided to follow his father's profession graduated in arts and medicine, completing his medical training at St. Bartholomew's Hospital.



DR. H. P. CHOLMELEY.

He entered the medical school in 1882 and took the M.R.C.S. Eng. in 1886, graduating in medicine at Oxford in the same year. His medical teaching was largely received from Dr. James Andrew, from whom he derived his sound clinical insight and for whom he always maintained a high regard. He acted as house surgeon to Mr. Alfred Willett, and then for three months assisted Dr. Lewis Jones in the foundation of the first electrical department in the hospital. Always a strong Churchman and profoundly interested in Church history, he went at this period, to his great pleasure, on Archbishop Benson's preliminary mission to the Assyrian Church with Mr. Athelst n Riley, but here he suffered a severe breakdown, contracting haemoglobinuria in Persia. On restoration to health and return to England, he was for various periods M.O. to the Victoria Hospital for Children and the Kensington Dispensary, and for some time performed the duties of medical registrar at the North-West London Hospital.

On the expiration of these appointments he set up housekeeping with his mother, and went into general practice in Onslow-crescent, South Kensington. They will be remembered by many as delightful host and hostess, who kept their positions towards each other, and towards the friends of each other, with perfect affection, and yet with independence. The son's deference was always there through frequent arguments, and the mother's realisation of the son's learning never stopped a firm and humorous output of her own views. They made a common study of many books, and had a common delight in good music, and lived on terms of love and intimacy that words cannot exaggerate. But the experiment in general practice was never a success. Cholmeley was shy in manner, dry in speech, fine in sentiment, and impatient of patronage. His poorer patients and all in serious plight of any sort had his devoted service, and these were always able to detect beneath his reserve the deep sympathy with them and the willingness to spare no effort. But for the routine of medical practice he had little aptitude, and to patients whose cases presented no points of pathological or therapeutic interest he never seemed a sufficiently serious adviser. He was impatient of fussiness and selfishness, and, though the kindest of men, he grudged expenditure of time in the rôle of mere comforter, and was no expert in concealing his feelings. So after less than ten years in practice he retired, and joined the staff of THE LANCET in 1896, being shortly afterwards appointed assistant editor, in collaboration with the present editor. Our illustration depicts him as he was at this date.

At THE LANCET his work, both within and without the office, was untiring and of a very varied nature. For the duties of a sub-editor he had a great distaste and, indeed, he was quite unfitted for them. There soon became no question of expecting him to prepare contributions for the press in any orderly way, or to conform closely to any official pattern. But he was a first-class judge of literature, general and medical, and in both fields his range of reading had been catholic, while his power of recalling what he had read and where he had read it was remarkable, especially as his references were drawn from such varied sources. Not a facile writer, his leading articles and editorial communications were produced with difficulty, and seldom gave satisfaction to his fastidiousness, but his accuracy was unfailing, his approach to a subject was logical, and the ideals that he put forward were always lofty yet never priggish. As a reviewer he was generous to all writers save the pretentious, and those who simulated a scholarship or culture which they did not possess. Many of his notices of books took the form of little essays on the subject matter, in which he would give reasons for his judgments, a procedure which would sometimes lead to letters from the writers to their unknown critic, seeking further information. This would usually occur when the work was one of medical history, in which he was deeply read, as his own contribution to this branch of study shows. For Cholmeley's work, "John of Gaddesden," is a model of what contributions to the long story of healing should be. His views were similar to those so profusely supported in the "Golden Bough," for he held that many popular ideas are survivals of ancient pathology which have taken longer to die out among the public than among members of the medical profession, but in which the foreshadowing of later discoveries and methods can be definitely traced;

and he urged, for this reason, that the exponents of early pathology should be approached with real respect, pointing out that, in the light of new facts discovered and of new principles formulated, the fancy of the past may become fact of the present. In this spirit he wrote the life of John of Gaddesden, the first English court physician, who flourished at the end of the thirteenth century, and who compiled the Rosa Medicinæ from Greek, European, and Jewish sources, illustrating the learning of his predecessors by personal observations drawn from extensive practice. The book illustrates the general scientific equipment of a physician of those far-off days, with its reliance upon superstitions, and none the less upon clinical observations, and justified Cholmeley's thesis that the empirical statements were not necessarily false because they were formerly saddled with an explanation later seen to be erroneous.

After the death of his mother in 1903, Cholmeley lived for a time in Portland-place with his great friend, Gustave Schorstein, but Schorstein, it will be remembered, fell a sudden victim to diabetes, and in 1908 Cholmeley went to live at Westerham with another intimate friend, Dr. Arthur Maude. While travelling in Italy with Dr. Maude in that year he had a severe attack of pneumonia, after which he remained in exceedingly delicate health, and it soon became clear that he could no longer carry on life in a city office. So to our great regret he left the inside staff of the paper, though to the day of his death he never severed his connexion with us, and even this week there appear contributions from his pen written at the commencement of his fatal illness. From 1908 onwards he lived with Dr. Maude and his wife, removing with them in 1914 from Westerham to Forest Row, where he died.

Of their life in Sussex Dr. Maude writes: "We moved to Forest Row in the year of the outbreak of war, and in spite of his feeble health Cholmeley acted as civilian medical officer to the large artillery training camp on Ashdown Forest; but at the end of six months he found this appointment taxed his strength too much, though he continued to work steadily in multifarious directions where he could fill the gaps left by those gone on military service. Though all his time with us he kept up his fine knowledge of the classics, especially of Virgil, wrote occasional articles, mostly reviews for THE LANCET, and read omnivorously. He interested himself much in gardening, and developed a love of flowers into a sound knowledge of horticulture. And always a keen Churchman, he took an active part in the ecclesiastical matters of the neighbourhood, where his real acquaintance with Church history, music, and Christian art in all countries, gave his opinions and counsel just value. His death will be keenly felt by many in Forest Row, where his piety, learning, and gentle charm of character were widely appreciated."

Cholmeley always described himself as a happy man, and the sources of this happiness lay in his own fine character. Much learning left him modest, a truly charitable nature freed him from all bitternesses, he had no jealousies, and his trained mental qualities gave him the power to enjoy beauty in all forms. To his colleagues at THE LANCET, in every department, his death has been a real source of grief.

S. S. S.

ERIC WEMYSS FULTON, M.B., CH.B. ABERD.

WE regret to announce the death of Dr. Eric Wemyss Fulton, which occurred from lobar pneumonia at the early age of 27. In him neurology has lost a brilliant young exponent.

Eric George Alexander Wemyss Fulton was the son of Dr. Thomas Wemyss Fulton, the superintendent of scientific investigations on the Fishery Board of Scotland. He was born in Aberdeen and educated at the Aberdeen Grammar School. Proceeding as a medical student to the University, he graduated as M.B., Ch.B. in 1924, and from the beginning of his career as a qualified man was drawn to the study of neurology. After filling certain resident appointments he came to London as clinical assistant at the West End Hospital for Nervous Diseases, and at that hospital was successively house physician, resident medical officer, and in-patient registrar. At the time of his death he still retained connexion with the institution, for he was doing honorary work as clinical assistant in the out-patient department and was following up various groups of cases. In the meantime he had been appointed resident medical officer in charge of the post-encephalitis lethargica unit at the Northern Hospital of the Metropolitan Asylums Board (Winchmore Hill) under the Ministry of Health. Here he devoted himself with great zeal to the study of the problems involved in cases of this disease which present to-day so much difficulty both in diagnosis and prognosis. Some of his observations and their results have been embodied in the reports of the Metropolitan Asylums Board, though much of his work still remains unpublished. The same may be said of his work at the West End Hospital, where he was engaged upon a series of researches into the comparative diagnostic value of the different physical signs of upper neurone lesions, their significance, and explanation. Here also in collaboration with Dr. Worster-Drought, he investigated in turn every method advocated for the treatment of encephalitis lethargica both during the acute and the chronic stage. This work extended practically throughout his term at the hospital, and he was still continuing to investigate the later methods at the time of his death. When he was taken ill he was collaborating with Dr. Kinnier Wilson, consulting neurologist to the Metropolitan Asylums Board, in the preparation of a paper on clinical post-encephalitic phenomena, and his scientific keenness may have actually determined his death, for so insistent was he to complete his investigations that he did not cease working until virtually he collapsed. Only last year he had suffered from an attack of broncho-pneumonia but he had steadily declined at that time to take the rest which was advised him by his doctor, and no doubt his final illness found him a ready victim.

Eric Fulton was attractive both in mind and manner. He had endeared himself to all with whom he came in contact, and his death will be deeply regretted by both patients and colleagues alike. Certainly if his life had been spared a great scientific future lay before him.

ROBERT LOWIS ROUTLEDGE, M.B. DURH.

THE sudden death of Dr. R. L. Routledge, of Haydon Bridge, as the result of a motor-cycle accident while on his rounds, adds another to the list of tragedies whereby medical men have lost their lives in the pursuit of their avocation. Born at Rookhope in Weardale 53 years ago, he studied medicine at the Newcastle School and graduated as M.B., B.S. at the University of Durham in 1899. For a time he acted as one of the medical officers of the Newcastle Dispensary, and afterwards assisted Dr. Gray, of Stanhope. About 23 years ago he went to Haydon Bridge where he took over the practice of the late Dr. Callender. Dr. Routledge soon became well known and highly respected in South Tynedale for his practice comprised a scattered agricultural district. He was medical officer for the district and took a great interest in everything which concerned its welfare. A strong supporter of outside sports he was actively associated with the Haydon Bridge cricket club. At the outbreak of the late war he joined the 4th Battalion Northumberland Fusiliers (Territorials), and served throughout the period of hostilities. Afterwards he took a great interest in the local branch of the British Legion. A colleague writes of him:—

"Routledge was always cheery and optimistic, but unassuming and very human, content to minister to his patients and to find recreation in his own home circle and in promoting the welfare of his own village. He will be greatly missed and mourned far and wide, and not least in many a lonely homestead, for he was kindness itself to the poorer patients."

He leaves a widow and one son, who is studying for his father's profession.

Correspondence.

"Audi alteram partem."

THE USE AND MISUSE OF DENTAL SKIAGRAMS.

To the Editor of THE LANCET.

SIR,—Dr. Badcock's letter in your issue of Oct. 22nd ises a question of the utmost importance to both edical and dental practitioners. Very few would isagree with the statements he makes, but the issue much wider, I believe, than the interpretation of ental radiograms. The relationship between the octor and the dentist certainly could be improved. greater knowledge of dental pathology would ppear to be the solution for all practitioners. The entist cannot know a special form of pathology ithout being more widely acquainted than at present ith the general principles of the subject. The medical ractitioner has little opportunity of acquiring nowledge of dental diseases. The curriculum for ny examination does not demand such knowledge, nd, if demanded, hardly any examiner under the resent arrangements is capable of conducting such n examination.

The number of medical students attending the ntal departments of the hospitals for information, yond that of extraction of teeth, is remarkably w. In fact for the most part, medical men know thing of dental diseases or their pathology. The mmonest interpretation is that discoloration nstitutes disease; frequently have I known a tooth ained black by the application of nitrate of silver be regarded as the worst tooth in the mouth. ese remarks may be thought too severe, but I would t have them so interpreted, for until recent years ly the few have regarded pathological changes nnected with the teeth as of great importance.

What seems to have happened is that the medical actitioner, possessing in radiograms his only form information upon dental conditions, has credited em with an excessive value, whilst the dentist th a limited knowledge of pathology has done the me. Stereoscopic radiograms, when obtainable, e of greater value than simple films or plates, but ch is obtained through such a thickness of bone at unless a marked change has resulted, little formation can be derived.

In the future some knowledge of dental conditions ust be acquired by all medical men. The real ue, therefore, is educational. Can the curriculum extended? I feel sure the time will come when all ecial departments will have to be attended and a parate examination conducted upon the elementary nciples of each of these special subjects.

I am, Sir, yours faithfully,

W. WARWICK JAMES.

Park-crescent, W., Nov. 1st, 1927.

HIRSCHSPRUNG'S DISEASE IN ADULTS.

LIVER DIET IN ADDISON'S ANÆMIA.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 29th Dr. S. Harold okson described an interesting case of Hirsch- sprung's disease resulting from achalasia of the al sphincter in a man of 69. He states on my thority that the disease is very rare in individuals er 30 and he was unable to discover any recorded e after the age of 40. It may therefore be of erest to record the fact that since 1922 we have had der observation five males, aged respectively 9, 41, 61, and 42, and two females, aged 34 and 50, h typical radiological and sigmoidoscopic signs of gacolon (so-called Hirschsprung's disease) secondary achalasia of the anal or pelvi-rectal sphincter. ne of the cases required operation.

Our experience of the treatment of Addison's anæmia by liver diet fully confirms that of Dr. J. H. Anderson, and Dr. E. I. Spriggs reported in your issue of Nov. 5th. We first tried it in 1925 after reading the paper by Bobscheit-Robbins and Whipple in the *American Journal of Physiology*, in which they described experiments showing the favourable effect of liver given by mouth as a stimulant to blood formation in artificial anæmia in animals. Unfortunately we gave insufficient to produce any definite results. After the appearance in August, 1926, of Minot and Murphy's first paper on the treatment of Addison's anæmia with large quantities of liver we have given this diet in about a dozen cases, in addition to the administration of hydrochloric acid and the adoption of means to overcome the oral and intestinal infection. The results have been uniformly good; two or three patients, who would probably have died under the old régime, have recovered. It may be worth adding that raw liver sandwiches can be made very palatable by the addition of anchovy paste.

Unfortunately, the liver diet appears to have no effect on the associated nervous disease—subacute combined degeneration of the spinal cord.

I am, Sir, yours faithfully,

New Lodge Clinic, Windsor Forest, Nov. 7th, 1927. ARTHUR F. HURST.

PAYMENT TO HOSPITALS FOR MOTOR ACCIDENTS.

To the Editor of THE LANCET.

SIR,—The reply of Mr. P. T. Carill-Worsley, vice-chairman of the Norfolk and Norwich Hospital, will be read with great interest. From it is to be gathered that the statement in the report printed on p. 892 of your issue for Oct. 22nd was incorrect when it said "a private practitioner . . . could send his bill to an insurance company" for attendance on a motor accident victim and that consequently, by putting these persons in private wards, the hospital authorities could do the same.

There is no analogy between a voluntary hospital and a private practitioner. The former is a charitable institution and the latter is not. The former, in making any claim on a victim, would have to prove that a contract existed; in the case of the latter it is always inferred. What one understands to be the present position is that a voluntary hospital, *being a charitable institution*, cannot uphold any claim on a victim directly or indirectly for services rendered, unless that victim makes request, verbally or in writing, in advance, to be admitted either as a paying patient in the ordinary wards or to the private wards or buildings, and that placing him in the private wards rather than in the public wards without any such request expressed previously, will not reduce the expenses, but rather increase them, besides using up a much more limited space. If this is so, the only apparent way to alter the situation would seem to be to obtain legislation. May not the insurance companies say, when asked to pay for private ward treatment, that voluntary funds are intended for accidents and emergencies, and if they are not sufficient they should be increased; and if you have been placed in a private ward, and the hospital has thereby incurred expenses of an increased nature, that is not our concern?

The Norfolk and Norwich Hospital authorities propose to adopt the practice of placing victims—one concludes in all ranks of society—in private wards in order thereby to appeal to the generous instincts of insurance companies, which, after all, are business concerns. Would it not be as well, before this line of action becomes general, to ask the Hospital Association to state a case for counsel's opinion, whilst, at the same time, approaching the body representative of insurance companies in order to discover whether they would consider favourably the proposed procedure?

I am, Sir, yours faithfully,

Hove, Nov. 8th, 1927. E. ROWLAND FOTHERGILL.

MORBUS MACULOSUS NEONATORUM.

To the Editor of THE LANCET.

SIR,—The ætiology of this disease is obscure. It does not, as far as I know, appear in epidemic form; nor can I find any record of its appearance in association with a hæmorrhagic type of a specific infectious disease. On that account the following experience in my practice may be worth recording. On April 18th, 1927, I delivered a primipara of a healthy female child, the labour being normal and short. On the 21st the child developed morbus maculosus, and died next day in convulsions. On August 8th I attended, in the same house, a sister, aged 12 years, of this woman. She was suffering from severe hæmorrhagic diphtheria, and, in spite of immediate treatment at home and in hospital, died a few days later. There seems to me to be a possible relation between these two cases.

I am, Sir, yours faithfully,
W. MCC. MACPHERSON.

Birmingham, Nov. 8th, 1927.

INTERMITTENT CLAUDICATION: THE USE OF HEAT.

To the Editor of THE LANCET.

SIR,—The admirable paper by Dr. Wilson Gill and Dr. Newell Moss in your issue of Oct. 29th illustrates the effect of heat in widening a contracted arterial bed; and also illustrates the choice that often lies between local and general applications. For intermittent claudication I have long been accustomed to use a leg bath of hot air (180°–250° F.) with good and lasting effect.[1] Not only is the circulation in the limb greatly increased, but the body temperature often rises to 100° or 101° F., and the tissues are flushed with warmed blood. In patients with a generally subnormal temperature this may well be beneficial, as we find is the case after a course of hot baths or packs. The authors have observed that widespread or general diathermy with large plates relieves a local spastic condition. There is much to be said for both local and general applications of heat in vasomotor hypertonia, and both obviously have their uses.—I am, Sir, yours faithfully,

London, Nov. 2nd, 1927. R. FORTESCUE FOX.

SKIN GRAFTING FOR X RAY BURNS.

To the Editor of THE LANCET.

SIR,—The following will be of interest to those suffering from X ray burns and their consequences, and to those who have patients under their care from the same causes. About 20 years ago I had a large amount of X ray treatment given to me for psoriasis on the hands, with the result that about four years ago an ulcer developed, which became epitheliomatous. This was cut out in January, 1926, and an attempt to skin-graft completely failed.

In June of the same year the epithelioma returned, and was again cut out, leaving the wound to heal by cicatrisation. Again, in March of this year an epitheliomatous ulcer appeared. I had the opportunity of consulting Prof. Holzknecht, of Vienna, who himself has had many operations for X ray damages. He sent me to Dr. Gilmer, of Munich, who had operated on him four times, and to whom he considered he owed the saving of a large part of his hand. Dr. Gilmer has for 20 years studied these X ray destructions, &c., and methods of direct skin-grafting after removal of the affected tissue, however deep. I was three weeks in Munich under his care, with the result that where I had an epitheliomatous ulcer and a large, threatening scar, now I have quite good skin, which is rapidly becoming not only normal, but has entirely replaced the skin in the affected area.

I had the opportunity of seeing and hearing of many of his cases, and in some of the worst X ray burns involving large areas of skin, as well as epitheliomatous ulcers, complete cures resulted. His method is direct grafting under conduction anæsthesia and without antiseptics of any kind. his special experience and after-care of these cases are certainly most remarkable in their results. I feel it my duty to let others who are suffering from the after-effects of X ray burns, with perhaps the same hopeless outlook I had, know that there is a very real and successful method of cure.

If it would aid any medical men I will gladly show them my hand.

I am, Sir, yours faithfully,
EDWARD D. MADGE, M.R.C.S., L.R.C.P., L.S.A.

60, Brompton-square, S.W., Oct. 30th, 1927.

"SANE ENOUGH FOR SENTENCE."

To the Editor of THE LANCET.

SIR,—Under this heading in your issue of Oct. 29th you deal with the case of an inmate of the Three Counties Mental Hospital sentenced at the Bedfordshire Assizes for assaulting a member of the hospital staff and you suggest "there must be something wrong with the law when an asylum inmate is sentenced as a sane man." You then go on to say: "This and other instances raise the old disquieting doubt whether the law courts do not sometimes deliberately ignore the medical history of accused persons instead of obtaining the utmost possible information before passing sentence."

If your columns are not closed to the mere layman may I put an opposite point of view to your readers? But, first, let me state that it is now admitted by the Board of Control that the asylum inmate (whose name was Isaac Mitcham) was discharged from certificate on August 17th last, though the fact was withheld from him, was not available to counsel, and was apparently not even known to Mr. Justice Swift when he passed sentence. If there is a duty incumbent on the law courts to obtain the medical history of a case before passing sentence, surely there is a double duty incumbent on members of the medical profession to obtain adequate information before certifying. Yet in the case of Mr. Mitcham and of Mrs. De Frevil which took place within a few months of each other in the summer of 1926, any inquiry whatever would have established that within a few hours of certification they were in consultation with their solicitors on the family disputes involved in both cases. The solicitors concerned could have given indispensable evidence which in the opinion of most laymen would have rendered certification utterly impossible. More, of course, will be heard of the Mitcham case, but meanwhile it has raised in the public mind the only disquieting doubts as to whether some medical men do not deliberately ignore the previous history of their patients instead of obtaining the utmost possible information before certifying.

I am, Sir, yours faithfully,
R. MONTGOMERY PARKER,
Chairman, National Society for Lunacy Reform.

60, Avenue Chambers, Southampton-row, W.C.,
Nov. 7th, 1927.

POSITION OF THE LONDON HOSPITALS.—King Edward's Hospital Fund has just issued its annual statistical report on the income and expenditure of the 134 London hospitals which it assists. During 1926 the number of available beds increased by exactly 300, making 14,470 in all; there were 6000 more in-patients, the total number being over 200,000; and out-patients' attendances increased by nearly 300,000 to 7,455,000. The total cost of working was £3,058,000, £70,000 more than in 1925. Income increased by over half a million to £3,019,000, leaving a deficit of £39,000. Fifty-five hospitals had deficits. The average cost per occupied bed in the teaching hospitals was £234. Of the total expenditure, 19·2 per cent. was derived from investments, and 32·1 per cent. from patients' payments and other receipts on account of services rendered. Voluntary contributions, including legacies, produced 46·8 per cent.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The Raymond orton-Smith Prize has been awarded to Mr. V. B. Wiggles-orth, B. Chir.; proxime accessit, Mr. A. E. Roche, M. Chir.

UNIVERSITY OF LONDON.—The University Medal Branch IV. (Midwifery and Diseases of Women) of the D. Examination held in July, 1927, has been awarded to . Harold Burt-White, of St. Bartholomew's Hospital.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND RGEONS OF ENGLAND.—At the Final Examination held m Oct. 4th to 25th the following candidates were proved in the subjects indicated, but are not yet eligible diplomas:—

Medicine.—Dorothy G. Angus, Royal Free; G. D. Augenlicht, Westminster; Julia C. H. Avery, St. Mary's; Gertrude C. Banks and Ruth Bocock, Royal Free; Lilian M. C. Clopet, Cardiff; P. J. Cowin, St. Bart.'s; Pera R. C. Crawford, Royal Free; J. H. Cullinan and R. G. de Kock, Guy's; M. M. Dey, Leeds; J. F. Duesbury, Birmingham; H. Epstein, Guy's; R. Evans and J. D. S. Flew, Univ. Coll.; Christina Gibson, King's Coll.; J. C. Gregory, Univ. Coll.; C. E. Hagenbach, St. George's; D. V. Hague, Birmingham; R. L. Harward, Guy's; Anna M. Hilliard, Toronto; N. M. Hodivala, Bombay and London; M. C. Hounsfield, St. Bart.'s; Josephine M. Howells, Westminster; Dorothy M. James, Cardiff; H. Kaitz, Guy's; R. A. Kennedy, St. Thomas's; T. C. Kohler, Adelaide and London; Marie Krestin, Charing Cross; B. A. Lamprell, King's Coll.; R. R. Leaning, St. Mary's; W. E. B. Lloyd, Cambridge and St. Bart.'s; W. J. Lloyd and H. A. McGregor, St. Bart.'s; Olive S. May, King's Coll.; Margaret I. Meacock, Westminster; C. F. Moore, St. Bart.'s; O. N. Morris, King's Coll.; Ella M. Oswald, Royal Free; Irene A. Papenfus, Univ. Coll.; C. D. Politeyan, Cambridge and St. Thomas's; Dorothy K. Reynolds, King's Coll.; T. M. Robb, Guy's; W. J. M. Sadler, Univ. Coll.; G. Steinberg, Bristol; K. G. Sugden, St. Bart.'s; J. P. Thyne, King's Coll.; B. Timothy, London; W. R. van Langenberg, Middlesex; G. P. A. van Rossum and H. O. White, St. Bart.'s; F. Williams, Cambridge and London; A. Wilson, Leeds and J. S. Zidel, St. Bart.'s.

Surgery.—J. McL. Anderson, Charing Cross; W. R. Ashby, Cambridge and St. Bart.'s; A. L. Basham, St. Thomas's; N. Bissada, Manchester; W. Buckley, St. Bart.'s; F. Bush, Univ. Coll.; J. D. Cambrook and G. C. Campbell, Guy's; T. H. Carr, Leeds; S. S. Chesser, St. Thomas's; T. L. Cleave, Bristol; R. E. P. Cohen, Birmingham; W. H. Collins, London; C. F. J. Cropper, King's Coll.; C. H. Dale, St. Bart.'s; T. C. Dance, Birmingham; D. E. Davies, Liverpool; E. R. L. Davies, Cardiff; E. L. F. de Mel, Ceylon and Univ. Coll.; M. M. Dey, Leeds; A. Dodd, Liverpool; M. R. Doyle, St. Thomas's; L. L. Eksteen, Liverpool; M. M. El Toubi, Sheffield; M. J. Evans, St. Bart.'s; H. T. Flint, Westminster; J. P. Fraulo, Guy's; J. H. P. Games, Univ. Coll.; A. P. Gaston, St. Bart.'s; A. M. Ghaith, Birmingham; B. H. Gibson, St. Bart.'s; E. M. Goitein, Univ. Coll.; G. N. Grose, St. George's; H. W. Guinness, St. Bart.'s; M. M. Gyi, St. Thomas's; D. V. Hague, Birmingham; H. N. Hallam, London; N. F. Haslam, Birmingham; J. C. Hatrick, Univ. Coll.; W. Heard and L. Hennell, Middlesex; L. Hoffman, St. Bart.'s; E. R. Holiday, London; J. H. Hopper, St. Thomas's; E. J. Horn, London; I. M. Hughes, Manchester; W. L. Hurn and D. C. R. R. Jenkins, St. Bart.'s; I. J. Jones, St. Thomas's; H. Kaitz, Guy's; T. H. Khan, King's Coll.; G. G. King, St. Mary's; P. Kuhne, Lausanne; T. C. Larkworthy, St. George's; L. P. E. Laurent, Univ. Coll.; I. B. Lawrence, St. Bart.'s; J. Lieberman, Leeds; Olive T. Lloyd, Westminster; W. J. Lloyd, St. Bart.'s; Edna Lock, King's Coll.; S. McGladdery, St. Bart.'s; J. V. Macgregor, Univ. Coll.; K. W. Mackie, St. Bart.'s; W. A. N. Marrow, Middlesex; W. E. Mashiter, St. Thomas's; A. N. T. Meneces, Univ. Coll.; G. V. R. Mostert, Guy's; D. B. Mumby, St. Thomas's; J. J. O'Donoghue, London; Mary E. Pease, Univ. Coll.; A. L. P. Peeney, Manchester; A. E. Porritt, St. Mary's; R. W. Raven, St. Bart.'s; E. A. P. S. Rawlings, Charing Cross; R. W. Reid and W. G. Richards, St. Thomas's; M. Roberts, Liverpool; D. T. Robinson, Manchester; Esther Samuel, Madras; I. Schoub, London; H. A. Seidenberg, St. Bart.'s; J. Seidenberg and R. R. Shapland, Middlesex; L. Shillito, St. Thomas's; C. G. Sinclair, St. Bart.'s; P. D. B. Spence, Guy's; E. H. Spickett, Cardiff; G. S. Storrs, Cambridge and St. Thomas's; A. B. Swarbreck, Univ. Coll.; W. P. R. Swemmer, Guy's; I. C. C. Tchaperoff, St. Thomas's; J. E. Thomas, Cardiff; J. C. T. Tregarthen, Guy's; Elizabeth H. Waller, Charing Cross; A. R. Waterhouse, Leeds; R. N. Wilcox, St. Thomas's; E. A. Wood, Univ. Coll.; G. N. Wood, Guy's; J. L. M. Wood and J. A. Wood, Sheffield; Elsie E. Wright, St. Mary's; and N. R. W. Wynn-Williams, Middlesex.

Midwifery.—C. Ahluwalia, Charing Cross; Sofia Antonovitch and Mabel A. Baker, Royal Free; S. W. Barber, St. Bart.'s; Ellen M. Barnes, Univ. Coll.; G. Bellman, St. George's; H. Bernstein and J. R. Bond, Univ. Coll.; E. W. Bowskill, Manchester; J. W. Bromley, Cambridge and London; Nellie Brown, Westminster; C. E. S. Bullen, Leeds; H. L. Burke, Northwestern Univ.; D. W. E. Burridge, Leeds; F. Bush, Cambridge and Univ. Coll.; E. O. Butler, St. Thomas's; J. D. Cambrook, Guy's; A. N. Cameron, Liverpool; G. G. Cameron, Guy's; G. Campbell, Oxford and St. Thomas's; G. C. Campbell, Guy's; S. S. Chesser, Cambridge and St. Thomas's; T. L. Cleave, Bristol; F. Clifton, Cambridge and St. Thomas's; L. I. Cohen, London; E. T. Conybeare, Guy's; B. W. Cooke, St. Bart.'s; O. J. C. Cotton, Cambridge and St. Thomas's; C. H. Dale, St. Bart.'s; L. E. Daniel, Madrid and St. Thomas's; C. D. D. de Labilliere, St. Bart.'s; Claire de M. Dorey, St. Mary's; R. C. Dracup, St. Thomas's; J. F. Duesbury, Birmingham; J. C. E. Dusseau, Toronto; F. W. Earle, Liverpool; J. L. H. Easton, King's Coll.; Y. S. El Kommos, Cairo and St. Bart.'s; Marguerite M. Fenn, Royal Free; J. D. S. Flew, Univ. Coll.; R. B. Floyd, Cambridge and Manchester; E. C. I. Foot, Sheffield; Cecilia F. Fox, Bristol; T. R. Gaha, St. Mary's; A. P. Gaston, St. Bart.'s; Dorothea L. Gee, Royal Free; Caterina P. Giles, Cambridge and King's Coll.; F. N. Goggs, St. George's; Joan Goodger, Charing Cross; J. C. Gregory, Univ. Coll.; Gwendoline E. Grove, St. Mary's; E. Hacker, London; W. F. L. Hannay and H. N. W. Harley, Guy's; W. G. Harvey, St. Mary's; R. L. Harward, Guy's; N. F. Haslam, Birmingham; J. C. Hatrick, Univ. Coll.; Helen M. Herbert, Royal Free; R. T. Hicks, Univ. Coll.; Anna M. Hilliard, Toronto; J. M. Hulett, Guy's; Muriel S. Hulke and J. G. H. Ince, Univ. Coll.; D. C. R. R. Jenkins, St. Bart.'s; M. K. Jilani, Liverpool; Florence H. Johnson, Oxford and Univ. Coll.; Margaret L. Jones, Univ. Coll.; Emma J. King, Royal Free; S. E. Knowles, Guy's; H. N. Knox, King's Coll.; L. R. Lalwani, Bombay; B. A. Lamprell, King's Coll.; T. C. Pathology.—R. I. O'Farrell, Sheffield.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Monday, Nov. 14th, at 5 P.M., at the Medical Society, 11, Chandos-street, Cavendish-square, W., Mr. T. G. Stevens will give a lecture on the Treatment of Uterine Prolapse. On Wednesday, Nov. 16th, at 10.30 A.M., at the Victoria Park Hospital for Diseases of the Heart and Lungs, Dr. S. Roodhouse Gloyne will give a demonstration on the Pathology of Tuberculosis. The whole hospital will be open to post-graduates. On the same day, at 1 P.M., at the Royal London Ophthalmic Hospital, City-road, a demonstration will be given by Mr. Neame; and on Nov. 17th, at 2 P.M., at the London Temperance Hospital, Hampstead-road, Mr. Herbert J. Paterson will give a clinical demonstration in Surgery. The lecture and demonstrations are open to members of the medical profession without fee. From Nov. 14th to Dec. 3rd a course in surgery and gynæcology will be held at the Royal Waterloo Hospital, occupying the mornings and some afternoons. From Nov. 14th to 26th, in the afternoons, there will be a clinical course at St. Peter's Hospital, including a series of formal lectures on Diseases of the Urinary Tract. On Monday, Nov. 21st, to Dec. 17th, at 5 P.M., a series of lecture-demonstrations will be given at the West End Hospital for Nervous Diseases; and from Nov. 28th to Dec. 3rd there will be a course in Proctology at St. Mark's Hospital. Every afternoon from Dec. 5th to 17th a course of lectures and demonstrations will be given at the Infants Hospital, and during the afternoons of the same week a course will be given at the Blackfriars Hospital for Diseases of the Skin. A course will begin on Jan. 9th at the Prince of Wales's Hospital in medicine, surgery and the specialties, and on the same date a course on Diseases of Children will open at the Children's Clinic. Later, these will be followed by courses at the National Hospital for Diseases of the Heart, and at the Bethlem Hospital. Information, syllabuses, tickets, and specimen copies of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

ROYAL SOCIETY.—The officers of the society have been recommended for re-election at the anniversary meeting on Nov. 30th. They include Dr. H. H. Dale as one of the secretaries. Among the Fellows recommended for election or re-election to the Council are Dr. E. D. Adrian, Sir Hugh Anderson, Sir Archibald Garrod, Prof. J. C. G. Ledingham, and Prof. G. Elliot Smith. Mr. Stanley Baldwin, the Prime Minister, has been elected a Fellow of the Society under Statute XII.

ABERDEEN UNIVERSITY CLUB, LONDON.—The seventy-eighth half-yearly dinner will be held at the Piccadilly Hotel, at 7.30 P.M., on Nov. 24th. The secretary's address is 9, Addison-gardens, W. 14.

Dr. George Nicol Henry, divisional surgeon to the L Division (Lambeth), Metropolitan Police, has retired after 36 years' service with the force.

Dr. Graham Little, M.P., has been elected an honorary member of the Royal Academy of Medicine of Rome and a Fellow of the Royal Society of Physicians of Budapest.

Colonel R. A. Needham, of the Indian Medical Service, has been appointed as delegate of India at the session of the Office International d'Hygiène Publique, to be held in Paris this month.

HARVEIAN SOCIETY.—A meeting of this society will be held on Thursday, Nov. 17th, at 8.30 P.M., at the Paddington Town Hall. A discussion on the Ætiology and Treatment of Anterior Poliomyelitis will be opened by Dr. S. A. Kinnier Wilson, followed by Dr. James Collier.

TUBERCULOSIS SOCIETY.—A meeting of this society will be held on Friday, Nov. 18th, at 8 P.M., at the house of the Royal Society of Medicine, 1, Wimpole-street, W. Dr. G. T. Hebert will read a paper on the Treatment of Tuberculous Empyema by Replacement.

ROYAL MICROSCOPICAL SOCIETY.—A meeting will be held at 20, Hanover-square, London, W., on Wednesday Nov. 16th, at 7.30 P.M., when the President, Dr. J. A. Murray, F.R.S., will read a paper on Methods for the Demonstration of Bacteria in Frozen Sections, and other papers will be contributed.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A general meeting of this society will be held at 1, Upper Montague-street, Russell-square, London, W.C., on Friday, Nov. 18th, at 5 P.M. Dr. J. J. Buchan, Sir Oscar Warburg, and Lieut.-Col. F. E. Fremantle, F.R.C.P., will speak on Health Aspects of the Factories Bill.

BRITISH MOSQUITO CONTROL INSTITUTE.—Arrangements have been made by this institute for providing a two-day instructional course in laboratory and field work, for the convenience of persons going abroad who have no time or no desire to acquire more than an elementary knowledge of the principles and practice of mosquito control. Courses are to be held every month, the first to begin on Tuesday, Dec. 6th, and will be given at the institute, Hayling Island, Hampshire. Arrangements have been made for providing an additional day's instruction for those wishing to obtain more detailed information.

DONATIONS AND BEQUESTS.—Mr. H. Clifford Turner has given £750 towards the £3000 required to complete the cost of the building of the new wing of St. Mark's Hospital, City-road, E.C.—Mrs. Agnes Mary Ellis, of Ashby-road, Burton-on-Trent, left £300 each to Burton-on-Trent Infirmary, Burton-on-Trent Nursing Institution, and Dr. Barnardo's Homes.—Mr. James Hulse Humphryes, Bickley, Kent, left £4000 to his wife for distribution between the West Bromwich District Hospital, the Royal Gwent Hospital, Newport (Mon.), St. George's Hospital, Bombay, and the Presidency General Hospital, Calcutta, as she may see fit.—Lady Malcolm, of Portallach and Park-lane, W., left £50,000 for charities, including £2000 to St. Dunstan's Hostel for the Blind, for a bed to be named after her, and £2000 for the Hospital for Permanent Invalid Soldiers, Richmond; £1000 each to the Hospital for Sick Children, Glasgow, Evelina Hospital for Children, Southwark Bridge-road, Dr. Barnardo's Homes, and several other charitable institutions.—Lord Iveagh left £60,000 to the King Edward VII Hospital Fund for London.—Mr. Noel Edward Kinnell, Emsworth, Hants, left £1000 to the Emsworth Victoria Cottage Hospital.—Mr. Hugh Mitchell, of Sunderland, has given £1000 to the Royal Infirmary there.—Mrs. Margaret Elizabeth Willans Cullen, of Oxton, Birkenhead, besides other bequests, left £500 each to the Edinburgh Medical Mission and the Birkenhead and Wirral Children's Hospital, and £200 each to the Birkenhead Borough Hospital and the Birkenhead Maternity Hospital.—The Dunfermline and West Fife Hospital extension fund has received a donation of £2000 from Mrs. Andrew Carnegie.

UNIVERSITY OF LIVERPOOL.—Dr. Tudor Jenky Jones has been appointed lecturer in the department anatomy.

UNIVERSITY OF BRISTOL.—The Long Fox Memori lecture will be delivered by Dr. Henry Devine, at 8.15 P. on Tuesday, Nov. 29th, in the Physiological Lecture Theat of the University. His subject will be the Reality Delusions.

MEDICAL EXAMINATION OF EMIGRANTS.—T Government of the Dominion of Canada propose to establi a medical service in Europe for the free examination European emigrants wishing to proceed to Canada.

ANTI-MOSQUITO CAMPAIGN IN SOUTH AFRICA.—T Durban Town Council has invited Dr. A. J. Orenstein, Johannesburg, to visit Durban and consult with the pub health department in regard to anti-mosquito measures that town.

ROYAL WATERLOO HOSPITAL.—Last week the Lo Mayor of London opened an extension of this hospital a a new nurses' home. The work, which includes an in-patie operating theatre, private wards, an enlarged out-patien department, a massage department, and a waiting-hall, l cost £54,000, of which £8000 has yet to be raised.

PAYING PATIENTS IN SURREY.—The Governors the Royal Surrey County Hospital at Guildford ha unanimously decided that every in-patient, while s presenting a letter of recommendation, shall be required pay 3s. a day towards the cost of maintenance, except wh circumstances justify whole or partial remission.

BIRKENHEAD HOSPITALS.—Mr. J. H. Clegg, retiring mayor of Birkenhead, has during his year of of collected a fund of £15,000 in aid of the hospitals of town. Of this sum £12,000 will be allocated to the Gen Hospital, which has a debt of £6,000, and requires £7 for the reconstruction of the out-patients' department.

PRESENTATION TO SIR BERKELEY MOYNIHAN.— connexion with his retirement from the staff of the Le Royal Infirmary, a fund has been raised to present Berkeley Moynihan, P.R.C.S. Eng., with his portrait, the presentation was made by the Lord Mayor of Leeds Nov. 7th. The portrait is three-quarters life-size and is work of Mr. Richard Jack, R.A.

WORTHING HOSPITAL.—A good response has b made to the appeal which was launched in 1925 for the s of £25,000 for purposes of extension, and on Nov. two new men's wards were opened, with 15 beds on the gro floor and 11 on the first floor. The sum of £14,000 ha far been raised, but although the district served by hospital includes a population of between 40,000 and 50,0 the contributions have come from only 408 subscrib The institution will celebrate its centenary in August, 19

MEDICO-LEGAL SOCIETY.—A meeting will be h at 11, Chandos-street, Cavendish-square, W., on Thurs Nov. 24th, at 8.30 P.M., when Captain Norman Parkes read a paper on a Case of Pathological Drunkenness Defence of Insanity at a Murder Trial. A discussion follow.—The annual dinner of the society will be held the Holborn Restaurant on Friday, Dec. 9th, at 7 7.15 P.M., the President, Sir William Willcox, in the ch

THE SOCIETY OF M.R.C.S.'s ENG.—At the ann general meeting of Fellows and Members to be held the College on Thursday, Nov. 17th, the following res tion will be moved by Dr. E. E. Ware, President of Society:—

"That this 39th annual meeting of Fellows and Mem again affirms the desirability of admitting Members to d representation upon the Council of the College, and de to place on record its regret that the Council, in taking a p vote of its Fellows on this question, should have is simultaneously a statement of so biased and partisan a na and have omitted to elicit at the same time the views of Members."

This resolution will be seconded by Mr. Lawson Dick supported by Dr. Stella Churchill.

INTERNATIONAL CONGRESS OF OTO-LARYNGOLO As we have already announced this congress will be hel Copenhagen next year from July 30th to August 1st. assist those attending it from this country a British mittee has been formed with Sir James Dundas-Gran President, Sir StClair Thomson as Chairman, and Mr. L Colledge, Mr. J. S. Fraser, and Mr. Watkyn-Thoma hon. secretaries. Mr. Sydney Scott is acting as treasurer, the subscription of 5s. may be sent to him at 130, Ha street, W. 1. In return members of the committee wi kept informed of all arrangements, with particular travelling to Denmark and the stay in Copenhagen. committee is open to all members of the profession.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Reassembly of Parliament.

PARLIAMENT reassembled on Tuesday, Nov. 8th, after ne summer recess. A heavy programme of legislation left ver from the summer session has to be completed before the rorogation, which is expected to take place a few days efore Christmas. Among the measures which the Govern- ient hope to pass are the Mental Deficiency Bill and the ursing Homes Registration Bill.

HOUSE OF COMMONS.

TUESDAY, NOV. 8TH.

Medical Men and Professional Secrecy.

Dr. VERNON DAVIES asked the Minister of Health what ecision, if any, he had come to with regard to the necessity allowing medical men to preserve professional secrecy in e Law Courts with regard to certain diseases.—Sir INGSLEY WOOD (Parliamentary Secretary to the Ministry Health) replied: This question is still under consideration.

Slum Clearances.

Mr. HERBERT WILLIAMS asked the Minister of Health at progress had been made so far this year with the licy of slum clearances.—Sir KINGSLEY WOOD replied: 4 schemes dealing with slum areas have been confirmed. ese schemes cover approximately 14,000 houses, of which 94 had been acquired by Oct. 1st, and 4363 demolished. nders for the erection of 7776 houses in satisfaction of the ousing obligations imposed by these schemes had been proved at that date and 5205 houses actually completed. ce Jan. 1st 11 schemes have been submitted by local thorities and 11 confirmed by my right hon. friend. It ll be appreciated that during the current year local authori- s have concentrated their energies on the building of as ge a number of houses as possible under their new building ogrammes, and my right hon. friend has every reason to ppose that an increasing number of them will now turn eir attention to the execution of slum clearance schemes hich they have already had under consideration for some ne past.

Industrial Training and Physical Disability.

Mr. LANSBURY asked the Minister of Labour how many n had passed through the residential training centres nnected with his department since the opening of those ntres up to Oct. 31st; how many were discharged as unfit training owing to physical or other disability; how many l obtained work on the land in Great Britain; how many l emigrated; and what number had obtained employment herwise than on the land.—Sir ARTHUR STEEL-MAITLAND plied: Up to the end of October 988 men had passed ough a course of training for employment on the land erseas, of whom 976 have been placed on farms in Australia Canada. 364 men received a general course of training for dustrial employment in this country, of whom 309 are own to have secured employment. In addition 63 men re been discharged as unfit to continue training on dical grounds.

Medical Adviser to Mines Department.

Ir. LUNN asked the Secretary for Mines if he could now ve the name of the new medical adviser to the Mines partment and his qualifications to enable him to deal h the various diseases peculiar to the mining industry.—Conel LANE-FOX replied: One of the candidates for the t has been selected, and the usual inquiries by the Civil Service Commission are proceeding.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Nov. 14th.—5 P.M., WAR. Paper: Major E. C. Lambkin, R.A.M.C.: Recent Investigations into the Treatment of Gonorrhœa.

TUESDAY.—5.30 P.M., GENERAL MEETING OF FELLOWS. Ballot for election to the Fellowship. 8.30 P.M., PATHOLOGY. Communications: Prof. J. McIntosh: The Histology of Some Virus Infections of the Central Nervous System. Prof. C. A. Pannett: Some Experiments on Tissue Survival. Dr. I. H. Maclean: The Mechanism of Experimental Leucocytosis. Demonstrations: Dr. J. M. Ross: (1) Bilateral Thrombosis of the Renal Vessels. (2) Ureteritis Hypertrophica Cystica. Dr. J. W. Orr: Sebaceous Glands in the Œsophagus.

WEDNESDAY.—7.30 P.M., ANNUAL DINNER OF THE SOCIETY, Hotel Victoria.

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) Cases: Dr. J. A. Drake: Schamberg's Disease. Other cases will be shown. 8.30 P.M., ELECTRO-THERAPEUTICS, MEDICINE, SURGERY, ORTHOPÆDICS. Special Discussion on Radiological Pitfalls. Openers: Dr. A. E. Barclay (Electro-Therapeutics), Dr. E. I. Spriggs (Medicine), Mr. Max Page (Surgery), Mr. H. A. T. Fairbank (Orthopædics); Dr. A. F. Hurst and Mr. A. C. Jordan will also speak.

FRIDAY.—8 P.M., OBSTETRICS. Short Communications: Mr. J. P. Hedley: A Case of Papilliferous Ovarian Cysts. Dr. J. S. Fairbairn and Mr. T. H. Sims: Pseudomyxoma Peritonei Associated with Ruptured Ovarian Cyst and Appendicular Disease. Paper: Mr. A. R. Walker: Diabetes Mellitus and Pregnancy.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Nov. 14th.—8 P.M., Clinical Evening.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THURSDAY, Nov. 17th.—8.15 P.M. (at the London School of Hygiene and Tropical Medicine, Endsleigh-gardens, Euston-road), Dr. Mary V. F. Beattie, Major H. C. Brown, Dr. P. A. Buxton, Dr. A. Castellani, Captain W. Dye, Dr. H. M. Hanschell, Colonel S. P. James, Colonel Clayton Lane, Dr. P. H. Manson-Bahr, Dr. N. A. Dyce Sharp, Drs. J. Gordon Thomson and A. Robertson, Dr. V. B. Wigglesworth, and Dr. C. M. Wenyon will give demonstrations.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY, Nov. 16th.—8 P.M., Prof. Leonard Hill: Overcrowding in Public Conveyances.

LONDON CLINICAL SOCIETY.

THURSDAY, Nov. 17th.—9 P.M. (at the London Temperance Hospital, Hampstead-road), Discussion on Dyspepsia (postponed from previous meeting). Openers: Dr. John Ryle and Mr. Herbert Paterson.

CHELSEA CLINICAL SOCIETY.

TUESDAY, Nov. 15th.—8.30 P.M. (at the Hotel Rembrandt, Thurloe-place, S.W.), Sir William H. Willcox and Dr. William Hunter will open a discussion on Focal Sepsis. The meeting will be preceded by dinner at 7.30 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

TUESDAY, Nov. 15th.—5 P.M., Dr. P. C. Varrier-Jones: Village Settlements for the Tuberculous (Mitchell Lecture).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

THURSDAY, Nov. 17th.—3 P.M., Annual Meeting of Fellows and Members.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Nov. 14th, to SATURDAY, Nov. 19th.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society 11, Chandos-street, Cavendish-square, W., on Mon., at 5 P.M., by Mr. T. G. Stevens: The Treatment of Uterine Prolapse. No fee.—HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E. Clinical demonstration on Wed., at 10.30 A.M., by Dr. S. Roodhouse Gloyne on the Pathology of Tuberculosis, in the Laboratory and Museum. The whole hospital will be open to post-graduates all day. No fee.—LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. Clinical demonstration on Thurs., at 2 P.M., by Mr. Herbert J. Paterson on Surgery. No fee.—ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C. Clinical demonstration on Wed., at 1 P.M., by Mr. Neame on Ophthalmology. No fee.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Post-graduate course in Medicine, Surgery, and Gynæcology occupying afternoons and some mornings, with lectures and clinical demonstrations, and operations.—ST. PETER'S HOSPITAL, Heprietta-street, Covent-garden, W.C. Post-graduate course in Urology, occupying every afternoon, with lectures and demonstrations and operations. Fee £5 5s. for two weeks' course.—NATIONAL HOSPITAL, Queen-square, W.C. Special post-graduate course in Neurology. Further information from the Secretary, Mayfair 2236.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Nov. 14th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

There will also be a special demonstration of medical cases at 2.30 P.M. on Monday, and of cases for X ray on Thursday, at 2 P.M., by Dr. J. Browning Alexander and Dr. A. C. Dixon respectively.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Nov. 15th.—5 P.M., Dr. G. B. Dowling: Mycotic Diseases.

THURSDAY.—5 P.M., Pathology Demonstration.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.

MONDAY, Nov. 14th.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Donald Armour: Operations. 2 P.M., Dr. Trevor Davies: Gynæcological Out-patients.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 2 P.M., Mr. Addison: Operations. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 4.30 P.M., Dr. Dowling: Preservation of a Youthful Skin (lecture).

THURSDAY.—11 A.M., Resident Assistant Surgeon: Ward Demonstrations. 3 P.M., Sir Henry Simson: Gynæcological Ward Visit. 4.30 P.M., Mr. Tyrrell Gray: Gastric and Duodenal Ulcer (lecture).

FRIDAY.—11 A.M., Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.

Daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M., In- and Out-patients, Operations, Special Departments.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Nov. 18th.—4 P.M., Mr. J. D. McLaggan: Otosclerosis.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.

TUESDAY, Nov. 15th.—4 P.M., Mr. L. G. Phillips: Clinical Demonstration of Gynæcological Cases.

ROYAL NORTHERN HOSPITAL, Holloway, N.: POST-GRADUATE COURSE.

TUESDAY, Nov. 15th.—3.15 P.M., Dr. E. G. B. Calvert: Recent Work on Exophthalmic Goitre and Allied Disorders with Cases.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Nov. 17th.—4 P.M., Mr. Twistington Higgins: Congenital Pyloric Stenosis.

ANCOATS HOSPITAL (Mill-street, Manchester) POST-GRADUATE LECTURES.

THURSDAY, Nov. 17th.—4.15 P.M. (tea at 3.45 P.M.), Dr. Kletz: Medical Treatment of Peptic Ulcer.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

FRIDAY, Nov. 18th.—3.30 P.M., Mr. Townrow: Differential Diagnosis of Facial Pain.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.

TUESDAY, Nov. 15th.—4 P.M., Dr. Edwin Matthew: The Clinical Significance of Hæmatemesis. Discussion to be opened by Prof. Patrick.

FRIDAY.—4 P.M., Case reading and discussion, in which all medical practitioners are invited to take part.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Nov. 15th.—4.15 P.M., Dr. A. H. Holmes: Diagnosis of Pulmonary Disease.

FRIDAY.—4.15 P.M., Mr. J. Spalding: Demonstration at the Schools, Old Trafford, showing Physical and Educational Development of the Deaf Child.

PEOPLE'S LEAGUE OF HEALTH.

THURSDAY, Nov. 17th.—6 P.M. (at 11, Chandos-street, Cavendish-square, W.), Prof. B. Collingwood: Digestive Organs and Lymphatic Glands.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Nov. 16th.—4 P.M., Dr. Stenhouse Williams: The Milk-supply; What Shall our Policy be?

Appointments.

LAING, J. N., M.B., Ch.B. Manch., has been appointed Assistant Deputy Coroner of Manchester.

RHODES, W. F., L.R.C.P. Lond., M.R.C.S., Government Pathologist at Cape Town.

Certifying Surgeons under the Factory and Workshop Acts: BLAIR, A., M.B., Ch.B. Glasg. (Breage District of Cornwall); CAMPBELL, D., M.B., Ch. B. Aberd. (Ellon District of Aberdeen).

Vacancies.

For further information refer to the advertisement columns.

Aberdeen University.—Assistant in Pathology. £250 12*s.*

Birmingham and Midland Ear and Throat Hospital.—Asst. Surg.

Brighton, New Sussex Hospital for Women and Children.—Hon. Asst. Surg. and Hon. Asst. Anæsthetist.

Bristol General Hospital.—Hon. Surg. Reg. Also Hon. Asst. P.

Cairo, Egypt, Girls' Schools under the Ministry of Education.—Asst. Med. Inspector. L.E.480.

Chelsea Hospital for Women, Arthur-street, S.W.—Jun. H.S. At rate of £100.

Chester, Wrenbury Hall Tuberculosis Training Colony.—H.P. £250.

Chesterfield and North Derbyshire Royal Hospital.—Res. Surg. O. £300.

City of London Hospital for Dis. of Heart and Lungs, Victoria Park, E.—Res. M.O. £250. Also H.P. At rate of £1

City of London Maternity Hospital, City-road, E.C.—Obstet. to In-patients. Also Asst. Obstet. S.

Dreadnought Hospital, Greenwich.—Med. Supt. £300.

Dublin, Irish Medical Association.—Representative. At rate £100 for six months.

Dublin, Sir Patrick Dun's Hospital.—Clinical Physician.

Dumfries, Crichton Royal.—Clin. Pathologist. £400.

Durham County and Sunderland Eye Infirmary.—Locum.

East London Hospital for Children and Dispensary for Wom Shadwell, E.—Phys. Also Asst. Phys.

Elizabeth Garrett Anderson Hospital, 144, Euston-road, N.W H.P. Obstet. Asst., 2 H.S.'s. Each at rate of £50. A Clin. Assts.

Evelina Hospital for Children, Southwark, S.E.—H.S. £120.

Golden-square Throat, Nose and Ear Hospital.—H.S. £100.

Hospital for Sick Children, Great Ormond-street, W.C.—A Pathologist. £400. H.P. and H.S. At rate of £50. A Med. Reg. £250.

Infants Hospital, Vincent-square, Westminster.—Med. R £120. Also Asst. Surg.

Inverness, Northern Infirmary.—Jun. Med. Resident. £100.

London Jewish Hospital, Stepney Green, E.—Res. M.O. A Jun. Res. M.O. At rate of £150 and £100 respectively.

Malayan Medical Service.—Medical Inspectors of Schools. £7

Manchester, Ancoats Hospital.—Res. Med. O. At rate of £1

Manchester, St. Mary's Hospitals.—Hon. Consulting Surg.

Middlesex Hospital, W.—Res. M.O. £400. Also Asst. Ra logist. £150.

Middlesex Hospital Medical School.—Two Surgical and Medical Registrar. Each £300.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Phys.

New Zealand Research Laboratories.—Dairy Research Bacte logist. £850.

Norwich, Norfolk and Norwich Hospital.—Cas. O. and H £120.

Poplar Hospital for Accidents, East India Dock-road, E.—Sec Res. O. £175.

Prince of Wales's General Hospital, N.—Hon. Clin. Assts.

Royal Free Hospital, Gray's Inn-road, W.C.—Two Assts. M.O. in charge of V.D. Dept. Each £500. Surg. £200. Med. Reg. and Gynæcol. Reg. Each £100. A H.S.'s., H.P., Second H.P., and Obstet. Asst.

Royal Northern Hospital, Holloway, N.—Asst. Radiologist. £1 Out-patient M.O. At rate of £125. Also H.S. At r of £70. Also Ophth. S.

Royal Waterloo Hospital for Children and Women, Waterloo-rd S.E.—H.P. At rate of £100. Also Anæsthetist. rate of £25.

St. Bartholomew's Medical College.—Demonstratorship Physiology.

Salisbury General Infirmary.—H.S. £150.

Shrewsbury, Royal Salop Infirmary.—Sec. Supt. £600.

Sierra Leone, School Laboratory, Freetown.—Two Research As Each £600.

Southampton, Royal South Hants and Southampton Hospita Cas. O. £120.

Staffordshire Mental Hospital, Cheddleton, Leek.—Jun. A M.O. £350.

Surrey County Council.—Asst. M.O.'s. Each £600.

Swansea Hospital.—H.S. to Ophth. and Aural Depts. £150–£

Tipton Urban District Council.—M.O.H. £800.

Walthamstow, Wanstead, and Leyton Children's and Gen Hospital.—Hon. Asst. S. to Throat, Nose and Ear Dept.

Warwick County Mental Hospital, Hatton.—Asst. M.O. £30

West London Hospital, Hammersmith, W.—H.P., H.S., Asst., Cas. O., and Aural and Ophth. H.S. Each at of £100.

The Chief Inspector of Factories announces the follow vacant appointments for Certifying Factory Surgeons Southampton (Hampshire) and Wolston (Warwickshire

The Secretary of State for the Home Department gives no of a vacancy for a Medical Referee under the Workm Compensation Act, 1925, for the Districts of the Gr Thurrock and Southend County Courts. Applications sho reach the Private Secretary, Home Office, not later t Nov. 26th.

Births, Marriages, and Death

BIRTHS.

ANNING.—On Nov. 2nd, at Harrogate, the wife of Dr. C. C Anning, of a daughter.

BEAUCHAMP.—On Nov. 6th, at Church-hill, E., the wife of W Beauchamp, L.D.S. Eng., of a daughter.

DE CAUX.—On Oct. 29th, at Weymouth-street, W., the wife Dr. Francis Percival de Caux, of a son.

MARRIAGES.

KUNHARDT—EDWARDS.—On Oct. 29th, at All Saints' Chur Ealing, by the Rev. C. J. Sharp, Lieut.-Colonel J. C. Kunhardt, I.M.S. (retd.), to Marian Campbell, young daughter of the late David Edwards, Hatton, Ceylon, Mrs. Edwards, Ingl s-road, Ealing.

DEATHS.

MORRISON.—On Oct. 2nd, in the Soldiers' Home Annexe, Angeles, California, Malcolm McLean Morrison, M Ch.B. Edin.

PETTERSSON.—On Nov. 4th, following an operation, Dr. Her Pettersson, of Wetherby-place, S.W.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

ANIMAL EXPERIMENTATION AND KNOWLEDGE.*

BY GRACE BRISCOE, M.B., B.S. LOND.

THE probability that the Dogs Protection Bill will be roduced another year, and the possibility of fresh legis-ion, prompted the executive of the Medical Women's deration to call for discussion and consideration of the ole question of animal experimentation. As the anti-risection agitation is largely run and financed by women, e opinion of this body of scientifically trained women comes of peculiar importance. The fight that is coming l be largely about dogs, but the whole principle of animal perimentation is at stake. The petition in support of the l was signed by over a million people, but many of these natures must have been secured under a misapprehension, the petition contained this false statement: "The dog s of late years been specially selected by vivisectors for ensive and peculiarly revolting and painful experimenta-n, and also for demonstrations of a prolonged and agonising ure before classes of students." The Under Secretary of te for the Home Office said in the House of Commons, in swer to this statement: "No such experiments would be mitted, and there is no evidence whatever that any have en place. In the case of experiments before students, y are all required to be performed under anæsthetics l the animal must be killed before it recovers consciousness." Nevertheless the false statement must have caused dless mental suffering to many animal lovers; those o were distressed should remember that disease is the in cause of suffering in the animal world, and the only y to alleviate it is to conquer disease by the spread of owledge.

The Fundamental Principle.

f it is wrong to use dogs in the search after knowledge it qually wrong to use any other of the higher animals. If s permissible to experiment on animals for the sake of fering humanity, then we must not shrink from applying t principle to the most domesticated of all animals, the , provided that there is a real necessity for its use. dical women must face this issue, as they have, perforce, use the results gained from animal experimentation in ryday practice. Can they, in all fairness, disapprove of h experimentation and, at the same time, make use of eficial knowledge gained therefrom?

o one will claim that the case for animal experimentation be granted without careful consideration. Everyone o holds a licence has to ask himself or herself if experi-ntation is morally justifiable. I have every respect for vegetarian who refrains from animal food on the ground t it is wrong to take animal life, but to carry out that nciple logically and universally would lead humanity into impossible position. The imagination boggles at the ught of a world existing on vegetable food only, without without wool, without leather. It seems part of the eral design of nature that higher animals should make of lower animals for food. The use of animal flesh for l is treated as part of the settled order of things, and e is no indication that such a proceeding is inconsistent h true humanity.

The Pronouncements of Royal Commissions.

We may take it for granted that, in general, mankind ms and exercises the power of life and death over nals, both for food and clothing. Are we justified in ming that power for the spread of knowledge? If we show that animal experimentation, performed under t careful safeguards against unnecessary suffering, has ught about a tremendous increase of knowledge and thus led directly to an astonishing alleviation of disease and ering, both in men and animals, then we can claim, and m boldly, the right to continue investigation without handicap of unnecessary limitations.

he subject has been repeatedly investigated by Royal missions. The verdict of the Royal Commission of 1912 thus: "Experiments upon animals, adequately safe-rded by law, faithfully administered, are morally ifiable and should not be prohibited by legislation." In 7 the chairman of another Royal Commission, Lord lton, a distinguished lawyer as well as a scientist, : "No man who knows anything of science has any bt whatever that the right way to advance knowledge is experiment. . . . When we are reduced to observation, the science crawls. When, and in proportion as you use experiment, the science advances rapidly. . . . As soon as you can bring experiment to bear upon a subject, you are free, but as long as you can merely observe, your progress is very slow. The reason is that experiment is like cross-examination, you can put the question you want, and nature always answers it."

The Safeguards.

It is right that such experiments should only be carried out under stringent safeguards, and they are most strictly controlled. Only those who hold a licence direct from the Home Office may perform an experiment on a living animal, and the experiment must be carried out in a specified place. Such experiments can only be performed in licensed laboratories, and the laboratories must always be open to inspection by the official inspectors. A strict record has to be kept of all experiments, and the record book is always open to inspection. All published articles describing experimental work have to be submitted to the Home Office. No one is granted a licence unless they are recommended as suitable by persons eminent in science or medicine. These safeguards make it almost impossible for unnecessary experiments to be performed by irresponsible persons.

There are three main classes of experiments. The first class includes feeding experiments and all inoculations and injections, which are practically painless and can be performed without an anæsthetic. The second class includes all severe operations, which must be performed under complete anæsthesia, and the animal must be killed before it recovers from the anæsthetic. The third class includes those experiments in which the animals are allowed to recover, although the initial operations are all done under an anæsthetic.

The first class covers the vast majority of all experiments. The Home Office report, published in July of this year, says: "In no instance has a certificate dispensing with the use of anæsthetics been allowed for an experiment involving a serious operation." Many of these experiments are performed on behalf of official bodies, with a view to the preservation of the public health. The Ministry of Health and the Ministry of Agriculture and Fisheries maintain laboratories which are registered for the performance of experiments having for their object the detection, prevention, and study of diseases of man and animals. Of the total number of experiments, 23 per cent. were carried out for Government departments and other public health authorities, and 46 per cent. of all experiments were for the preparation and testing of antitoxic sera and vaccines, and for the testing and standardising of drugs. These experiments on the whole involve no greater surgical procedure than an injection of strychnine or morphia, or a withdrawal of blood for diagnostic purposes. If a patient has an attack of pleurisy it is vitally important, for the sake of after-treatment, to know if the infection is tuberculous; the decisive test on a guinea-pig would be carried out under this class of licence. The practice of medicine would be greatly hampered if this kind of experiment were not allowed.

The second class of experiments is that in which the animal is not allowed to recover from the anæsthetic, and this covers 1·9 per cent. of the total number of experiments. In these experiments, as in an ordinary surgical operation, no pain is involved.

In the third class of experiments, where animals are allowed to recover, there are special safeguards. They may not be done under licence alone, but the experimenter must be provided with a special certificate, and due cause must be shown why such certificate should be granted. This class includes 2·7 per cent. of the total number, and of these only 5 per cent.—i.e., only 0·14 per cent. of all experiments—are on cats and dogs.

The initial operations are performed under anæsthetics and have to be carried out antiseptically, so that the healing of wounds shall, as far as possible, take place without pain. If antisepsis fails and suppuration occurs, the animal has to be killed. The Home Office report points out that "after the healing of the wounds the animals are not necessarily, or even generally, in pain, since experiments involving the removal of important organs, including portions of the brain, may be performed without giving rise to pain after the recovery from the operation; and after the section of a part of the nervous system the resulting degenerative changes are painless."

It must be remembered that there is little evidence that animals feel pain to the same degree as human beings. Animals do not go off their sleep or food after o eration in the way that humans do, but will run about the theatre and begin feeding directly they have recovered consciousness.

The Contribution of Animal Experiments to Modern Medicine.

Harvey was the originator of the modern method of experiment, as opposed to observation, and by means of his

* An address delivered to the London Association of the dical Women's Federation on Oct. 25th, 1927.

experiments on animals, mostly dogs, he laid the foundations of our present knowledge of the heart and the circulation. This discovery was made by experiment, not by observation. Up to this time it was commonly believed, as the fruit of centuries of observation, that the arteries contained air. Another great landmark was the discovery of chloroform; in this case the experimental animal was man, and the later details were worked out on dogs. But if these particular investigations were first made on volunteer man, that was still experimentation; indeed, in the true sense of the term, any surgical operation is "a vivisection." Later came the revolutionary discoveries of Lister, the dawn of antisepsis, and as a direct result the growth of modern surgery. Lister, giving evidence before the Royal Commission on Vivisection in 1875, said: "They (animal experiments) had the effect of giving me a kind of pathological information, without which I believe I could not by possibility have made my way in the subject of antiseptics. I have often felt that without the basis which I derived from experiments on the lower animals, I should never have been able to thread my way through the very perplexing, and apparently contradictory, facts which I met in the first instance." When Queen Victoria asked him to pronounce in condemnation of vivisection, he wrote in reply a long letter justifying the practice and proclaiming its necessity. In the course of this letter he said: "I have myself often performed experiments upon the lower animals, and if I have been privileged in my professional career to do anything for the good of my fellow men, more is to be attributed to these experiments than to any other work in which I have been engaged."

Much of Pasteur's work was done on crystals, yeasts, and moulds, but one of his most important researches was his investigation of rabies and his method of attacking that scourge. That work was only made possible by experiments on rabbits and dogs, and it has been of even more benefit to animals than to human beings.

When we remember that not only antisepsis, but the germ theory of disease, sprang from the combined work of Pasteur and Lister, we realise that the whole of modern surgery, and a considerable part of modern medicine, are directly derived from the knowledge these men gained from experimentation.

Diphtheria antitoxin was discovered by experiments on animals. The Metropolitan Asylums Board published a chart showing the result of using antitoxin in their hospitals. It came into use about November, 1894. The chart referred only to cases of laryngeal diphtheria and thus excluded all the mild cases. In 16 years the mortality from this class of severe case was reduced from 62 per cent. to 11·7 per cent. Before 1894 the average mortality among diphtheria cases, taking all cases together, whether slight or severe, was 30·4 per cent.; this was reduced to 8·3 per cent.

The preparation of calf lymph involves the use of animals. In 1924 there was a sudden outbreak of virulent small-pox in Ontario, Canada. The total number of cases was 67 and the number of deaths 32. The total population of the district was about 70,000 persons, and the Board of Health decided to vaccinate everyone immediately. No compulsion was used, but everybody, including the antivaccinationists, complied. Within six days 95 per cent. of the population had been vaccinated. As a result the epidemic was suddenly brought to an end. The statistics showed (for a detailed account see a publication of the Research Defence Society) that no person who had ever been vaccinated successfully at any time in his or her life died of small-pox; yet of the persons who had never been vaccinated successfully and who developed the disease 71 per cent. died. No one who had been vaccinated successfully within the last 12 years took small-pox at all.

Alleviation of Suffering due to Experiments on Dogs.

Dogs are not used for experiment if some other animal is equally suitable; they are expensive, and there is a natural sentiment against using animals who show such powers of friendship and companionship with mankind. The type of animal to be used for a particular experiment must be left to the judgment of the individual researcher; no one else is in a position to make the decision.

The technique of original and difficult surgical operations, like those on the gall-bladder and bile-ducts, was worked out on dogs, with the result that patients were spared a period of experimental operation, during which the mortality would certainly have been higher than was actually the case.

In some cases an incurable condition of myxœdema followed early operations for removal of the thyroid in goitrous patients. If more had been learnt of the functions of the thyroid by preliminary experiments on animals, those disastrous results would have been avoided. Consider the different degrees of suffering involved in the two cases. The dog experiences none of the preliminary agony of anticipation, which must be intensified when a patient knows that the operation he is about to undergo is, more or less, of an experimental nature. The animal is anæsthetised without any pain or distress, and in a large numb of cases is killed before it can come round again. So t total pain inflicted is infinitely less than in the case of t human, who has to bear the extreme discomfort of recover Anyone who has been through a serious operation kno that the worst part is the struggle back to consciousnes From the point of view of the infliction of least pain t humane way is to carry out preliminary trial operations suitable animals, and, as a rule, the most suitable are lar dogs.

The size of the dog makes it especially suitable f investigating problems of the circulation; other lar domestic animals cannot be kept conveniently in laborato quarters. Moreover, the dog's circulation more near resembles that of man than does the circulation of any oth domestic animal. The recent advances in our knowled of the mechanism of the heart-beat, of the nature of auricul fibrillation, and of the variations of the pulse, have be grounded on, or made possible by, experiments on do The new cardiac knowledge has relieved much needl mental suffering, where patients had been unnecessar condemned, through a misunderstanding of physical sig to lead inactive lives amid apprehensions of sudden dea

Again, the indirect method of measuring the blood pressu devised by Riva Rocci as the direct result of experiments dogs, is one of the most valuable weapons in the diagnos outfit.

The action of drugs and anæsthetics is very similar dogs and man. If the testing of new drugs is not to be carri out on dogs, then the alternative must be the patie The chemical constituents which cause the activity pituitrin have not been isolated, and it is therefore necessa to use physiological methods of assay.

In the nervous system the dog is nearer man than a other animal, except the monkey. When cerebral localisat was being worked out, it was found that there were fe centres which were represented both in man and in the which had not been discovered in the cat. These ea experiments on the dog led to a great increase in our kno ledge of the nervous system; nowadays, however, dogs ha been superseded by monkeys.

Dogs can thrive on a mixed diet very similar to ma and lessons learned from experimental diets can theref be applied directly to man. That rickets is a dise essentially due to a faulty diet is a piece of knowledge wh has been derived from puppies, and the knowledge causation indicates the cure. These painless experiments dogs, therefore, have not only led to a great decrease malnutrition among our children, but they have also tau us that early decay of the teeth and faulty enamel are to deficiencies in the diet. All these painless diet experime have to be carried out under licence, and make a la addition to the total number of experiments carried annually in this country.

The analysis of the chemical processes taking place the separate organs of the body during the digestion food was worked out by experiments on dogs, and analysis has led to a great improvement in the diagn and treatment of disorders of the stomach and intesti The only other possible animal for these experiments the cat, but the small size of its organs and the differe in its food and habits made it an unsuitable subject.

The work now being carried out by Pavlov on the fun mental instinctive reflexes in dogs is throwing a new l on the functions of the cortex, and will be of great valu psychology. Both in man and animals the aggregate reflexes constitute the foundation of our nervous activi Pavlov has constructed a special hospital for his anim and a full surgical routine is followed. He emphasises necessity for these precautions, without which reliable cannot be obtained.

Before the discovery of insulin there was no drug kn which could control diabetes, but since then many valu lives have been saved, sufferers returned to full work, much distress alleviated. All the experiments leadin this discovery were performed on dogs and, as far as know, could not have been performed on any other ani In this investigation the animals had to be kept alive a operation. The fact that dogs can be handled and band more easily than other animals is an important considera in selecting the experimental subject.

The method of resuscitation from drowning, associ with the name of Schäfer, was worked out on dogs, and been the means of saving many lives.

It must not be forgotten that animals themselves h benefited almost as much as man from the increas knowledge. Those who hold that their love of dogs bl them to the sufferings of humanity do not seem to re that experiment is going to reduce the sum total of an suffering. In addition to rabies, glanders and ant have been largely checked by the increase in knowledge w has resulted from animal experiments. The cure for m nant jaundice in dogs was discovered by experiment

gs, and has enabled dog lovers to keep animals in those rts of Africa where it was formerly impossible, owing to e high mortality (80 per cent.) from this disease. Again, erations can now be performed on valuable dogs, as we ow how to administer an anæsthetic with safety. There a crying need for more knowledge on the subject of temper, and those who are responsible for the *Field* temper Fund are wholly opposed to the Dogs Protection ll, as they hold that its passage would interfere with work ich is designed to relieve suffering amongst dogs. Veter- ry science is reduced to the wholesale slaughter of animals order to check foot-and-mouth disease; in a recent out- ak in the United States animals and other property to the value of $5,000,000 had to be destroyed, and the s in this country is commensurate. We cannot control se animal diseases until we know more about them.

There are many human problems still awaiting solution. ere is the problem of cancer, which kills about 50,000 people this country every year; tuberculosis is still a fatal ease; we know very little about encephalitis lethargica, her its cause or treatment; the pathology of influenza and group of kindred infective diseases is not fully known. en the vexed question of diet has not been finally settled. restigations must be crippled and hampered if dogs are luded from experiment.

Where Cruelty to Animals may be Found To-day.

There is great injustice in the charges of cruelty which are ught against investigators. Unscrupulous people will te experiments which were done many years ago, before esthetics were discovered, as being carried out now, or te those done abroad where control is not so strict as this country. The vast majority of experiments are nless, and the total amount of suffering is small compared h that caused by some forms of sport, or by a procedure h as castration. The operation of castration is allowed hout an anæsthetic. In the larger farm animals the end ieved by this operation (very painful if performed by kilful or uncleanly hands) is merely to make meat more der for human consumption. The owners of some ieties of dogs cut off their puppies' tails without an esthetic. No experimenter would be allowed to cut off tails of lambs or puppies, or to castrate an animal without anæsthetic. The societies which aim at preventing cruelty animals might well concern themselves more with these cedures, unsafeguarded by law and carried out for mmercial purposes, rather than attempt to hamper ntific research, which is legally authorised and supervised Government inspectors.

Without animal experiments in the past little of the dern equipment of the doctor would be left save the thoscope, and the use of that unaided has led to many apprehensions. It is difficult to think of any outstanding ance in modern medicine which has not been founded on nal experiment.

In the memorandum recently presented by the Medical Research Council to the Privy Council it is pointed out that 5,000 stray dogs are annually destroyed in London alone, because their owners are too callous or too poor to look after them properly. Under the Dogs Act of 1906 these dogs, when seized by the police, have to be destroyed if they are not claimed within seven days, and none can be used for the purpose of experimentation. Now if some of these animals were used for the purpose of painless experiment, no more would happen to them than if they had been sent to the ordinary lethal chamber, except that the anæsthetic would probably be administered in a more skilful manner in a laboratory. It would be necessary to provide for an adequate period before taking the animal's life, so that dog owners would have ample opportunity to recover lost or stolen dogs. The Council urged that the section of the Act relating to the destruction of stray dogs should be repealed. Such a repeal would remove from investigators the danger of using valuable or stolen dogs, a risk from which they cannot be entirely free under the present circumstances. Such a repeal would also do away with the incentive to dog-stealing and rectify the present anomalous position in the supply of dogs. To breed dogs especially for the purpose of experiment would be extremely expensive, and if there are stray unwanted dogs which have to be destroyed anyway, it would seem a superfluous proceeding to breed more. If, as I have suggested, legislation is proposed to permit the use of stray dogs, there is certain to be an acute controversy. Many general practitioners will be questioned by patients as to the rights and wrongs of the subject. Some patients will hold convinced and extreme views, and no amount of logic and argument will shake them. There will be many others who, though reluctant on sentimental grounds to acquiesce in the use of dogs, are yet unwilling to allow their sentimental emotion to override their sense of logic and judgment. These latter will demand a reasoned statement of the grounds on which science builds its claim to use animal life in the pursuit of knowledge. It is well to be equipped with a knowledge of results that have been attained in the past and a realisation of the many problems still awaiting solution, and to pass them on to such patients. In this way an enlightened public opinion on the subject will be built up.

The work of original investigation is very arduous and the material rewards are poor. It is only fair that the people who are best placed for seeing the benefits derived from its results should give moral support to those engaged in research, and protect them from abusive attack.

A DEBATE ON HUMANE SLAUGHTERING.

AT a debate held on Nov. 4th at the Birkbeck College under the auspices of the University of London Animal Welfare Society, discussion largely centred round the preliminary stunning of animals by means of mechanically operated instruments. The older methods of killing animals were held by several speakers to be cruel. The use of the pole-axe, with its broad axe end and more rounded thimble end, was warmly attacked and defended. The advocates of mechanically operated instruments made much of the ease with which slaughterers could become proficient in their use by practice on heads of dead animals; they took up the position that experience in the older methods has to be acquired by practice on living animals; sheep, owing to their docility were the unfortunate animals on which the older methods, other than the use of the pole-axe, were learnt. Mr. A. C. Knight, a past president of the London Meat Traders' Association, stated that slaughtermen acquired skill in the use of the pole-axe by learning to cut the horns of cattle. Several references were made to the City of London investigation, in which it was ascertained that in the killing of 100 bulls 249 blows with the pole-axe were struck, 100 steer were struck 123 times, 100 cows 127 times, and 100 pigs 155 times. Mr. Knight stated that his slaughterman had in nine months killed 251 bullocks with 253 blows.

Mr. A. C. Dewbury, manager of the Humane Slaughtering Department, R.S.P.C.A., referred to the squeal pigs gave when throats were cut as being different in character to their ordinary squeals and consequently as being an indication of pain. The claim that the severance of the large vessels of the neck by sticking results in immediate unconsciousness ("Dr. Leonard Hill says so") was disputed on evidence of a persistent corneal reflex. Other arguments not mentioned were the continuance of supply of blood to the brain by the vertebral arteries; Dr. Pfister, director of the Zurich abattoir, found that when animals have been stunned before being killed their meninges are normal, whereas in animals killed without previous stunning the meninges are intensely congested, an observation from which the deduction is made that suffering has occurred in the unstunned animals. The common practice of hoisting large (bacon) pigs by one leg before killing was condemned as cruel. Mr. Knight, in the course of the debate, stated that the use of the "maul"—a long hammer to stun pigs—was cruel; we have outside confirmation of frequent failure to stun the animal with one blow. The same speaker also condemned the tying of the legs of sheep together prior to sticking. The R.S.P.C.A. superintendent of slaughtering argued that all pig-stickers were not expert; an expert pig-sticker can command high wages, and all pig-stickers were not paid high wages; he thought that some of the pig-stickers never became expert.

Evidently "humane killing" has obtained many followers in this country; no less than 255 local authorities have adopted the by-law requiring this method of slaughtering, not, however, in every case for all species of animals—e.g., in Reading pigs need not be so killed. The Ministry of Agriculture recommends it for killing animals infected with foot-and-mouth epidemics. The London County Council had made an inquiry lasting nine months before adopting the by-law, obtaining information from Holland, Denmark, Norway, Sweden, and Germany. Mr. Dewbury made out a good case for the captive bolt. Although more than one speaker, including a slaughterman, stated that misfires often took place, it was evident that in the hands of a careful person these were rare. Captain C. W. Hume pointed out that it had been found that 1259 shots only were necessary to kill 1255 animals. Mr. Knight made the criticism that most of these animals were small, and that only a comparatively few bulls, animals notoriously difficult to kill, were included. The cause of misfiring was the omission to clean the apparatus, evidently not difficult; the correct sized cartridge for the animal to be killed (three strengths are made) must be used. The use of the bullet was not enthusiastically advocated. Mr. Knight referred to a young slaughterman he had seen through whose hand a bullet had just passed. Mr. J. R. Hayhurst, the superintendent of the Islington abattoirs of the City of London Corporation, on account of the danger ricocheting from the hard floors and walls of the slaughterhouse, did not welcome the idea

of bullets being used on the 10,000 animals killed daily there. However, the London County Council inquiry only elicited five genuine and one suspectedly genuine accidents between 1913 and 1920, five of which occurred with pistols of the free bullet type, and in the remaining case the type of pistol was not specified. These, of course, should be avoided if possible, yet the danger is not very great.

The question of injury to the public health, caused by the alleged more rapid deterioration of meat due to the splashing of minute blood-vessels in the flesh of animals previously stunned by mechanically operated instruments, was again raised. Mr. Dewbury, however, said that splashing could be seen in the flesh of pigs killed by sticking, and that Prof. Gerald Leighton had shown by microscopical examination that the objection of imperfect bleeding could not be upheld. Further evidence is afforded by the inability of skilled and experienced observers to distinguish between the flesh of carcasses bled after felling with the pole-axe and those bled after the use of some humane killer, also by the obligatory use of the instrument in Denmark and Sweden, in spite of their being countries from which large exports of bacon are made to this country, and which in consequence would and could not enforce any particular practice detrimental to the quality of the meat.

The Chairman, Prof. Fredk. Hobday, advocated the formation of a committee of investigation, composed of medical men, veterinary surgeons, butchers, and humanitarians. Reference was made to demonstrations from which the advocates and opponents of humane killing had drawn different conclusions. Mr. Hayhurst thought that neither side was quite sure of the results; should demonstrations by a suitable committee show that "humane" killing was the best method it should be made compulsory throughout the country.

MNEMONICS IN THE STUDY OF HOME NURSING.

IT may be doubted whether mnemonics can ever play a large part in the study of home nursing. That many people find them useful, however, is proved by the publication of a third edition of a book[1] which contains a large amount of useful information arranged in tabular form, and many ingenious words and phrases devised to act as keys to the subject under consideration. In some instances these mnemonics are bewilderingly ingenious. Disinfection must be *sure*, and to attain this it must be S, Suitable for the purpose; U, Undertaken on the spot; R, Reliable and sufficiently potent; E, Effective and sufficiently prolonged. It seems a pity, too, to use mnemonics to emphasise such virtues as personal cleanliness and obedience to the nurse herself, and it is doubtful whether an aid to memory can ever be of much value on such a wide subject as the duties of the nurse towards the patient. The little booklet does, however, contain many good working rules, and may prove useful as a résumé of previous work and wider reading, provided too much attention is not paid to the number of aids to memory scattered through it.

EMBRYO CELL DIFFERENTIATION.

IN his Croonian lecture, delivered last week before the Royal Society, Prof. Hans Spemann (Freiburg) described the transplanting of very small parts of newts' eggs from one embryo to another in order to see whether they would develop in the same way in their new surroundings. Most parts of the embryo were found to be quite indifferent in that they followed the development of the part of the embryo into which they were planted. A piece, for instance, that would have formed part of the brain made a part of the skin after having been grafted into the region of the future skin and vice versa. There was, however, one definite region of the embryo—namely, the mesoderm—which behaved quite differently. Mesoderm removed from one embryo and implanted into a more indifferent region of another, such as the region of the future skin, would not form skin, but would retain its own character and force its new surroundings to follow another line of development. Inasmuch as tissues of this kind "organised" the secondary embryo they were called organisers, and the region where they lay at the beginning of development the centre of organisation. Organisers, said Prof. Spemann, did not act only on embryos of the same species, but also on embryos of different species, of different genera, and even of different orders. Thus, for instance, where an organiser of one species of salamander was implanted into the young embryo of another species it there induced a secondary embryo, partly built up by the implanted cells and partly by the host, the cells of the two individuals being traceable in development. Organisers might also be produced experimentally out of pieces of a more indifferent charac
If such pieces were transplanted into the centre of organ
tion they assumed, after a time, some organising facu
Taken out again and transplanted into a new indiffer
region of another embryo they could now induce ther

organisers, or organisers of the secondary degree.
whole development, at least of these low vertebrates, mi
therefore be thought of as composed of single develop
processes linked together by organisers. As to their me
of inducing the changes, nothing certain was known,
some facts suggested to Prof. Spemann that the means v
chemical rather than dynamic.

[1] Compendium of Aids to Home Nursing (Home Nursing Simplified and Tabulated). Third edition, revised. By W. Corbet Fletcher, M.B., M.R.C.S. London: Bale, Sons and Danielsson, Ltd. 1927. Pp. 109. 1s.

"BAND AID" ADHESIVE BANDAGES.

WE have received from Messrs. Johnson and John
106, Golden-lane, London, E.C., and Slough, Bucks
specimen of a useful protective dressing for minor c
burns, and abrasions. It consists of a gauze pad, on ei
side of which is a strip of adhesive plaster for securing
dressing, the bandage being faced with crinoline cloth
keep it clean until required for use. The bandage car
quickly applied, holds firmly in place, and has a
appearance. It is put up in boxes containing six st
of bandage three-quarters of an inch wide, ready for app
tion to a wound, together with three large pieces which
be cut up into small strips as required, but larger size b
can also be obtained.

THE POWERS OF AN EIGHTEENTH CENTUR BISHOP.

IN what have been termed the Middle Ages of our his
the practice of medicine was almost entirely in the hanc
the clergy, and coming nearer our own time bishops, o
than the Primate at Lambeth, seem to have had the priv
of conferring degrees by which the bearer was entitle
practise the profession independently of the imprimatu
any other body. It is to be inferred from the follo
letter, of which we have received a copy from Miss Be
Couch, of Andover, that, at no very distant dat
bishop laid claim to the opposite right—namely, tha
preventing from exercising the profession in England
person who had taken his medical degree in a for
university. We have not before seen an instance of
enforcement of such a prohibition. The letter runs:—

"May it please your Lordp.

"After most humble Duty presented to your Lord' & a

seven bishops sent to the Tower by James II.

A Review
OF
PROSTATIC ENLARGEMENT.

ing the Bradshaw Lecture delivered on Nov. 10th, 1927, before the Royal College of Surgeons of England

Y SIR CUTHBERT WALLACE, K.C.M.G., C.B.,
VICE-PRESIDENT OF THE COLLEGE AND SURGEON TO ST. THOMAS'S HOSPITAL.

RECENT years have added but little to our knowledge the function of the prostate. It is not apparent at it has any internal secretion, or that it exercises y influence on metabolism; it is a secondary sexual nd. The prostatic urethra above the entrance of e ejaculatory ducts is developed from the urinary upper part of the genito-urinary sinus and corre-onds with the female urethra; the part below springs m the lower part of the sinus and corresponds to e vestibule in the female. It is said that the gland bules of the prostate correspond to Skene's tubules at are found in the female urethra. If this is the se the prostate, like the breast, seems to be an tance of the economy of Nature, for she has modified e-existing structures to her purpose. In some imals, even in the male, the glands, though some-at bunched together, remain separate structures; t in others (as in the dog) they are collected together d form a structure very similar to the human ostate. It is interesting that the dog has a prostate ucturally very like that of his friend, the man, l like the man suffers from prostatic trouble in vanced years.

The glands that make up the prostate spring parently from all sides of the urethra, but the terior group ultimately atrophy. There has been ne doubt as to whether the glands that lie in the dline above the ejaculatory ducts are budded off m the posterior surface of the urethra or whether e glandular elements met with in this position y represent the displaced distal extremities of the nds that spring from the sides of the urethra. is is not a very important point, but it is this nd mass that goes to make up the so-called third e, which has been credited with being the cause most of the troubles that are connected with static enlargement. The gland mass that lies ow the ejaculatory ducts is seldom the seat of nges and usually retains its spongy nature. This nd mass is derived from the lower part of the ito-urinary sinus and has been said to have a arate blood-supply and to be at one period closed in a separate capsule.

Long before birth the prostate has assumed its ult form and the gland tubules the distribution that tains throughout life. There is no indication of y division into lobes or lobules. The tubules run from the side or posterior walls of the urethra ards the sides of the organ, tending to bend ward as the distance from the urethra increases. front there is very little if any gland matter. This ndless area represents an atrophy of tubules, not usion of constituent lobules. None of the tubules the gland reach the surface, thus leaving another n-glandular portion.

Lastly, there is always a considerable thickness of n-glandular tissue surrounding the urethral canal. tside the gland proper lies the pelvic fascia, taining in front and at the sides the prostatic xus, and behind lies the non-vascular fascia of nonvillier. Above the prostate is intimately ded to the bladder, as one would expect, having ard to the method of development.

HISTORICAL.

t is possible to-day dispassionately to survey the tory of prostatectomy. In the eighth edition of chsen's "Science and Art of Surgery," published in 1884, after describing various palliative procedures for enlargement of the prostate, the author continues:—

"Various operative procedures have been recommended and practised by Mercier and others for the removal of the mechanical obstruction caused by the enlarged prostate, but they are both inefficient and dangerous and have been almost unanimously condemned. In fact, the sole treatment of enlarged prostate consists in the regular use of the catheter, and when once this treatment has been commenced it must be continued for the remainder of life."

In the next edition, published in 1888, the above statement again appears with the following addition:—

"Lastly, within the last few months, F. McGill, of Leeds, and Socin, of Leipzig, have advocated the removal of the obstruction by suprapubic cystotomy . . . . he removes the projecting lobe with scissors and forceps or by enucleation with the fingers . . . . it seems hardly justifiable to submit him (the patient) to an operation the benefit of which is doubtful and which may prove fatal . . . . All his (McGill's) cases were undertaken on account of cystitis and other complications, but he suggests the possible extension of the operation to uncomplicated cases."

In 1886 Belfield, of Chicago, attacked the prostate by the suprapubic route.

The following paragraph from a lecture (1908) by our President carries on the history.

"The first suprapubic prostatectomy done in England was performed on March 24th, 1887, by McGill. In that operation and in many subsequent ones he removed only a small portion of the prostate in one piece, or in many pieces, cutting away the projecting and obstructing parts of the gland with scissors. Later Mr. Jessop introduced his 'ring-scissors,' which made this piecemeal removal of the gland an easier matter. The first attempt at enucleating a portion of the prostate in Leeds was made on Dec. 15th, 1887, by Mr. Edward Atkinson. This was during my house surgeoncy, and I quite well remember the enthusiasm the genial operator had for the case, and the simplicity of this procedure. On Dec. 17th, 1887, Mr. McGill employed this method of enucleation; a portion of the prostate, weighing 2 oz. 40 gr. which surrounded the urethra laterally and below, was enucleated in one piece."

McGill's operations were evidently done in cases in which the general condition was extremely bad; from what he says, however, he was obviously looking forward to practising the operation in more favourable cases. Mayo Robson and Mansell Moullin followed the method of McGill. In 1888 Harrison was advocating perineal section and prostatectomy, more especially in those cases of foul urine and degenerated kidneys, and in this way seems to have laid the foundation of the present two-stage operation. In 1893 White, of Philadelphia, reviewed the whole situation and quoted statistics stating that the mortality of the perineal route was between 13 and 14 per cent. and that of the suprapubic between 20 and 25 per cent. It was with the idea of finding a safer method of relieving the patient that White suggested castration. In 1894 Fuller, of New York, performed an operation apparently identical with McGill's procedure. In this same year Nicoll, of Glasgow, and Alexander, of New York, were performing a prostatectomy of similar nature to McGill's, but by the perineal route. During these years there was considerable discussion as to where the obstructing growths lay—that is to say, whether they were intra- or extra-vesical and whether the perineal or transvesical route was the best.

From 1886 until the close of the century the operative treatment of enlarged prostate was undergoing a slow and painful evolution. A certain number of surgeons were practising an operation which was practically similar to the modern one, but they were faced with a heavy mortality and were unable to persuade the profession as a whole to follow their lead. The general feeling of the profession can be gauged by the eagerness with which the so-called sexual operations were taken up. In the late 'nineties the operation of prostatectomy was again making headway and the sexual operations, having been found wanting, were declining. In 1900, while the treatment of enlarged prostate was still chaotic, Freyer published his series of successful cases, which, anyhow

in this country, re-established prostatectomy as an operation of choice.

Since this time the suprapubic operation has found favour with most surgeons and the technique of its performance has remained in the main unaltered, but alterations and improvements have been put forward. The alterations introduced have consisted in the main of a more wide opening of the bladder with the idea of rendering the operation less blind and for a better hæmostasis. I believe that McGill made some attempt in this direction, and in 1907 Rutherford Morison advocated a wide transverse opening in the bladder, a full exposure of the internal meatus, and a removal of the obstruction under the eye. Of recent years this method has been again put forward and practised by Thomson-Walker in this country and by the Mayo Foundation in America. The perineal operation has, on the other hand, found some formidable advocates and appears at the present time to be gaining ground.

THE SEXUAL OPERATIONS.

The history of the sexual operations is interesting and instructive. Castration as a remedy for prostatic enlargement was suggested to White by the shrinking of uterine fibroids after ovariotomy, the uterus being considered a homologue of the prostate. To test his theory White got a friend to castrate adult dogs; they found that atrophy of the prostate quickly followed. In April, 1893, Fredrik, the Norwegian, had made the same observation and performed castration for prostatic enlargement. Later it was found that, in 1775, John Hunter made the classical observation on the want of development of the prostate that resulted from castration in youth or infancy. In 1889 Griffiths reported that atrophy of the prostate followed castration in the adult dog.

Treatment by castration, although put forward academically, was taken up with a rush, and like many new treatments was at first apparently efficacious. Even unilateral orchidectomy was reported to be efficient. In the course of time, however, it was found that castration had a very definite mortality and was said to cause dementia, even if it did not cause death. The literature of the period also shows that castration could not be relied upon to cause an atrophy of the enlarged prostate. Prof. Frederick Hobday, in his book on "Diseases of the Dog and Cat," quotes three instances out of a great number of cases where castration was practised with beneficent results for enlarged prostate in the dog.

Vasectomy was next proposed as a slighter operation, but one warranted to produce the same effect. It had a vogue, but gradually it also lost favour and with it the sexual operations ended. It was supposed to act by causing an atrophy of the testicle—that is, virtual castration—and thereby an atrophy of the prostate. It was suggested as an alternative to castration because some observer noticed that atrophy of the testicle followed section of the vas, when this was accidentally divided in the course of an operation for varicocele. Now this observation, though it led to the extensive practice of vasectomy, was erroneous. What really happened was that division of the vas cut off the last remaining blood-supply of the testicle; the testicle atrophied from lack of blood and not on account of the division of its duct.

Mr. Shattock and I did some experiments to find out the truth of this matter, and we found that, while cutting off the blood-supply caused an atrophy of the testicle, division of the duct left the testicle entirely intact. While in the midst of these experiments we found that John Hunter had made the observation in the human subject that the testicle developed and contained spermatozoa although there was no connexion between the testicle and its excretory canal. In 1825 Astley Cooper, using a dog, divided the vessels of the cord on one side and the vas on the other. The testicle whose vessels had been divided sloughed, but the organ with the divided vas slightly increased in size. In 1829 the dog was killed and the epididymis was found full of spermatozoa; the testicle was normal. The specimen, No. 4289, is the Hunterian Museum. This experiment w repeated by Curling in 1842, by Gosselin in 1853, a more recently by Griffiths.

There are, therefore, in the above history t instances of knowledge acquired by experiment a then forgotten and buried, but rediscovered at a la period. In vasectomy, as practised for the relief prostatic enlargement, we have an example of h careful one must be to verify the facts before applyi them.

CAUSATION AND NATURE OF THE ENLARGEMENT

Two theories as to the nature of prostatic enlar ment have alternately held the premier place—name the infective and neoplastic. Nothing of interest this connexion has come to light of recent yea except that Hugh Young, by a careful statisti inquiry, has shown that gonorrhœa, at all ever plays no part in the ætiology.

At present most people regard the enlargement due to the growth of adenomata, and if this is accep the cause of prostatic enlargement is the same as t of other such growths. In this association it may useful briefly to allude to certain facts :—

1. The growths reproduce fairly faithfully the histolog features of the parent, both as regards stroma and gl tissue.

2. Encapsulation is usually very complete, especially old-standing cases.

3. Sometimes, however, the encapsulation is incomp and recalls certain adenomata of the breast.

4. The growths are often compound, one adenoma com ing several small ones.

5. The time of appearance is late in life and this may h some connexion with

6. The proneness of the growths to become carcinomat

7. The statement of some observers that the alveol the growths maintain a connexion with the excretory d and can be injected from the urethra if suitable means taken.

Point of Origin of the Adenomata.

There is still some difference of opinion as to exact place in the gland at which these masses a One school maintains that they are not true prost tumours, but arise in the subcervical or in the gla of Albarran, both of which are submucous. It m be in certain cases that this is their point of ori but in far the greater number the point of origin well within the prostate proper. Examination number of prostates about the age when the dis commences has shown that the white areas which the first indication of change from the normal spo prostate tissue lie a long way from the urethra, gradually they enlarge and approximate that ca and finally, when they come to operation, are covered by a very thin layer of urethral mu membrane. The adenomatous masses usually aris connexion with the acini which enter the prost urethra above the mouths of the ejaculatory du that portion of the gland which lies below seems little prone to this change and often retains normal spongy texture after the rest of the gland undergone a complete change. It is interesting to that the immune portion of the gland is appare developed from those tubules which are conne with the lower part of the urogenital sinus and with the urethra proper, and have been stated some observers to be surrounded by a distinct fib coat in the early stage of their development an have a separate blood-supply.

CAUSATION OF SYMPTOMS.

The symptoms must be of local origin, since bla function returns to practically normal when obstruction has been removed.

The symptoms can be discussed under the follo heads: frequent micturition, precipitate micturi hesitant micturition, dribbling after micturi interrupted micturition, and residual urine.

Frequent and precipitate micturition may explained by thinning and then replacement of

ontractile tissue about the internal meatus by the denomatous growth.

Hesitant and interrupted micturition are more difficult of explanation. Hitherto they have been put down to the ball valve action of the "third lobe." Now growth behind the urethra that could act in this way s a rarity, and I would suggest that these symptoms re caused somewhat in the following way. The rethra is surrounded by an adenomatous mass which s under tension caused by its growth stretching the athological capsule. The urethra is also bent at an ngle so that it forms a kind of flap valve. In order for rine to pass the pressure in the bladder has to be so djusted that it can overcome the increased pressure ithin the urethra and at the same time be insufficient o shut the valve. Any departure from the optimum ladder pressure will cause a cessation of the flow of rine. The distressing symptom of dribbling from the rethra after the act of micturition should have been nished may be accounted for by the elongation, tretching, and distortion of the canal by the denomata which have replaced the normal contractile ssue or hindered its orderly action.

Residual urine is most difficult of all symptoms to xplain—in fact, it never has been explained. The ost ingenious solution that has been offered is that hich attributes it to the intravesical pressure on ie varying cone-like projection of the prostate into ie bladder. When the bladder is full the cone will roject but little, but as the organ empties the cone ill offer a greater surface that is subject to pressure, ith the result that the urethra becomes occluded. nfortunately for this explanation, a vesical cone is ot always present.

I would suggest that residual urine is really a case bladder posture. Fullness of the bladder is a lative term. The usual act of micturition, when ce the initial stimulus of distension has been given, a continuous one. In the process of emptying the adder will contain from time to time an amount urine which in process of filling had produced no sire for micturition. If the act of emptying is ow or interrupted, as it is in prostatic trouble, it possible to imagine that the impulse necessary to rry the act to completion becomes dormant or fails be again initiated; to speak in homely terms, the adder imagines itself to be empty.

FATE OF THE CAVITY LEFT BY OPERATION.

Even before the revival of prostatectomy in this untry it was asserted by those who practised this eration that the procedure consisted in the total moval of the prostate. This assertion was reiterated this country and given as an explanation of the ccess of the operation. This was fortunate, since led to a proper appreciation of the morbid changes hich are taking place in the gland. It is now, I ink, admitted by most people that the modern eration for prostatic hypertrophy consists in ucleation of adenomatous masses from within the panded outer portion of the organ, and that there no real solution of continuity in this operation tween the bladder and the urethra. That fact counts in part for the almost unbelievable fact that s operation is very seldom followed by stricture. e process by which the healing of the urethra is ought about is worthy of a little consideration.

After the enucleation the urethra and bladder are ined by a ragged cavity, which may be at that oment of very considerable dimensions. Very soon er the removal of the adenomata, or rather at the ry moment of their removal, the cavity contracts ntripetally, so that not only are the sides of the vity brought together, but the bladder is at the me time approximated to the urethra. This contrac-n is caused by the resilience of the remaining rt of the prostate, and it may be remembered that s this resilience pressing on the central adenomatous ss which is in part the cause of the urinary diffi-lties. This contraction at the time of operation a very real thing and gives rise to considerable ficulty if the surgeon wishes visually to explore the cavity. After the operation the cavity continues to retract, so that in some cases within a few weeks a skiagram of the bladder shows no sign of its existence. Sometimes, however, a distinct cavity remains for a considerable period, though micturition is perfectly normal. It might be argued that the existence of this cavity shows that the internal sphincter is out of action. There is, however, another explanation. It is possible in those cases in which a cavity persists that the growth has been largely intravesical and that the top of the cavity corresponds not to the internal sphincter but to the level to which the mucous membrane of the bladder has been raised.

The contraction of the cavity may be looked upon as one of Nature's means of hæmostasis, and this consideration may raise some doubt as to the wisdom of habitually using a dilating device as a means of avoiding hæmorrhage. The retraction of the cavity is important in another direction, since it reduces the surface to be covered by epithelium.

When opportunity occurs of inspecting and digitally examining a bladder after a prostatectomy, it is remarkable how little abnormality is to be made out. Perhaps a small dimple at the internal meatus, or the meatus is not so dilatable as it normally is, and reminds one of the state of affairs in carcinoma or in the so-called "Mercier's bar." Again, it is almost impossible to be sure by rectal examination as to whether the prostate has been removed or not. Museum specimens of bladders after removal of the prostate are comparatively rare, and more are required for investigation; but the one in the Hunterian Museum, presented by Sir Rickman Godlee, shows very well what little distortion remains after operation.

THE TWO-STAGE OPERATION.

The two-stage operation was introduced quite early in the history of prostatectomy to rest the patient who was worn down by sepsis and want of sleep. The indications for its performance were at first almost entirely clinical.

The discovery and perfection of tests of urinary efficiency have extended and rendered more accurate the indications for the performance of this operation. It entails, however, certain disadvantages:—

1. There are two anæsthetics and two periods of anxiety and discomfort.

2. The enucleation is made more difficult by the shrinking of the bladder, the hardening and contraction of the prostate, and the induration of the abdominal wall. In addition the wound may become foul and phosphatic deposit give trouble.

If the two-stage operation is decided upon, the relative merits of catheter and suprapubic drainage are to be considered.

The catheter has been, with many surgeons, very successful; it avoids two operations, but it may give rise to a urethritis which is troublesome and in some cases to a definite rise in the blood-urea.

The suprapubic cystostomy has the great advantage that the condition of the prostate can be accurately determined by the only certain way—namely, that of bimanual examination.

Urinary Efficiency.—There are, of course, discrepancies between the various tests or parts of the same test, but in the main one is able to form a fairly just estimate as to the efficiency of the kidneys. But mention must be made of what is to me at all events a difficult problem. When is the surgeon justified in refusing to proceed to a second-stage prostatectomy?

There are a certain number of patients on whom a drainage cystostomy has been performed and whose urinary efficiency, as judged by the usual tests, has never fallen to a figure that would, in the first instance, have warranted a single stage prostatectomy, although in other ways they seem to be in good health. The question to be decided is this: What percentage of urinary efficiency is to be taken as justifying a completion of the operation after a period of drainage?

After-treatment.—I have nothing to say about this subject, except to express the opinion that whatever is the means favoured to carry off the urine after prostatectomy, the less the prostatic couch is interfered with the better. My cases have been very free from secondary hæmorrhage, and I attribute this to washing the bladder out only in exceptional circumstances.

BACK PRESSURE.

The mechanism whereby the loss of efficiency of the kidney is brought about is still unsolved. It is doubtful what effect the obstruction to outflow has on the constituents of the urine and what is the ultimate fate of a kidney whose duct has been completely occluded for varying periods. The rapid improvement that takes place in some cases after drainage of the bladder is mysterious. Perhaps the easiest explanation is that which attributes recoverable damage to vascular compression and not to histological change. It is usual to simply attribute the troubles of the kidney to "back pressure" and to leave it at that. When the subject is examined more carefully it is not so easy to understand how the kidney is subjected to an obstruction lasting over a long period.

It is not very obvious why we speak of back pressure in connexion with the kidney and do not use the term when we talk of obstruction in connexion with other ducts and the intestinal tube. It is an unfortunate expression, because it sometimes leads to the belief that the pressure which injures the kidney originates in the bladder as the result of tension or of muscular contraction. The pressure that dilates the ureter and destroys the kidney is the secretion pressure of the kidney, but it may be of interest to consider what are the pressures in the bladder that hinder the ureter in propelling the urine into the bladder; so long as the ureter can get rid of the urine, the kidney will be shielded from any noxious pressure.

I am indebted to Mr. B. W. Williams for the following observations incorporated in Table I.

TABLE I.—*Pressure in Bladder in Cases of Retention.*

Case No.	Duration of retention.	Bladder pressure in mm. mercury.	Amount of urine in ounces.	Case No.	Duration of retention.	Bladder pressure in mm. mercury.	Amount of urine in ounces.
1	36 hrs.	8–10	35	6	12 hrs.	34	46
2	7 days	23–25	85	7	24 ,,	27	50
3	48 hrs.	22–23	45	8	24 ,,	16	50
4	Overflow	19	20	9	22 ,,	8–10	36
5	3 days	29	42	10	24 ,,	24	40

They show the pressure in the bladder of some cases of retention. They were taken by means of a water gauge and have to be reduced to millimetres of mercury, as more readily appreciable. The pressures recorded are those found in the intervals between spasms of the bladder.

From this table it will be seen that the maximum pressure that the ureter has to overcome in a case of acute retention of urine is about 34 mm. of mercury. The pain occasioned at such a pressure is not to be endured; the individual is compelled to seek relief. From this it appears that any high pressure that may act injuriously on the kidney must be of very short duration.

In most cases, and even in cases with a considerable amount of residual urine, the pressure against which the ureter has to work must be very slight. In fact, it is difficult to see that the pressure in the bladder in most cases of residual urine can be greater than that which pertains in the ordinary course of filling of the bladder. It follows that there are three possibilities:—

(1) That the kidney is extremely sensitive to any obstruction, or

(2) That the damage done is in the nature of a sudden catastrophe (during an attack of retention), or

(3) That we must seek some unknown cause of kidney deterioration.

SUPRAPUBIC AND PERINEAL OPERATIONS COMPARED.

While the suprapubic method has been chosen by the great majority of surgeons, the perineal has been practised by surgeons of great repute and experience, one of whom has probably the lowest mortality of anyone. It is therefore useful to inquire if there is any cause for the majority to change their methods.

It is claimed that:—

1. The perineal is the more scientific, in that the enucleation is more deliberate and performed under the eye.
2. The ejaculatory ducts can be saved or ligated.
3. The urethral wall can be left intact.
4. The loss of blood is less.

To take these points one by one.

1. Some surgeons might say that by using a large vesical incision the enucleation can be carried out as openly and as deliberately by the suprapubic as by the perineal route. Putting this contention aside for the moment, it may be considered as to whether the enucleation under the eye is a material advantage. Removal of the adenomata is not a matter of delicate and difficult dissection, but really consists in entering a line of cleavage already established and following it to its conclusion. It therefore matters little whether this is done under the eye or not. An accurate judgement that all adenomata have been removed can be ascertained by bimanual examination when the suprapubic route has been used.

2. As regards the preservation of the ejaculatory ducts, if it could be shown that children had been born to patients who had undergone perineal prostatectomy it would be a point in favour of that operation as a restoration ad integram is always desirable. I am unaware, however, that a man has ever begat a child after a prostatectomy. As regards a man's virility, apart from power of procreation, we have already seen that section of the vas produces no effect. It is not very clear as to whether the occurrence of epididymitis is caused or prevented by rupture of the vas. If opening the canal can cause an infection to spread to the epididymis, it cannot be denied that infection can occur with an intact vas or one in which the lumen has been obliterated by ligature after rupture. In the matter of the vasa, therefore, it does not seem that the perineal method has any advantage over the suprapubic operation.

3. My observations on many post-mortem and operative specimens have led me to doubt the possibility of leaving the urethral wall intact in any but a very small and insignificant number of cases, and I should not be influenced on that account in the choice of the operative route.

4. If excessive bleeding could be certainly and effectively diminished by the perineal route that would be a very good argument in favour of its adoption.

5. As regards restoration of function and absence of a persistent operative sinus, the suprapubic method leaves little to be desired.

Prof. Hans Wildbolz in a recent communication has advocated the use of the perineal method and the suture of the neck of the bladder and the distal portion of the prostatic urethra. He also states that the mortality of the operation is less than that of the suprapubic method, that the former method leads to a smaller rise in the blood-urea, and that sepsis is practically abolished, and that union takes place per primam. If other surgeons can reach the same results it will be a great argument in favour of the perineal method.

One fact in favour of the perineal route seems to be connected with the treatment of prostatic carcinoma. If this operation justifies its performance and if it is considered that the prostate can be best excited by this method, the more surgeons familiarise themselves with its technique the better.

Best Time for Operation.

It is fortunate that, although the adenomata may be multiple, they are usually all of an age, so that when they have necessitated operation their removal

hardly ever followed by the formation of others. should be the aim of the surgeon to remove the bstruction before the urinary function is depressed.

If the prostate is large and resilient and the life of ie patient is disturbed by his trouble the decision operate presents no difficulties. On the other hand, the prostate presents no great departure from the ormal and the patient is willing to put up with what scomfort he has, most surgeons would, I think, be illing to wait, provided the kidneys are efficient and ie patient can be watched.

Some statistics that I will bring forward later seem point to the fact that the mortality of prostatectomy nyhow in hospital patients) will not be reduced until e cases present themselves for earlier treatment. ore difficult are those cases in which the life of e patient is being somewhat disturbed by urinary oubles and examination per rectum shows a prostate rhaps a little large, but not much altered in shape size. Such a case may prove to be a simple prostate nich has not greatly enlarged or not enlarged toward e rectum, a case of carcinoma, or "prostatic bar." know of no sure way in which the matter can be ttled except by opening the bladder and a bimanual lpation.

It has been truly remarked that if an individual is stined to have trouble with his prostate he is lucky the organ, so to speak, ripens quickly, about the e of 60. The kidneys will most probably be in good ndition, a single-stage operation is possible, and ere is a prospect of many years of health and joyment of life.

CARCINOMA.

Up to the present it cannot be said that the atment of carcinoma has been satisfactory, either m the operative or radiation point of view. The erative treatment involves the entire removal the gland. This is a difficult and tedious procedure. has been accomplished, however, in a limited mber of cases by the perineal and by the trans-ic routes and the feasibility of a satisfactory union the bladder and urethra demonstrated.

If the mechanical difficulties of removal have been t over, it cannot be said that the difficulties of gnosis sufficiently early to justify a serious opera-n and offer a reasonable prospect of cure have en surmounted. Herein, to my mind, lies the ix of the question. The diagnosis of carcinoma is ually made on the hardness, the nodularity, the ation of the prostate as felt per rectum, and the lasticity of the internal meatus as felt from the dder. By the time that the signs of malignant ease are irrefutable, as judged by a rectal or stoscopic examination, the time of successful inter-ntion is probably passed. The rigidity of the internal atus, which is a useful sign, can only be ascertained er a suprapubic cystostomy, which is a distinct advantage if the prostate is to be excised by the rineal route. Again, there is the difficulty of gnosing carcinoma from that undifferentiated up of affections that may be classed under the m "post-urethral bar."

Adenocarcinoma in its own way presents almost great a difficulty to the surgeon. This condition y be diagnosed in the process of enucleation of presumed adenomatous mass, or it may not be gnosed until after a microscopic examination. re the surgeon has three courses open to him:—

. He can proceed forthwith to a total extirpation of prostate, whose removal will have been made all the re difficult by the already accomplished operation.

. He can wait and put the matter before his patient.

. He can allow the bladder to close, if it will, and establish suprapubic drain when obstruction supervenes, which ually happens within six months.

IRRADIATION.

This has been carried out from the urethra, from rectum, by means of needles introduced through perineum or through the bladder; deep therapy s also been used. Irradiation in the case of carci-na of the prostate is in the same condition as irradiation for carcinoma in other parts of the body We are slowly and painfully groping our way towards a better knowledge. There are many groups of observers doing good and careful work throughout the country, but I cannot help wishing that someone who has the means would by his generosity render possible a more intensive study of the subject.

Prof. Sidney Russ, of the Middlesex Hospital, has kindly prepared for me Table II., which shows

TABLE II.—*Estimates of Publicly-owned Radium (1927) for Medical Purposes.*

Country.	Population (millions).	Grammes of Radium.	Grammes per million of population.
France	40	18	0·45
Belgium	7·5	4	0·53
Denmark ..	3·3	2	0·59
Sweden	6	2·65	0·44
Germany	56	2	0·04
British Isles ..	45	11·5	0·25
Australia	6·2	10	1·60

an estimate of the radium publicly owned in the countries named. The figures for the British Isles include the radium held by the London, Manchester and Glasgow institutes.

MORTALITY.

It is extremely difficult to arrive at a just mortality of any operative measure. The mortality of operations in private practice is almost always better than that in hospital, owing to the different social classes from which the patients are taken.

I may give in the first place a few instances of figures given by individuals. In 1893 White, of Philadelphia, as we have seen, gave the mortality of the perineal route as between 13 and 14 per cent., and that of the suprapubic as 20 to 25 per cent. In 1912 Freyer gave the mortality in 1000 cases as 5½ per cent. and stated that in the last 100 cases it had fallen to 3 per cent. Hey Groves, commenting on these figures, said that he had taken the mortality for all the available large hospitals in the kingdom and found it to be 40 per cent. Hugh Lett, in 1913, said he believed that the mortality of hospital patients was 20 per cent. Fullerton stated in the same year that his mortality in 55 cases was 7·2 per cent.

Hugh Young, in his "Practice of Urology" (1927) gives his mortality for the perineal operation as 3·4 per cent. in 1049 cases, and Wildbolz just recently has stated that his mortality for the suprapubic method (105 cases) is 15 per cent. and for the perineal operation (305 cases) is 6·5 per cent. These figures show very real differences.

Through the courtesy of some surgeons I am able to show some figures from different hospitals which are a good guide as showing the results in one class of patients. (Table III.)

TABLE III.—*Mortality of Operations in Four London Hospitals.**

—	Total.	Died.	Mortality.	Individual mortality.
Enlarged prostate	831	131	15·8	13·1; 13·5; 17·8; 20·1
Prostatectomy	621	88	14·2	12·9; 14·5; 17·5; 20·8

* The figures are the last available.

An absolute mortality has a definite value, but a more satisfactory way is to contrast two sets of comparable statistics. This I can fortunately do. Mr. Max Page, in the Hospital Reports for 1910, published the results of prostatectomy at St. Thomas's Hospital and one can compare these with our more recent figures. (Table IV.)

It is at once apparent that the mortality from prostatic trouble has not materially fallen; that of prostatectomy has fallen from 20·2 per cent. to 14·5 per cent., but the total operative mortality has

somewhat risen. It will be seen that the surgeon has been more chary in performing the one-stage operation and that the deaths that formerly would have been recorded under prostatectomy are now to be found under cystostomy. If hospital statistics

TABLE IV.—*Mortality of Operations for Simple Enlarged Prostate.*

Treatment.	1906–1910. Total cases, 131. Died, 28.				1922–1926. Total cases, 219. Died, 44.					
	S.P. pros.		S.P. cyst.		S.P. cyst.		S.P. pros.			
							Two stage.		One stage.	
	T.	D.	T.	D.	T.	D.	T.	D.	T.	D.
	69	14	20	4	41	21	77	9	68	12
Method mort.	20·2		20·0		51·2		11·7		17·6	
Pros. mort.	20·2		—		—		14·5			
Total op. mort.	20·2				22·5					
Total mort.	21·7				20·1					

S.P., pros. = suprapubic prostatectomy. Cyst. = cystostomy. Op. mort. = operative mortality. T. = total; D. = died.

are to be improved, the patients must seek help earlier than hitherto. A striking fact is the good results that follow the two-stage operation in spite of certain disadvantages.

In conclusion, I think one may say that, whatever is the true mortality of prostatic enlargement, the outlook for the prostatic has improved out of recognition since 1886.

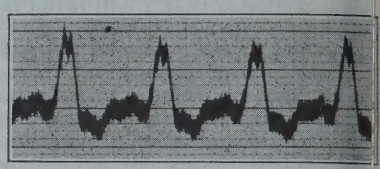
THE PACEMAKERS OF THE HEART.

BY JOHN COWAN, M.D. CAMB., D.SC., F.R.F.P.S. GLASG.,
PHYSICIAN TO THE ROYAL INFIRMARY, GLASGOW;
AND
GEOFFREY B. FLEMING, M.B.E., M.D. CAMB., F.R.F.P.S. GLASG.,
ASSISTANT PHYSICIAN TO THE ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.

IN the healthy individual the rhythm of the heart is almost regular, though the rate varies from time to time with emotion, changes in position, exertion, fever, &c. The wave of contraction starts at the junction of the superior vena cava and the right auricle, flows over the auricles, and then spreads to the ventricles. There is, however, a difference in the course of the contraction in the auricles and in the ventricles. In the former the contraction starts at the sino-auricular node and spreads radially throughout the auricular muscle. In the latter the stimulus, reaching the auriculo-ventricular node, passes along the auriculo-ventricular bundle and its branches, from which it is distributed in an orderly way to the several parts of the ventricles. The electrical complexes of the auricular and the ventricular contractions are thus different. The auricular complex is a simple round-topped deflexion, the representative of a uniformly spreading contraction throughout the muscle. The ventricular complex, on the other hand, is composed of four deflexions, two of which are positive and two negative. These represent the peculiar orderly spread of the contraction to the several parts of the ventricles. The auricular complex is the same for everyone. The ventricular complex of the healthy individual, on the other hand, is characteristic, and continues even to the most minute detail from year to year. But from any cause the normal pathway of the stimulus through the ventricular muscle is broken, the ventricular complex is at once altered, as, for example, in bundle branch block (Fig. 1), where the four deflexions are abolished, and replaced by two of wholly different form.

The rhythm of the normal heart, as judged by the finger or the ear, is quite regular, but if accurate measurements of tracings are taken the regularity is found to be but relative, as the pulse periods vary by fractions of a second. In many individuals, however, the apparent regularity of the pulse is interrupted from time to time by extrasystoles. These may arise in any part of the heart—the auricles, the ventricles, the connecting pathway the auriculo-ventricular node, the bundle, and its branches. Usually they arise in some part of the primitive cardiac tissues.

FIG. 1.



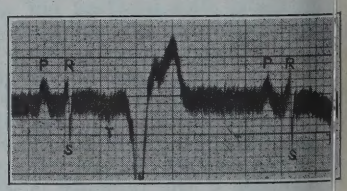
Bundle branch block. Lead I.

Extrasystoles.

Extrasystoles present special characters according to their site of origin. In Fig. 2 a ventricular extrasystole is shown. The first complex is practically normal, the auricular P being followed after an interval of normal length by R, S, and T. The second beat is premature, and quite different from the first. The initial deflexion is downward and its duration is longer than the R's of the first beat, while the second deflexion is in the opposite direction upwards. The irregularity on the upstroke of the second deflexion marks the occurrence of the auricular contraction. The third beat is normal, a replica of the first.

The abnormal character of the ventricular complex shows that the contraction originates in an abnormal site. The increased duration of the first deflexion shows that the stimulus is travelling through the muscle in an abnormal way. The large size of the T shows that the termination of the ventricular contraction is also abnormal. The beat is not merely premature; it is abnormal in its site of origin and in its mode of contraction, as well as in its rhythm. Such an abnormal complex has been shown experimentally to be due to the contraction arising in the left ventricle.

FIG. 2.



Ventricular extrasystole. Lead II.

In auricular extrasystoles, on the other hand (Fig.), the ventricular deflexions are normal and exactly similar to those which obtain with the regular rhythm. The fifth auricular complex is premature, but otherwise normal in character, as the stimulus always passes in a radial manner through the auricular muscle. As the stimulus is premature, conduction has not quite recovered from its last activity, and in consequence the P–R interval is longer than that of the normal beats. But as soon as the stimulus has traversed the auriculo-ventricular node and bundle it passes onward through the usual channels to the ventricular muscle, giving rise to a normal ventricular complex.

In nodal extrasystoles (Fig. 4) the ventricular complex is also normal, as the stimulus reaches the ventricle through the normal channels. The auricular complex is abnormal, a single deflexion but *inverted*,

showing that the stimulus, arising in the vicinity of the auriculo-ventricular junction, has passed *backwards* through the auricular muscle.

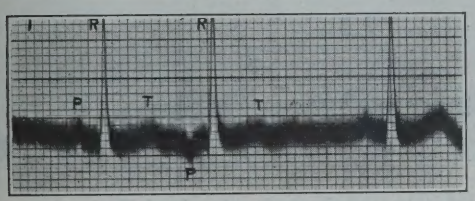
Paroxysmal Tachycardia.

In extrasystole when the dominant rhythm of the heart is normal, with the auricles and ventricles responding in sequence to stimuli which arise in the sino-auricular node, the dominance of that node may be interrupted from time to time by the occurrence of a contraction which originates in some other part of the heart. In some cases, however, the dominant rhythm may be abnormal, as the contractions of the heart are due to stimuli arising regularly in some other part than the sino-auricular node. This is well seen in paroxysmal tachycardia, which is really a series of extrasystoles continuing indefinitely. Any form of extrasystole, ventricular, auricular, or nodal, may be responsible.

In Fig. 5 all the complexes are similar and exactly the same as those of the ventricular extrasystole shown in Fig. 2. The tachycardia is ventricular in origin, all the beats originating in the left ventricle.

Fig. 6 shows an auricular tachycardia. The first two beats are of sinus origin, P regularly preceding Q, R, S. But the second S is followed by *two* positive deflexions,

FIG. 4.



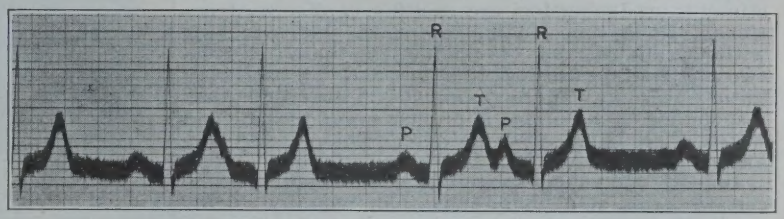
Nodal extrasystole. Lead II.

the second of which is evidently the normal T of the beat as it succeeds R after a interval of normal length. The first deflexion is then a premature P, which is followed after an unduly long interval by an R, which is appreciably smaller than those of the infrequent rhythm. The succeeding T's are all of large size and long duration, evidently the result of the fusion of T and P. (Such an occurrence can be seen in the second complex of Fig. 3 where the auricular contraction occurs so early that it is intermingled with the T of the preceding ventricular contraction, and not immediately after it, as in beat 5.) For the next 2 beats T and P remain inseparable, and the paroxysm then ends as abruptly as it began.

Fig. 7 shows a paroxysm of nodal tachycardia, P being inextricably fused with the ventricular complex, probably occurring synchronously with and deforming S. In Fig. 8 P is inverted and precedes R.

In all these three records the ventricular complex is similar to that of the infrequent rhythm, an indication that the stimulus is reaching the ventricle through the usual channels, bundle, branches, &c. The dominant rhythm of the heart may also be abnormal in cases

FIG. 3.

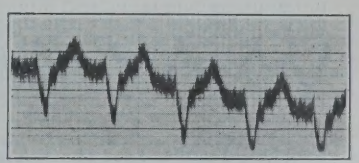


Auricular extrasystole.

where the rate of the contractions is not frequent. The infrequent nodal rhythm shown in Fig. 9 has normal ventricular complexes throughout which are exactly similar whether in response to a normal auricular contraction as in beat 1, or to those of the inverted P's in beats 3, 4. The change of pacemaker in this case is abrupt, though the rhythm and the rate of the cardiac contractions remain unaltered.

It is not always possible to distinguish between auricular and sinus rhythm if the rate is frequent. In auricular extrasystoles the form of the auricular deflexions is similar to that of sinus origin. If the rate is frequent the short duration of diastole causes a prolongation of the P–R interval, but if the rate is infrequent the increase may be imperceptible. Some of the cases of so-called juvenile irregularity, which are commonly ascribed to variations in the sinus rate, may perhaps be due to the occurrence of auricular extrasystoles.

FIG. 5.

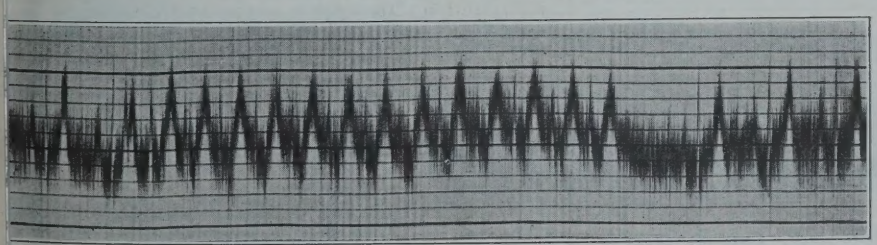


Ventricular tachycardia. Lead III.

Parasystole.

It is thus apparent that the cardiac contractions may be due to stimuli arising in various situations in the heart, in auricle, auriculo-ventricular node, or in the ventricle itself, as well as those which originate in the normal site, the sino-auricular node. A single abnormal beat may occur, or a series of beats which may continue indefinitely. The new pacemaker may produce either a frequent or an infrequent pulse-rate. The onset and the termination of the paroxysm are usually abrupt, but the alteration may occur without any change in either the rhythmicity or the rate of the pulse. A change in the rate of the pulse may be due to a change in the site of the pacemaker, as well as to alterations in the rate of production of stimuli at the sinus node. In the foregoing examples we have seen the functions of the normal pacemaker of the heart usurped by an abnormal pacemaker. either for the single beat of an isolated extrasystole, or for a series of beats. But it may happen that the normal pacemaker and an abnormal one function side by side.

FIG. 6.



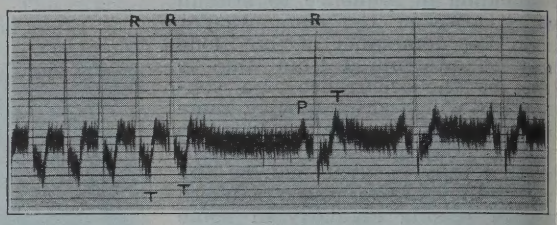
Auricular tachycardia. A premature auricular contraction occurs after two normal beats. This is the first of a series of stimuli of high frequency which throw the heart into a paroxysm of tachycardia.

The simplest example is full heart-block, blocking of the passage of the normal stimulus from the auricle to the ventricle. In this case the auricles respond to stimuli arising in the usual site, while the ventricles obey stimuli arising in the auriculo-ventricular bundle below the node. This is well shown in Fig. 10, where the auricles are pursuing a regular rhythm of 110 per minute, while the ventricles are unaffected by the auricular contractions, and contract at a slower rate, 44 per minute. It seems clear that in such cases *two* stimulus-producing foci are exciting cardiac contractions. It is conceivable, too, that even in cases without disturbance of conduction there may be two active stimulus-producing foci, and that each may initiate cardiac contractions, the heart sometimes responding to a normal stimulus, sometimes to one which arises in an abnormal site. This condition is known as "parasystole."

In 1912 one of us [1] suggested as an explanation of certain forms of allorrhythmia that "the rhythmical production of stimuli at an abnormally irritable point in the ventricles may produce rhythmic irregularities." It is to Kaufmann and Rothberger,[2 3 4 5] however, that we owe not only the term "parasystole," as they have named the condition, but an extremely thorough investigation of the subject, both clinically and experimentally. They bring forward strong evidence to show that most of the forms of allorrhythmia, due to abnormal stimuli arising either in the auricle or in the ventricle, can be explained by supposing that two pacemakers are regulating the heart's action at the same time; that both are coincidently building up stimuli; and that whenever either is ripe to initiate a cardiac contraction and finds the heart muscle responsive a contraction ensues which originates now in one place, now in the other. They suggest, indeed, that all extrasystoles may be parasystolic.

One serious objection to this hypothesis at once arises. Immediately after a cardiac contraction all the functions of the heart muscle (except tonicity) are in abeyance. If stimuli are forming at two centres (the physiological one and another) both would be abolished after each systole and would begin to develop once more during diastole. It is clear that in this case the one which developed fastest would control the cardiac rhythm, as the other would never have a chance of acting. It is possible that this is what occurs in paroxysmal tachycardia. To surmount this difficulty it is supposed that in parasystole the abnormal stimulus-producing centre is in some way protected from the destructive effect of the physiological contraction. In our earlier paper [1] on the subject we made the tentative suggestion that "the irritable focus lies in what may be called a backwater of the primitive cardiac tissue, and that while stimuli can stream down this backwater, physiological stimuli passing down the main channel are unable to disturb the point where ventricular stimuli arise." Kaufmann and Rothberger termed this "Schützblockierung," meaning that there is an uni-directional block which protects the abnormal irritable focus.

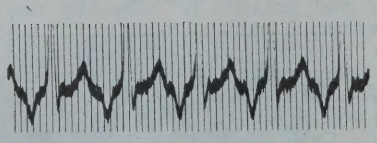
FIG. 7.



Nodal tachycardia. Termination of paroxysm. Lead II.

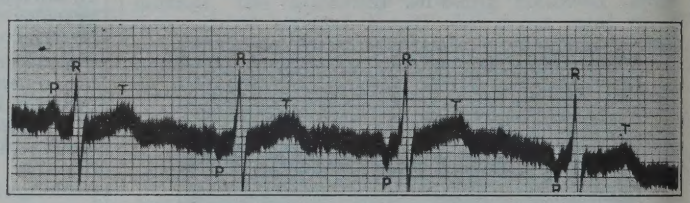
Many theories as to the causes of extrasystoles have been advanced. It is a commonplace that they may be induced by sudden emotion. They occur in acute and in chronic myocarditis. They are often produced by toxic agents such as tobacco, and Bourne [6] has suggested that in some cases a local anoxæmia, from some local narrowing of a coronary artery, may be

FIG. 8.



Nodal tachycardia. Lead II. (J. K. R.)

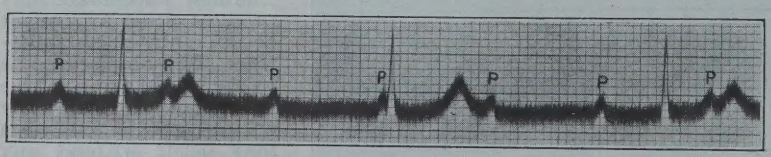
FIG. 9.



Nodal rhythm; no change in rate. Lead II.

their cause. Cowan and Ritchie [7] have argued that an undue distension of an auricular or a ventricular cavity may occasion an extrasystole. It has been shown experimentally that they may be produced by clamping the aorta or the pulmonary artery, the extrasystole arising in the left or the right ventricle according to the site of the clamp. In heart-block, both partial and complete, an extrasystole may occur if auricles and ventricles contract simultaneously. An auricular extrasystole not infrequently succeeds a ventricular extrasystole if in the former the auricular and the ventricular contractions coincide. Even an undue prolongation of diastole, with its accompanying over-distension of the cavities, may be followed by an extrasystole. Lewis suggests that just as circus movements are the cause of auricular flutter, re-entrant waves from the preceding contraction may produce them. It seems probable that the cause of an extrasystole is not always the same.

FIG. 10.



Full heart-block. Lead II.

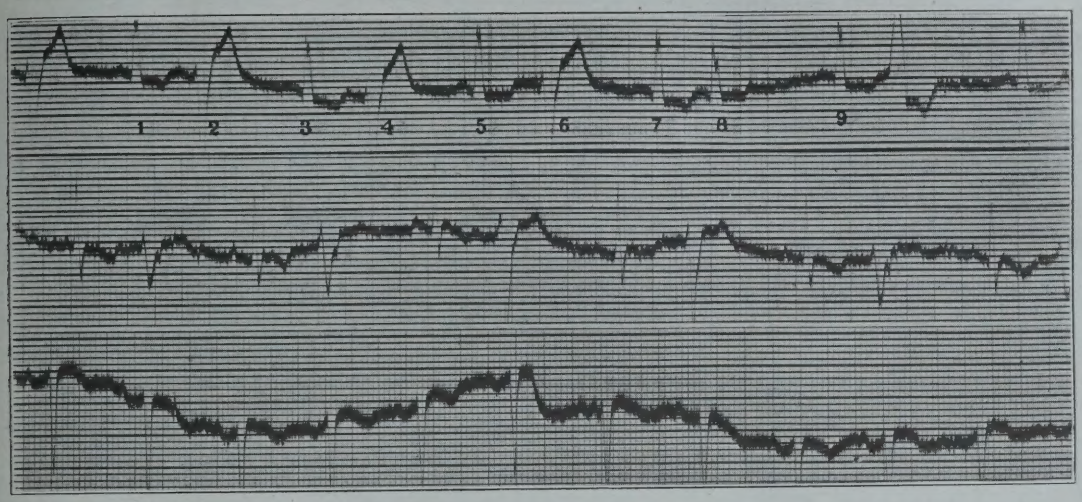
The causes of allorrhythmia, too, are still undetermined. There is an essential difference between the various theories. Parasystole presupposes that the abnormal beats originate in the heart itself, independently of external influences. Cushny has shown that this may occur in digitalis poisoning, the ventricles taking on a rhythm of their own, the rate of which increases until it approaches or exceeds that of the auricles. This is not the result of failure of conduction of the impulses from auricle to ventricle, for in that case the rate of the ventricles would be that seen in heart-block from other causes. It may, too, occur when the auricular rate is infrequent from

nhibition. The heart thus develops two rhythms: one, in the auricles, in response to impulses arising n the normal sinus pacemaker, the other, in the entricles, in response to impulses arising within the entricle itself, from an "increased spontaneity" of he ventricular muscle.

The other theories suggest that the abnormal beat s "forced," as Lewis calls it, by the preceding sinus is, however, essentially different, for in the first part a right ventricular pacemaker, and in the second part a left ventricular pacemaker, causes the regularly recurring ectopic beats.

Fig. 12 shows a typical example of parasystole. There is complete auriculo-ventricular dissociation, the auricles beating slightly less frequently than the ventricles. At first the P deflexion precedes R, and then fuses with it. Later P emerges from R, and gradually approaches T, ultimately fusing with it. The next ventricular contraction is prema-

FIG. 11.



At first the heart is responding alternately to normal stimuli and to stimuli arising in the right ventricle, then alternately to stimuli arising in the normal site and in the left ventricle. In lead III. it is responding only to normal stimuli. (J. K. R.)

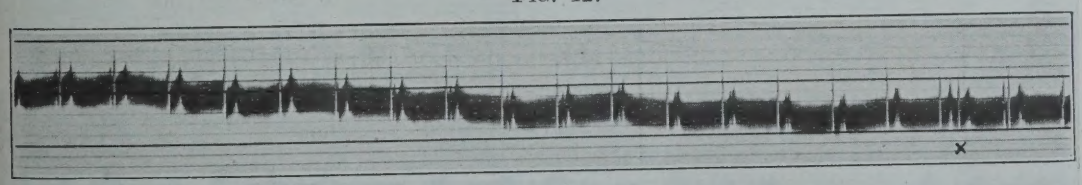
ontraction, whether from variations in the strength r the duration of the stimulus, from variations in the uration of the cardiac diastole, or from variations in ne intracardiac pressure. The most common form of llorrhythmia is a coupled rhythm, due to a regularly curring extrasystole. This is most frequently entricular in origin, though nodal and auricular forms cur. But there is nothing in a coupled rhythm to dicate the ultimate cause of its occurrence. This can nly be elucidated by the investigation of the other rms of allorrhythmia.

In the following examples parasystole seems to ford the most plausible explanation.

In Fig. 11 the ventricle is responding alternately to hysiological stimuli, beats 1–3–5–7, and to abnormal imuli arising in the right ventricle, beats 2–4–6. It seems obable that physiological stimuli are forming regularly at eir usual site all the time, but fail with the alternate ture, though the deflexions are exactly similar to those of the preceding beats. It seems probable that this beat is a response to the preceding auricular contraction, of sinus origin, for the original ventricular rate is quickly resumed. The auricular stimulus has at last reached the ventricle at a time when it was capable of responding, and a contraction ensued.

Parasystole affords an explanation of some bewildering irregularities. In Fig. 13 a ventricular extrasystole is followed by a normal ventricular complex. There succeed three similar extrasystoles, each followed by a normal complex. The rhythm of the extrasystoles is irregular, while that of the normal beats is regular. The next extrasystole occurs somewhat late, and this time without any succeeding normal beat, the sinus contraction failing as it falls due at the time of the extrasystole. The extrasystoles continue till the end of the tracing, never affording the sinus pacemaker a chance of initiating a cardiac contraction. In this

FIG. 12.



The auricles and ventricles are beating independently. When the auricular stimulus occurs at a time when the ventricle is capable of responding to it a premature ventricular contraction occurs (x).

eats to produce a contraction because the extrasystole has ready induced one, for in lead III., when the rhythm is gular, its rate is about double that of the physiological ythm in lead I. Beat 8 is again an extrasystole, but this me arises in the left ventricle. The right ventricular extrastole fails, as it is due to occur a little later (0·08″) ter the physiological beat than the left ventricular contraction, and finds the heart already in contraction and so fractory. Notwithstanding the change in extrasystole, e rhythm of the physiological beats is unaltered, and beat 9 curs punctually. The right ventricular extrasystole, hich is again due, is again supplanted by an extrasystole ising in the left ventricle, and the new pacemaker during e succeeding beats alternates with the normal sinoricular pacemaker, producing a coupled rhythm which is pparently similar to that of the first part of the tracing. It case, owing to a change in rate of the pathological pacemaker, the rôle of the normal pacemaker has been usurped by the pathological one.

If two pacemakers can influence the rhythm of the heart concurrently, it seems probable that three, or even more, may sometimes be attempting to set the pace of the heart. In Fig. 12, as we have shown, three pacemakers are active, and even the most fantastic allorrhythmias may sometimes be explained by a comparable mechanism.

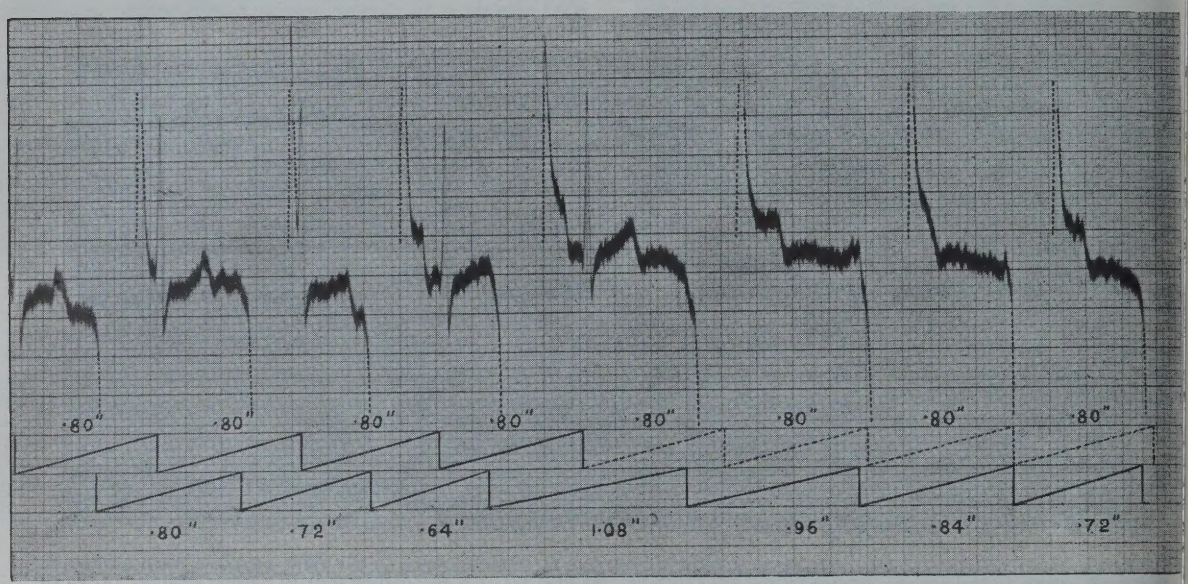
It has been contended that the long continuance of an allorrhythmia, as, for example, in coupled or triple rhythm which may continue for hours or even for days at a time, cannot be explained by parasystole,

because the small variations in the rate of the sinus contractions which so constantly occur would, sooner or later, cause the ectopic stimuli to fall within the period of a normal sinus beat, and so fail to produce a contraction. But if we believe that protective blocking is possible, and that a stimulus may remain "alive" for more than an instant of time, there is a margin during which the ectopic stimulus may produce a contraction. If this margin is exceeded the allorrhythmia ceases, but at other times the margin is sufficient to permit of the allorrhythmia continuing.

Such a condition is illustrated in Fig. 14. In this tracing the sinus rhythm is irregular, and in consequence there are occasions when regularly recurring ventricular stimuli cannot, at their onset, cause extrasystoles as the muscle is refractory. But, if the stimuli remain "alive" for more than a moment, contractions will occur when the muscle is again responsive, but at slightly irregular intervals.

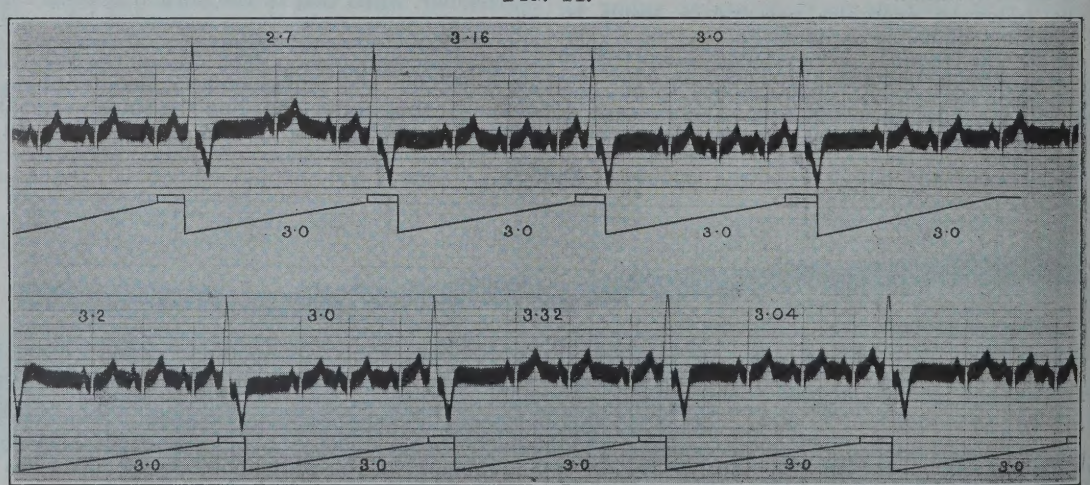
It seems probable that allorrhythmia may arise from several different causes. Glycosuria, dyspnœa, tachycardia, all own several causes, and the same is probably true of allorrhythmia. Re-entry, variations in intracardiac and intrathoracic pressures, nervous phenomena, may all, at times, play their part, but there are occasions when the most satisfactory explanation is that an abnormal pacemaker is interfering with the sinus rhythm. Sometimes the abnormal pacemaker dominates the rhythm completely (paroxysmal tachycardia); sometimes it can only occasionally interfere (extrasystole); sometimes two rhythms, that of the normal and that of an abnormal pacemaker, interplay with each other and we have the heart "serving two masters."

FIG. 13.



At first extrasystoles are followed by normal contractions. Later, owing to change in rate of production of the abnormal stimulus, physiological contractions fail to occur.

FIG. 14.



Sinus stimulus production is irregular, varying from 0·7 to 0·9 seconds. Ventricular stimuli arise regularly at intervals of 3·0 seconds, and each remains alive for 0·4 seconds.

SOME OBSERVATIONS ON THE MORTALITY FROM RHEUMATIC FEVER AND HEART DISEASE IN LONDON.

By MATTHEW YOUNG, M.D. Glasg.,
NATIONAL INSTITUTE FOR MEDICAL RESEARCH.

EVIDENCE has been adduced from the special study of series of cases of acute rheumatism by some observers, including Miller (1925), that the occurrence of this disease in children is closely associated with unfavourable conditions of life, though not apparently with extreme poverty. Benjamin (1927) concluded that rheumatism is a disease of poor people and that the incidence may well be in direct relation to the degree of poverty. Stevenson (1923) has also found that, in adult males, valvular disease of the heart, which in the great majority of cases is a sequel of rheumatic infection, is more fatal in the lower ranks of society. This finding is based on data for the several social groups tabulated by the Registrar-General for the biennium 1901–02. Nevertheless, further information on the relationship between social status with its environmental conditions and rheumatic infection and its sequelæ can be obtained from an investigation of the variations in mortality. The necessary data for the purpose were obtained from the recorded mortality for the metropolitan boroughs of London where it was possible to obtain approximate measures of varying social status with which to correlate the mortality; also to determine whether the association were of a similar degree and kind in the two sexes.

Analysis of Data and Discussion.

Unfortunately it is only possible to obtain an approximate indication of the prevalence of acute rheumatism in the several metropolitan boroughs from the recorded mortality-rate. In the absence of any fairly extensive records of cases (of which there is no prospect in the immediate future), it is difficult to refute as it is to support the view that there is a general parallelism between mortality and prevalence. For lack of any reliable evidence to the contrary it has been assumed that the death-rate does at least provide a rough index of the prevalence of the disease, and the relative incidence of acute rheumatism in the metropolitan boroughs so far as it can be expressed by the standardised mortality-rates in persons at all ages for the decade 1911–20 is shown in Map I. The mortality is heaviest in Deptford, Stepney, Bermondsey, Wandsworth, Hackney, and Bethnal Green, all of which districts, except the last, are adjacent to the river Thames for part of their extent, but the rates are also relatively high in Hampstead, Islington, and Stoke Newington. The lowest mortality-rate occurs in Kensington, where relatively low rates are also found in Chelsea, Westminster, and Woolwich, as well as in St. Pancras and Camberwell. It is interesting to compare this map with that given by Shrubsall (1925), showing the distribution of cases of children suffering from rheumatic heart disease who were attending the L.C.C. special schools in 1925. His map indicates the aggregation of cases in the vicinity of the Thames and along the lines of the alluvial valleys marking the ancient courses of rivers. The comparison shows that, while relatively high death-rates are found in some districts in which there is evidence of concentration of juvenile cases, there does not appear to be any striking coincidence in the two distributions.

If, as is generally supposed, a relatively unfavourable environment is an important predisposing factor in acute rheumatism, and if the mortality from the disease may be accepted as an index of the prevalence, then some indication of the influence of this factor might be expected in those boroughs in which the general social conditions vary considerably. Of the different criteria of varying social status that are available for the metropolitan areas, three have been selected—namely (1) the degree of overcrowding or the proportion of the population living more than two per room; (2) the proportion of domestic servants per 100 private families; and (3) the mean infantile mortality-rate. The correlation coefficients between the standardised mortality-rate from acute rheumatism in the metropolitan areas and these indices of social status are shown in Table I. The standard errors of the coefficients are

TABLE I.—*Showing the Correlations between the Standardised Rheumatic Fever Death-rate (S.D.R.) in Persons at all Ages in the Metropolitan Boroughs of London for the Decade 1911–20 and Various Indices of Social Status.*

Variables.	*r.*	
	Males.	Females.
S.D.R. rheumatic fever and index of overcrowding or proportion of population living more than two per room	0·080±0·188	0·253±0·177
S.D.R. rheumatic fever and mean infantile mortality-rate	0·312±0·171	0·345±0·166
S.D.R. rheumatic fever and proportion of domestic servants per 100 private families	−0·253±0·178	−0·294±0·173

such that little emphasis can be laid on the apparent existence of some slight association between the mortality from acute rheumatism and general exposure to unfavourable conditions of life seen in this table. It seems worthy of note that the proportion of overcrowding seems to be least closely associated with the rheumatic fever mortality-rate. Miller (1927) has come to the conclusion that overcrowding is not a factor of prime importance in the production of the disease in children from the fact that, although rheumatism is a disease of the poor, it is less common in the poorest than in the stratum above them.

Relationship of Rheumatic Fever to Heart Disease.

The relationship of the rheumatic fever mortality to the mortality from heart disease at the several ages in the different areas of London may now be examined. Various observers have tried to assess the proportion of fatal organic heart disease that may be described as primarily due to rheumatic infection. The estimates very considerably, but it has recently been suggested that there is a reasonable basis for the belief that at least half the total recorded mortality from heart disease is rheumatic in origin. In a recent report of the Ministry of Health, Dr. Glover (1927) has come to the conclusion that 40 per cent. is probably a safer figure. In London, in the five years' period 1921–25, 56 per cent. of the recorded mortality from heart disease in all its forms, and 44 per cent. of that registered as valvular disease of the heart, occurred at ages over 65. It is in this later period of life that degenerative or senile changes account for a relatively large proportion of the recorded mortality from heart disease, and it is also at these ages that heart disease is most often stated as a cause of death in an attempt to give a precise diagnosis to a terminal and often indefinite condition.

Although a fairly large proportion of the fatal heart disease in this later period of life is probably of rheumatic origin, the proportion at the earlier ages is undoubtedly considerably greater, and it is important therefore to compare the prevalence of acute rheumatism with the mortality from heart disease at these earlier ages. The index of regional rheumatic prevalence—i.e., the standardised mortality from rheumatic fever—has therefore been correlated with the mortality from heart disease in the separate sexes in certain age-groups for the two periods of years 1911–14 and 1919–25. The correlation coefficients are shown in Table II. For the period 1911–14, a small positive correlation is apparent

between the rheumatic fever death-rate and the death-rate from heart disease at ages under 15 and at ages 15–24, but for the other age-groups the coefficients are negative and insignificant. In females the coefficients are positive, but insignificant at all the ages. For the period 1919–25 the coefficients

TABLE II.—*Showing the Correlations between the Standardised Rheumatic Fever Death-rates in Persons at all Ages in the Metropolitan Boroughs of London for the Decade 1911–20 and the Mortality from Heart Disease at Different Ages in each of the Periods 1911–14 and 1919–25.*

Variables.	*r*.			
	Males.		Females.

15–24 years ..	0·200± 0·181	0·357± 0·165	0·446± 0·151	0·141± 0·185
25–44 „ ..	0·100± 0·187	−0·107± 0·187	0·405± 0·158	0·187± 0·182
45–64 „ ..	0·555± 0·131	−0·256± 0·177	0·264± 0·176	0·083± 0·188
65 years and upwards	0·023± 0·189	−0·258± 0·176	0·193± 0·182	0·028± 0·189
At all ages ..	0·134± 0·186	−0·150± 0·185	0·338± 0·167	0·102± 0·187

for all the age-groups in males and females are positive, except at ages under 15 years in males, but it is only at ages 45–64 in males and at ages 15–24 and 25–44 in females that they are of sufficient magnitude in comparison with their standard errors to indicate that any importance can be attached to them. It seems worthy of remark that the correlation between the rheumatic fever death-rate and the death-rate from heart disease at ages over 65 years is usually smaller than at the earlier ages, although little importance can be attached to this feature. The results in the table thus fail to indicate clearly that the mortality from heart disease at any particular age period is especially associated with the prevalence of rheumatism in the different areas.

Social Status and Heart Disease.

The relationship of social status to the mortality from heart disease at the different ages will now be examined and discussed. Correlation coefficients were calculated for the death-rates in the two periods 1911–14 and 1919–25 and the same three indices of the general level of the social condition of the residents in the metropolitan areas already described. In order to economise space the coefficients are not tabulated, but although certain anomalies occur, the results obtained from the three criteria appear to be in general agreement, and may be stated very briefly. The mortality from heart disease seems to be positively correlated with a relatively unfavourable environment, but the degree of association varies at different ages. At the ages 15–24, 25–44, and 45–64 the correlation is quite definite, varying from 0·5 to 0·8 in all the groups except that relating to the domestic servant index and male mortality, which will be referred to later. There is, however, fairly clear evidence that the mortality at ages exceeding 65 years has, as might be expected, no obvious relation to environmental conditions as measured by any of the criteria adopted. There is also a definite indication that in males the mortality at ages under 15 years in both periods is less closely associated with environmental conditions than is the mortality at the succeeding ages. The coefficients obtained from all three indices and the mortality in females under 15 years in the period 1911–14 suggest a like conclusion, but the coefficients for the period 1919–25 suggest that the association at ages under 15 years is nearly as intensive as at the higher a At the intermediate ages the correlation coeffici for females appear to be, on the whole, higher t the corresponding coefficients in males, but differences do not appear to warrant the conclu that the response to environmental condition more definite in females than in males. It is doub true that the female population is more continuo exposed to unfavourable home conditions, but disadvantage in this respect is probably cou balanced by the greater exposure of members of male sex to strain and unfavourable conditio their occupations. The correlation of the propo of the domestic servants index and the male mort at the different ages does not provide the re series of coefficients shown for the remaining ind but, if the size of the coefficients in this instance not lend much support to the inferences drawn the other indices, the general run of their sign the intermediate ages may be said, at least, nc contradict them. The correlation between the s condition of the areas and the mortality from h disease appears to be practically equivalent at ages 15–24, 25–44, and 45–64, and generally intensive than that between the mortality rheumatic fever and the mortality from heart di at any of the corresponding ages.

In previous papers (Young, 1921 and 1925) writer has shown that the rheumatic fever mort in the county divisions of England and Wal positively correlated with the amount of ra and negatively with the mean temperature—in words, is directly associated with the general preva of damp and cold. In the county areas the am of organic heart disease is also definitely assoc with the amount of rheumatic fever. The divi of the metropolis, however, must be regarde subject to considerably more uniform conditio rainfall and temperature than the different are the country, and consequently it is not surpri that the mortality-rate from rheumatic fever s somewhat less variation in the metropolitan than in the county areas, and that a less de association between it and the incidence of disease appears to be present in the former th the latter.

Conclusions.

Assuming the rheumatic fever mortality-ra be an approximate index of rheumatic preval there is a suggestion that the local incidence o disease has a slight but direct relation to the s status of the metropolitan areas and shows a ge tendency to be more common in the areas wher conditions of life are least favourable. The mort from heart disease at the ages in which the majority of the cases are undoubtedly rheu in origin shows apparently a still closer relatio than the prevalence of rheumatism to those env mental circumstances implied by difference in ge social status. There is a suggestion that the mor from cardiac disease in females is more closely re to environmental conditions than in males, whether this is real or not, and, if real, whether attributable to a more continuous and prol exposure of the female population to delete influences in unhealthy homes, is a question on it is difficult to hazard an opinion.

THE FUNCTIONS OF THE LIVER

AS AFFECTED BY MALARIA INDUCED IN GENERAL PARALYTICS.

By R. G. WILLIAMS, M.R.C.S. Eng.,
PATHOLOGIST TO THE HOSPITAL FOR THE INSANE, CLAREMONT, WESTERN AUSTRALIA; LATE ASSISTANT MEDICAL OFFICER, BEXLEY MENTAL HOSPITAL.

During last year laboratory tests were carried out Bexley Mental Hospital with a view to investiting derangements of hepatic function occurring the course of artificially induced malaria amongst neral paralytics. The vestigations comprised eries of lævulose tolerce curves, van den rgh reactions, and some scellaneous tests. In , 107 lævulose tolerance ves were obtained m patients undergoing larial treatment, and curves from patients h proved or suspected patic derangements to other causes.

esults with Lævulose Tolerance Curves.

he lævulose tolerance ves were obtained in following way:—

fasting blood-sugar imen was taken at ut 9 A.M. and then 40 g. ævulose in 8 oz. of water n by mouth. Bloodar specimens were then ected ½ hour, 1 hour, ours, and 2½ hours after lævulose feed. It was d inconvenient (and ecessary for the determination of a representative curve) ollect a specimen two hours after the feed, though for e of the curves the two-hour specimen was collected.

The analyses were done in the afternoon or evening, and the Folin-Calvert colorimetric method was used throughout.

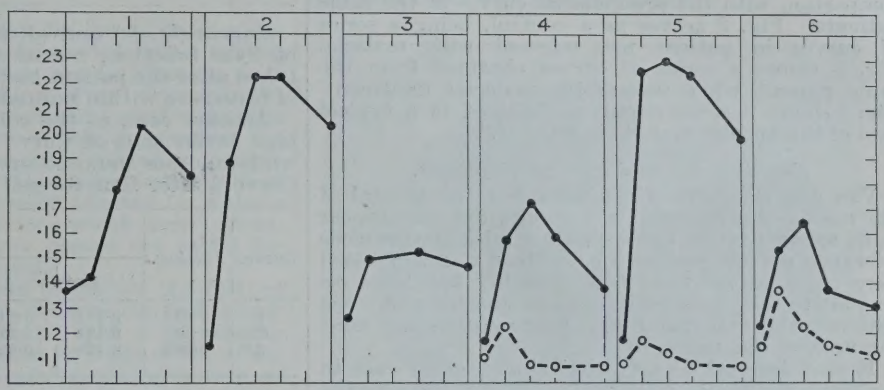
Lævulose tolerance curves were done on patients: (*a*) before inoculation with malaria either by mosquito bite or blood inoculation; (*b*) during the course of the malaria; (*c*) after recovery from malaria; (*d*) during and after malarial relapses; and (*e*) suspected of gross liver disease.

The cases investigated were: (*a*) sixteen general paralytics, who were given malarial treatment; (*b*) one tabetic, who was given malarial treatment; (*c*) four cases of gross liver disease (comprising two of cirrhosis, one of acute yellow atrophy, and one of secondary malignant growths); and (*d*) six general paralytics, who were not given malaria (controls).

In every malarial case before the end of the treatment the curves were of the type indicating some hepatic insufficiency, and in many cases the curves became abnormal after the first or second rigors. In a few cases the curves indicated extreme hepatic insufficiency, and such patients remained critically ill for some days after the malaria was stopped by the administration of quinine. One such case died eight days after the malaria had been stopped. At autopsy there was found (in addition to a terminal broncho-pneumonia) an acute yellow atrophy of the liver. It was the occurrence of this condition in two previous fatal cases which led to the present investigations.

In most cases the curves became normal soon after the malaria had ceased, but in some of the more serious cases of apparent hepatic insufficiency, as demonstrated by the curves, the return to normal was

FIG. 1.



Shows six curves. Nos. 1 and 2 were taken from the same patient, one with severe cirrhosis of the liver; the condition was confirmed at autopsy a few days after the date of the last curve. No. 3 was taken from another case of cirrhosis of the liver, also confirmed at autopsy. Nos. 4, 5, and 6 were from three cases of G.P.I. towards the end of their malarial treatment. No. 4 curve was taken from a patient on the 13th day of the infection after five significant temperatures over 103° F. No. 5 curve was taken from a patient on the 21st day of the infection after ten significant temperatures over 103°. No. 6 curve was taken from a patient on the 17th day of the infection after nine significant temperatures over 103°. The dotted lines are curves taken from patients before commencement of malarial treatment.

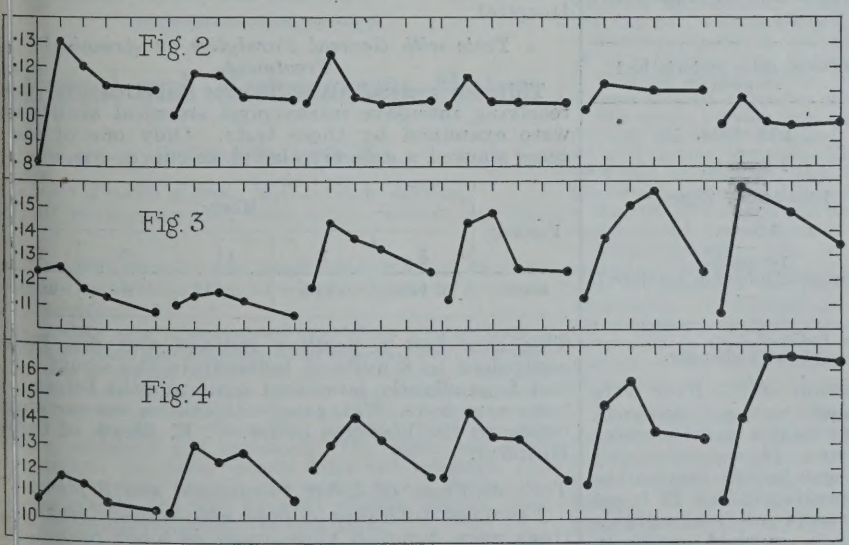


Fig. 2.—Series of curves from a patient who was bitten by malarial mosquitoes after the first curve had been taken, but who did not develop malaria. Curves were taken on the 3rd, 5th, 7th, 9th, 13th, 15th, 20th, 24th, and 34th days after the unsuccessful attempt at infection. It is unnecessary to reproduce more than six of these curves as they show no appreciable variation.

Fig. 3.—Series of curves taken from the same patient three months later. He was again bitten by malarial mosquitoes and curves taken on the 4th, 9th, 18th, 21st, 25th, and 29th days after infection. He developed his first significant temperature on the 15th day and had in all 11 such temperatures. Quinine was given on the 26th day.

Fig. 4.—Series of curves in a typical case taken on the day before infection and then on the 7th, 12th, 17th, 22nd, and 29th days. The patient developed his first significant temperature on the 11th day and in all had eight significant temperatures. Quinine treatment was commenced on the 23rd day.

much slower. In four cases who had relapses some time after their period of treatment, marked hepatic insufficiency was indicated by curves taken during the relapses. The curves obtained from patients with gross liver disease were comparable with those in the malarial series (see curves). The case with secondary carcinomatous deposits in the liver showed a normal curve, there being sufficient liver tissue to deal with 40 g. of lævulose.

It is scarcely necessary to tabulate all the curves obtained in these investigations, as Figs. 1, 2, 3, and 4 are sufficiently representative. Fig. 1 shows the similarity between curves obtained in gross organic disease of the liver (curves 1, 2, and 3) and curves obtained towards the end of malarial treatment (curves 4, 5, and 6). The later curves also allow of comparison with the pre-malarial curves in the same patients. Fig. 2 serves as a control, being a series of curves in patient not infected with malaria. Fig. 3 shows a series of curves obtained from the same patient while undergoing malarial treatment. Fig. 4 shows a series of curves obtained in a typical case of therapeutic malaria in a G.P.I.

Results with van den Bergh Reactions.

Van den Bergh reactions were done on several of the cases. As, however, the results did not appear to be as sensitive as those obtained with the lævulose tolerance curves, and as 5 c.cm. to 8 c.cm. of blood were required for each test (possibly too large an amount to take frequently from an anæmic and toxic patient), the van den Bergh reaction was not done throughout the series.

It is of interest to note that almost every case in the series developed conjunctival icterus towards the end of the malaria, while several of the patients had appreciable jaundice.

In the few cases (three) in which the van den Bergh reaction was done before the inoculation of malaria the reaction was negative. Eight tests were done on patients during their malarial period, and in each case the reaction was either an indirect positive or biphasic one. The biphasic reaction was present in those patients who had appreciable jaundice.

Dr. R. Armstrong, of Bexley Mental Hospital, kindly undertook to do some van den Bergh reactions on general paralytics undergoing malarial treatment, with the following interesting results :—

Patient.	Before inoc.	After 3 rigors.	One week after malaria had stopped.
A	Di.	—	—
	I.	2·5 units.	1·75 units.
B	Di.	—	—
	I.	3·5 units.	2·5 units.
C	Di.	—	—
	I.	4·5 units.	Died after 5 rigors.*
D	Di.	—	—
	I.	2·5 units.	1 unit.
E	Di.	—	—
	I.	4 units.	1·5 units.
F	Di.	—	No malarial infection developed.
	I.	—	—

Di. = Direct; I. = Indirect.
* The liver and kidneys showed fatty changes.

Tests for the antitoxic function of the liver were carried out, but satisfactory results were not obtained. Sodium salicylate was given by mouth and the urine then examined for conjugated glycuronates by Tollen's method. The failure was largely due to the difficulty of obtaining representative (24 or 12 hour) specimens of urine from the patients and from suitable controls. Urobilin was found in marked excess in the urine of most of the patients while they were having malarial treatment. This test, however, was not done systematically, and the exact numbers have not been recorded.

Tests on General Paralytics Treated with Therapeutic Relapsing Fever.

In addition to these investigations similar tests have subsequently been carried out on seven general paralytics who were given relapsing fever for therapeutic purposes. (The patients were injected with emulsions of blood containing the spirochæte of West African relapsing fever, *Spiroschaudinia duttoni*. In none of these cases did the curves indicate marked hepatic defect. One case was followed throughout his treatment and the following curves were obtained:

—	Fasting.	Hours.				
		½	1	1½	2	2½
(*a*)	0·107	0·113	0·101	0·101	—	0·096
(*b*)	0·104	0·135	0·127	0·124	—	0·108
(*c*)	0·102	0·138	0·134	0·117	—	0·113
(*d*)	0·105	0·134	0·122	0·109	—	0·093
(*e*)	0·101	0·124	0·123	0·113	—	0·103
(*f*)	0·096	0·119	0·118	0·101	—	0·095

Curves (*b*), (*c*) and (*d*) indicate slight impairment of liver function, but the later curves (*e*) and (*f*) taken after the patient had had three prolonged spells of fever, are within normal limits.

Another case, at the conclusion of four periods of high fever, showed Curve 1 in the following table, while another showed Curve 2 after three fevers and Curve 3 after four fevers.

Curve.	Fasting.	Hours.				
		½	1	1½	2	2½
1	0·088	0·115	0·112	0·105	—	0·09
2	0·103	0·116	0·119	0·120	—	0·10
3	0·109	0·120	0·122	0·119	—	0·10

These curves, if they show any defect at all, show it to be incomparably less than was found in the malarial patients.

Three of the relapsing fever cases showed, at some time in their treatment, very faintly positive indirect van den Bergh reactions. Tests in the other cases were entirely negative. Urobilin and urobilinogen were not found in pathological excess in any of the urines examined.

It was possible to perform these tests through the kindness of Dr. F. L. Golla, and the medical superintendent and Dr. W. A. Caldwell, of Banstead Mental Hospital.

Tests with General Paralytics on Arsenical Treatment.

Thirteen general paralytics or tabetics who were receiving intensive intravenous arsenical medication were examined by these tests. Only one of the cases showed a defective lævulose curve—viz. :—

Fasting.	Hours.				
	½	1	1½	2	2½
0·108	0·140	0·142	0·135	—	0·115

This case had a positive indirect van den Bergh equivalent to 8 units of bilirubin in the serum. He had been slightly jaundiced some months before the tests were done. This case, with others, was examined owing to the kindness of Dr. V. E. Lloyd, of Guy's Hospital.

Tests on Cases of Lobar Pneumonia and Septicæmia.

Lævulose tolerance curves and urinary examinations were done on three cases of lobar pneumonia and one severe septicæmia. From the pneumonia cases almost normal curves A, B, and C were obtained, as shown in the table below.

The septicæmic case upon whom two curves were done was critically ill for three weeks; she had many rigors each day, and eventually died. Permission for an autopsy was refused. Her curves are given below, D and E. They show marked liver defect. Urobilin and urobilinogen were present in pathological excess in the urine only in the septicæmic case.

hese cases were examined through the kindness of
ie medical superintendent and Dr. Norcliffe Roberts,
St. Giles's Hospital, Camberwell.

—	Fasting.	Hours.			
		½	1	1½	2½
5th day of pyrexia .	0·104	0·134	0·117	0·115	0·107
9th day of pyrexia .	0·111	0·128	0·123	0·117	0·112
Day after crisis .	0·096	0·127	0·125	0·107	0·103
—	0·100	0·142	0·136	0·133	0·123
—	0·111	0·139	0·156	0·143	0·133

Conclusions.

The conclusions which may be drawn from these vestigations are: (1) Lævulose tolerance curves, pecially when done in series, are satisfactory tests detecting and estimating liver derangement. (2) The van den Bergh reaction and tests for urobilin d urobilinogen in the urine help to confirm the ults obtained from lævulose tolerance curves. (3) The tests reported in this paper indicate that liver is much more severely affected in malaria n it is in the other conditions which were investiged. (4) Lævulose tolerance curves are useful for ntrolling therapeutic malaria.

No attempt has been made to discuss the history the lævulose tolerance test, because the test is now well established as to make such a proceeding te unnecessary. No mention is made of the effect the malaria upon the patients' mental condition, as h observations would be beyond the scope of this mmunication. The malaria used was a pure benign tian strain obtained from Colonel S. P. James's oratory at Horton Mental Hospital.

My thanks are due to the medical superintendent permission to publish these results, to Dr. John nder for his advice and assistance, to the assistant dical officers of Bexley Mental Hospital for permission to examine their cases, to Messrs. Lawford, ith, and Cliffe for their help in the collection of ecimens, and to Dr. F. L. Golla and Captain S. A. an for their advice and guidance.

Clinical and Laboratory Notes.

A CASE OF ASTHMA.

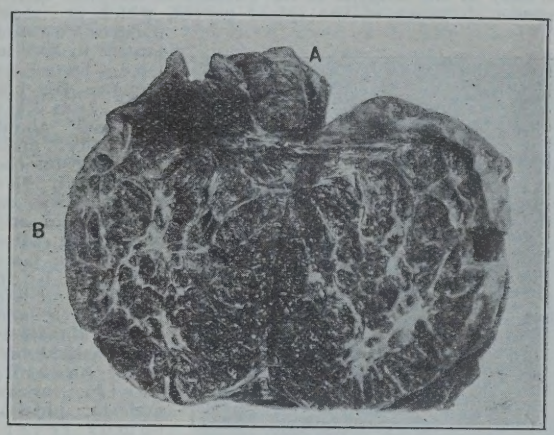
By DAVID PERK, M.B., CH.B. LEEDS,
ASSISTANT MEDICAL OFFICER, WEST RIDING MENTAL HOSPITAL.

ASTHMATIC attacks are associated with a number morbid conditions, two of which coexist in the case described.

he patient was admitted to the West Riding Mental pital 26 years ago suffering from insanity with epilepsy, became physically feebler and more and more demented advance in years. Her history was uneventful until months before her death, at the age of 65, when one night had an attack of "asthma," during which she was edly dyspnœic and cyanosed. Her pulse was weak irregular; her heart sounds faint and irregular, and e was a systolic bruit in the mitral area. During the wing months she had frequent similar attacks, each k lasting intermittently for two days.

st mortem, in addition to marked pathological changes he heart, the entire left lobe of the thyroid was found e replaced by a tumour which must have exerted derable pressure on the larynx and trachea during life. heart weighed 180 g., and was much contracted. The ce was wrinkled, and the coronary arteries were very ious. There were atrophic changes in the left ventricle uced by an extreme degree of mitral stenosis. The y was greatly diminished, the papillary muscles were shrunken, the mitral valves were united to form a nhole orifice which led into a funnel, formed by the n of the upper ends of the chordæ tendineæ. Microscopically, the muscle-fibres were shrunken, and contained an excessive amount of yellowish granular pigment.

The thyroid tumour extended from the laryngeal prominence to the upper border of the manubrium sterni and clavicle. It pressed against the lateral surface of the larynx and upper rings of the trachea, arching them towards the right side, and almost occluding the lumen, so that this portion of larynx and trachea was distorted into the shape of a scimitar. The common carotid artery was arched outwards by the tumour, which measured 3½ in. by 2¼ in., and weighed, when shelled from its fibro-muscular capsule, 130 g. It was roughly spherical and crudely and irregularly lobulated, with a smooth, shiny surface of sea-blue tint, interrupted in places by blood-vessels and white connective tissue bands. It contained a core of calcified fibrous tissue and some gelatinous fluid which coagulated very readily. Minute jelly-like particles, which dissolved on pressure, were suspended in the fluid. They were of a mucinoid nature, and stained well with Bismarck-brown.



A.—Solid portion of tumour; complex adenoma.
B.—Cystic portion of tumour; cystic adenoma.

The cut surface shows that the tumour is composed of two portions, a cystic and a solid portion. The roughly spherical solid lobule had no connexion with the rest of the tumour, and was merely enclosed by a continuation of the capsule surrounding the latter; on section it had a faintly whorled appearance. Embedded in its surface, beneath the capsule, were some plaques of calcareous material.

Microscopically, it resembled a complex adenoma, part of it exhibiting the features of a fœtal type, and part of it those of an adult type of adenoma. The fibrous tissue stroma showed extensive calcareous deposition.

The cystic portion was traversed by glistening strands of fibrous tissue of irregular widths and directions, which divided it into numerous loculi filled with a multi-coloured jelly-like substance. The fibrous network was in many places calcareous, and in a pocket of the capsule there was a deposit of heterotopic bone, in the shape of an incisor tooth, about half an inch in length.

Microscopically, the loculi which contained colloid material were lined by a single layer of cubical epithelium, with a tendency to proliferate freely. This caused a duplication or multiplication of the lining layer, and in many places a heaping up of the cells, some of which were embryonic or degenerate in type, ovoid or flattened. Stained sections of the tooth-shaped structure showed the presence of lacunæ and canaliculi arranged in Haversian systems.

It would appear, therefore, that the "asthma" may have been either (*a*) an expression of failure of cardiac compensation, as is strongly suggested by the post-mortem findings in the heart, supported by the history of cyanosis and cardiac irregularity accompanying the paroxysms of dyspnœa, and a systolic mitral bruit; or (*b*) a pressure-symptom of the thyroid tumour. Severe pressure on the larynx and trachea, or on the recurrent laryngeal nerve, might have produced the attacks of dyspnœa and cyanosis, while pressure on the vagus nerve would explain the irregularity of the heart associated with the attacks.

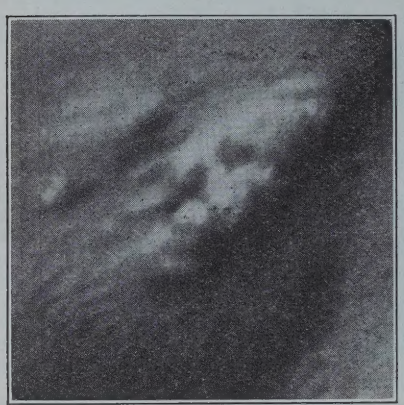
My thanks are due to Prof. M. J. Stewart for his kind advice, and to Dr. S. Edgerley, the medical superintendent, for permission to publish the notes.

TWO CASES OF NEURINOMA.

BY J. HARGREAVES ROBINSON, L.A.H. DUB., L.M.R.C.P. IREL.,
HON. SURGEON, ROYAL MATERNITY CHARITY, LONDON.

THE two cases here described fall into that heterogeneous group of conditions known as "neurinomata." The first one is a typical example of neurofibromatosis as described by von Recklinghausen; the second had a neoplasm, suggesting the condition called by Mott "pachydermatocele."

CASE 1.—A man, aged 31, noticed at the age of 17 two small nodular swellings in the course of the intermediate cutaneous nerve sheath. Three years later he noticed more swellings. He now has many neurinomata scattered profusely in the sheaths of the cutaneous branches of the posterior divisions of the spinal nerves, which are most numerous and largest in size in the lumbar region. He has 465 moles scattered about the body, most prevalent on the arms, in the axillæ, and on the scrotum and chest. He states that he has always been healthy, and is a non-smoker and total abstainer. His medical history records benign tertian malaria, phlebotomus fever, and an *Entamœba histolytica* infection. The patellar reflex is ±++ slightly more marked on one side than on the other. His fingers are tremulous, and muscular fibrillation of a facial muscle was noticed during examination. There are slight alterations in epicritic and protopathic sensibility. Mentally he could not be classed as a typical normal individual, but would be described by the alienist as of the mattoid type. He admits, after an obvious mental effort, that what he describes as "night starts" occur just at the moment when he is falling to sleep. He gives the impression of making a special effort to answer a simple question.



Inguinal swelling in Case 2.

CASE 2.—A healthy young man first noticed during the year 1919 a swelling on the lower part of the abdomen. He states that it has very slowly progressed in size, and has never been painful, even on pressure, but that friction against the clothing has been rather uncomfortable. He has never noticed any other swellings anywhere on his body, and does not know of any other member of his family having had anything of the kind. During conversation he gives the impression that attention and conation are rather more marked than usual, and he speaks rather slowly. On the lower surface of the abdomen there is a large, sessile, cutaneous neoplasm, slightly pendulous, and freely movable on the aponeurosis, excepting at a small area towards the inner border where movement is not so free. The neoplasm is firm in texture, insensitive to pressure, and clinically suggestive of the pachydermatocele of Mott. The inguinal lymphatic glands are normal in size. There is a wide band of discoloration of the skin in the middle line extending from the ensiform cartilage to the pubes. No other swellings can be discovered; 53 small moles are scattered about the body. Nerve sheaths are not palpable. I removed the growth, and it has been described as follows: "The large mass of tissue is composed of very cellular fibrous tissue, with little tendency to a whorled arrangement in most places. There are, however, areas in which the cells form small concentrically laminated masses. No epithelium is seen covering this mass. The structure appears to be that of neurofibromatosis."

Both cases are doubtless lesions of the endoneural connective tissue, and the association of multiple moles, pigmentation of the skin, and neurofibromatosis as described by Soldau are evident.

A CASE OF INTRACRANIAL NEOPLASM WITH UNUSUALLY RAPID DEVELOPMENT OF SYMPTOM

BY JOHN INKSTER, M.D. ABERD., M.R.C.P. LOND., D.P.H. OXF.,
HON. CONSULTING PHYSICIAN, STOCKTON AND THORNABY HOSPITAL; HON. PHYSICIAN, NORTH ORMESBY HOSPITAL, MIDDLESBROUGH.

THE following case is of interest in that rapidity development of symptoms led to an error of diagnos

The patient, a man aged 38, had nasal polypi removed July 7th, and during the operation pus was found in bo antra. The antra were drained, and he was discharged fr hospital apparently well. He should have reported hospital on the 16th, but was unable to do so, as he w suffering from septic tonsillitis. A week later, havi recovered, he presented himself for examination, and t condition of the nose and throat was satisfactory. remained well until August 13th, when he noticed that had difficulty in playing the piano with the right ha The difficulty increased, and power was completely l in the right upper extremity. Two days later he noti that he was dragging the right foot, and power was l in the right lower extremity. On the following day he h involuntary movements of the upper and lower extremiti although he had no power of voluntary movement. Th movements were so severe that they interfered with sle and his friends were unable to hold the arm and leg st He had had no headache, but had vomited once.

When seen on August 20th he had complete paraly of the right upper extremity, almost complete paraly of the right lower extremity, and slight weakness of the ri side of the face. The pupils were equal, and reacted norma to light and accommodation. There was no nystagm and the eye movements were normal. Examination of fundi showed neither optic neuritis nor any other abn mality. He was unable to close the right eye complet On the right side the triceps, supinator, and knee- and ank jerks were all exaggerated, and there was ankle-clon The plantar reflex was extensor on the right side and fle on the left. Sensation was slightly blunted in the ri arm and leg. Speech and mental condition were unaffect There was no incontinence and no retention of urine.

The heart, lungs, and abdomen, except for an old appen ectomy scar, showed no abnormality. The urine normal. Pulse-rate was 72, and temperature was 98·4°. A diagnosis of intracranial abscess was made, and he admitted to North Ormesby Hospital. A blood co showed 10,000 white cells per c.mm., and a normal differen count. It was thought that the position of the abscess just subcortical under the middle of the motor area, an skiagram showed an indefinite shadow in this region. Th was no development of symptoms nor of physical si except that he vomited twice.

On August 31st Mr. J. B. T. Keswick trephined c the middle of the motor area on the left side, and explo the underlying brain, but no pus was found. The oper in the skull was enlarged and the surrounding brain explo but without success. There was practically no cha until Sept. 4th, when respiration began to fail. Pat became cyanosed, and there were râles over the whol both lungs. The temperature rose to 100·6° F. and pulse-rate to 148, and he died on Sept. 6th.

Post-mortem examination showed no meningitis, and brain appeared normal on external examination, ex that there was hæmorrhagic discoloration of its sur under the opening in the skull. Section revealed a la soft, chocolate-coloured tumour in the left cerebral he sphere. It was irregularly fusiform in shape, with its l axis parallel to that of the cerebral hemisphere, and widest part in the region of the Rolandic area. It exten for about an inch and a half forward, and for abou inches backward from this area. It lay mostly in the w matter, but extended into the grey matter of the co in the middle of the motor area. It was not encapsula Unfortunately, as a report was required for a coror inquest, the brain had to be cut without being harde and so accurate observation of the relationships of tumour could not be made. Histological examina showed the tumour to be a gliosarcoma. There was fibrous adhesion of the visceral to the parietal pleura the greater part of the right lung, and there was conges of the bases of both lungs. The cæcum was adherent to anterior abdominal wall by fine fibrous adhesions where appendix had been removed 20 years previously. There no pus in the ethmoidal cells. All other organs were heal

Commentary.

In this case the onset was not sudden enough the lesion to be embolism or hæmorrhage, and th

as no evidence of circulatory failure to suggest rombosis. At the same time the development of ie paralysis seemed too rapid to be caused by a oplasm. The history of a recent operation for a ptic nasal condition followed by septic tonsillitis as strongly suggestive of a metastatic abscess. ie occurrence of what from the description appeared be Jacksonian convulsions suggested that the sion was in contact with the cortex, but the extent the paralysis prepared one for a deep lesion in the ternal capsule. The rapidity of onset and the history recent nasal sepsis were misleading, but the cksonian convulsions led to the localisation of, any rate, a part of the lesion.

It is of interest that optic neuritis and headache ere absent and that vomiting was infrequent, in ite of the large size of the tumour. Perhaps this explained by there being little, if any, increase in e intracranial pressure. The brain when removed d not appear larger than normal, nor did the left le seem larger than the right.

I am indebted to Dr. W. H. Mackinlay for the ivilege of seeing this case, and to my colleague, c. Keswick, for undertaking the operation.

Medical Societies.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING of this Society was held at Liverpool on t. 28th, Prof. FLETCHER SHAW (Manchester), the esident, in the chair, when Mr. ST. GEORGE WILSON iverpool) read a paper on

Twilight Sleep.

e said that he had investigated twilight sleep opolamine narcosis) on the lines recommended by e committee appointed by the Section of Obstetrics d Gynæcology of the Royal Society of Medicine in 17. He had treated a series of 32 cases (16 primiparæ d 16 multiparæ). He considered his results under e following headings :—

Precautions taken to Exclude Sensory Impulses.—A iet room was selected which could be darkened. tton-wool soaked in oil was placed in the patient's rs. She was kept in bed and discouraged from king, and conversation was carried on in whispers. bservations were made, and the delivery carried out, the light of a small shaded lamp.

Time of Injections, Drugs Employed, and Doses.—primiparæ injections were begun when the cervix s dilated to the size of two fingers and in multiparæ en labour had definitely commenced. The first ection consisted of omnopon, gr. 2/3 (Roche) and opolamine hydrobromide, gr. 1/50 (Burroughs llcome). Each subsequent injection consisted of opolamine, gr. 1/450. In no case was the omnopon peated. The second and third injections were given hourly intervals. Subsequent injections were given longer intervals, from 1½ to 2 hours, according to e condition of the patient. If labour ceased entirely, it did in four cases, the injections were withheld til it recommenced. The average number of ections in primiparæ was 4·5 and in multiparæ 4. The injection of pituitary extract was employed 17 cases (9 primiparæ and 8 multiparæ), chiefly in e second stage to augment the expulsive contractions the uterus. The amount of pituitary extract for a gle injection never exceeded 0·25 c.cm.

Duration of Labour.—The average duration of bour was as follows :—

—	Primiparæ.	Multiparæ.
tal length of labour ..	14 hrs. 45 mins.	16 hrs. 26 mins.
ration of labour after treatment began	5 hrs. 41 mins.	6 hrs. 5 mins.

The longer period in multiparæ was explained by the exceptional length of some of the labours.

Effect on Uterine Contractions.—In all but two cases the uterine action was altered by the injections. Lengthening of the intervals between the contractions was the chief alteration. The strength and duration of individual contractions were also diminished. These changes were most marked between the second and third injections—i.e., in the second hour—and could be ascribed to the action of the omnopon, for in most of the cases the pains increased again in force and frequency to culminate in expulsion of the fœtus. In four cases labour ceased altogether during the treatment for periods of 18, 6, 4, and 2 hours respectively.

Voluntary expulsive efforts did not arise automatically, but as a rule the patient made voluntary expulsive efforts when instructed to do so.

The maternal pulse and respirations were unaltered. Observations on the *blood pressure* during labour did not show any relation between the height of the blood pressure in mm. of mercury and the character and frequency of the uterine contractions. As a rule it was noted that the blood pressure tended to fall during labour.

Subjective Symptoms.—Thirst was noticed in every case. Nausea occurred in a few cases. Some of the patients complained bitterly of the pain, especially in the second stage.

Objective Symptoms.—Sleep between the pains was present in every case; slight restlessness and a moderate amount of mental confusion were noted as being associated with the uterine contractions in the most successful cases. Marked restlessness, difficult to control and tending to occur in periods of uterine relaxation, was an indication for postponing the next dose of scopolamine. Uncontrollable excitement was never seen.

Condition of Reflexes.—The pupils were normal and reacted to light. The corneal reflex was also normal.

Memory of Objects Shown.—A key or a pair of scissors was usually the object shown to the patient for the memory test. The memory of the object was lost in only two cases, but recognition of the object shown was never at fault.

General anæsthesia was only induced in five cases at the end of the second stage—three times for forceps extraction and twice because it was feared amnesia had been lost owing to the interval over which injections had been stopped when labour had ceased.

Mode of Delivery.—Delivery of the child was spontaneous in all but four cases, when forceps were used. Forceps were employed in two multiparæ with contracted pelvic outlet, and in two primiparæ, one with twins and the other with poor pains and a rigid perineum. In the latter cases analgesia was so good that an anæsthetic was unnecessary.

Delivery of Placenta.—In one case the placenta was delivered by Credé's manœuvre. In nine cases it was noted that hæmorrhage associated with the third stage was more than usual, but never excessive.

Condition of the Child.—One child was stillborn. The mother, a primipara, had premature rupture of the membranes and weak pains. The other children were born alive and were discharged healthy. In the majority of cases the child showed varying degrees of apnœa, but cried sooner or later on being left alone in a warm place. All the babies were thirsty for the first 24 hours.

Sleep after delivery was encouraged, and it was found that the better the sleep the more successful was the case.

Amnesia and Analgesia.—The establishment of amnesia alone was attempted as the condition of analgesia signified too great an intoxication. "Islands of memory" were produced by stimuli being apperceived during a lessening of the amnesia. The memory test was valueless, however applied. The best guide was the condition of the patient between the pains and her reaction to uterine contractions. The optimal condition was that of somnolence between the pains, with a moderate degree of restlessness and muttering delirium associated with the uterine

contractions. There were three main groups of cases: 1. Seventeen in which the patient remembered nothing of the labour. 2. Twelve in which the patient had islands of memory formed and remembered incidents during the labour. 3. Three in which amnesia failed.

Puerperium.—The condition of the patient was markedly better than in normal cases. There was less exhaustion. Three cases of pyrexia occurred—one of pyuria, one of suppuration of the perineum, and one of retention of membrane and delayed involution of the uterus. Lactation was normal in all the cases. Mr. Wilson's *conclusions* were:

(1) The treatment is very good for the mother, lessening the mental and physical strain of labour; but it exacts unremitting attention from both doctor and nurse. (2) The uterine action is definitely diminished, and so labour tends to be longer. This may be counteracted, however, by the use of pressor substances or by artificial methods of delivery. (3) There is no danger either to mother or child if the effects of the injections are carefully observed. (4) The memory test is useless. (5) Strict precautions must be taken to exclude all adventitious stimuli.

The PRESIDENT said that twilight sleep had been much boomed when it was introduced 20 years ago. It had then fallen into disrepute, and now was the time to take a clear and dispassionate view. He did not make use of it to any great extent. The great disadvantage was the amount of time taken up.

Dr. F. H. LACEY (Manchester) asked if Mr. Wilson had noticed an abnormal number of persistent occipito-posterior presentations. He thought that the apnœa was due to delivery rather soon after the injection of morphia. He used ether at the end of the second stage to diminish the pains; it also tended to stimulate the infant. He agreed that pituitrin was needed to stimulate uterine contractions. He gave scopolamine, gr. 1/100, for the first dose, and gr. 1/200 subsequently. A good nurse was essential and attention to the bladder was necessary.

Prof. MILES PHILLIPS (Sheffield) asked if the patients complained of dryness of the mouth. The preparation of scopolamine used was, he said, of importance.

Mr. WILSON, in reply, said that he had not had any persistent occipito-posterior positions in this series. He did not consider it was true twilight sleep if an anæsthetic was used. He had not had any patients who remembered their thirst during the labour.

Inversion of the Uterus.

Mr. WILSON showed a specimen as follows:—

A 3-gravida, aged 30, was delivered of a healthy male child with the breech presenting. Twenty minutes afterwards compression of the uterus was employed for bleeding, when the whole uterus and part of the vagina became inverted. The placenta was almost separated. It was removed and the fundus uteri was douched with hot lotion till it retracted. A tentative attempt at a reposition failed, and the patient was treated with morphine, gr. ¼, salines, and warmth for moderate shock. She died three hours later.

The specimen consisted of the pelvis with the uterus and the vagina inverted, showing the broad and infundibulo-pelvic ligaments greatly stretched and the ovaries and tubes out of sight in the cavity of the inverted uterus. There was no intraperitoneal bleeding and the bottom of the pouch of Douglas was markedly raised.

Dr. LACEY described a second case of inversion:—

A primipara, aged 23, was admitted to hospital suffering from an acute inversion which had occurred ten hours previously after an apparently normal labour. The midwife had expressed the placenta and had then noticed the inverted uterus. The patient was profoundly shocked. After treatment of the shock some hours later an attempt at reduction was made, but failed owing to œdema. Aveling's repositor was tried and failed. The patient had pyrexia for three months and had a white-leg. She suffered from menorrhagia and was in very bad health. Nine months later she was better; an attempt was made at replacing the uterus by incising the cervix and anterior wall of the uterus. This failed, until sutures were put in the fundus of the uterus and were pulled up through an abdominal incision. Then the uterus was easily replaced and the patient made a good recovery.

Prof. PHILLIPS said that of 184 cases collected fro THE LANCET and the *British Medical Journal* up 1912, 43 (23·4 per cent.) had been fatal. Seventee of the patients had died without treatment of a kind, usually before the doctor's arrival. In 49 cas the condition had been left unreduced (oft undiagnosed). Of these two (4 per cent.) died sepsis. In two cases the body of uterus had be twisted off and torn away by midwife. Both patie recovered.

With immediate replacement the figures were follows:—

	Cases.	Deaths.	Per ce
Marked shock	79	24	30
No shock	23	0	0
Shock not mentioned (probably absent)	11	0	0

In one case replacement had been deliberat postponed until the shock had passed off. The pati recovered.

Of 34 cases recorded in the same journals betwe 1912 and 1926 four had proved fatal, one them before the doctor's arrival. In seven the c dition had been left unreduced (some undiagnose All of these recovered. The following was mortality when immediate replacement was p formed:—

	Cases.	Deaths.	Per c
Marked shock	8	3	37
No shock	9	0	0
Shock not mentioned	3	0	0

In seven cases replacement had been deliberat postponed until recovery from shock. Among th there had been no deaths. He was of opinion t treatment of shock was essential before any atte at reposition.

Miss FRANCES IVENS (Liverpool) said that she seen a patient who had suffered from inversion tw

The PRESIDENT said that he had seen three ca in one of which inversion had been followed puerperal sepsis and later by death due to intest obstruction caused by adhesion of a loop of intes to the fundus of the uterus.

In reply Mr. WILSON and Dr. LACEY said that t thought the cause of shock was stretching peritoneum, possibly with compression of the ova in the inverted uterus. The treatment in the place was that of shock.

Mr. W. W. KING (Sheffield) described a case o

Concealed Accidental Hæmorrhage Treated Expectan

The patient, aged 46, was eight months pregnant her twelfth child. Fourteen hours before admissio hospital she suffered from faintness, repeated vomiting, acute abdominal pains. On admission she was extremel the face was pallid, the mouth and tongue dry, and respirations short, jerky, and rapid. The pulse uncountable at the wrist, was 180 at the apex. There a cloud of albumin in the urine. The uterus was tense, and tender. She was a hopeless surgical risk. She given 500 c.cm. of defibrinated blood and 2·0 c.cm thromboplastin, and the blood pressure soon afterw was 100 mm. of mercury. Two hours later the b pressure was 80, and she was given another blood t fusion, after which the blood pressure rose to and rema at 100. Labour then started, and she was delivered in hours of twins with two pounds of blood-clot. There no post-partum hæmorrhage and recovery was uninterru

In a recent paper before the Society, said Ki King, he had called attention to the fact tha concealed accidental hæmorrhage the uterine mu showed no histological evidence of disease or degen tion, and that it was functionally active and cap of strong contractions. This case supported the of the activity of the uterine muscle and showed the expectant method of treatment was possib cases of concealed accidental hæmorrhage.

Prof. E. E. GLYNN (Liverpool) asked if the bl platelets had been counted in this case. He found that they increased in number after confine up to the eighth to tenth day.

Dr. J. H. WILLETT said that he believed treatment should be expectant, though he had Cæsarean section in one or two cases.

Mr. KING, in reply, said that the blood-platelets had ot been counted. Mr. King also showed a specimen f carcinoma of the cervix in a case in which radium ad four years previously been inserted for the eatment of bleeding from a fibroid.

Dr. LEITH MURRAY (Liverpool) described a case of

Columnar and Squamous Carcinoma coexisting in a Uterus.

The patient was a nullipara, aged 53, in whom the enopause had occurred 18 months previously. For four onths she had had a foul blood-stained discharge. The erus was enlarged and there was a nodule on the cervix lieved to be a small retention cyst. A total hysterectomy as done four and a half years ago. She had had four eatments with radium with no recurrence. The specimen owed two different types of growth: (1) a fungating owth in the corpus; and (2) a dense infiltration tending from the external os upwards for two and a lf inches. Above was a columnar carcinoma typical of at in the body, while lower down was the usual uamous-celled carcinoma with massive processes of uamous cells surrounded by considerable round-celled posit.

The nodule on the vaginal cervix, said Dr. Murray, as obviously an area of squamous carcinoma not t broken down. He also described a case of rcinoma of the cervix occurring five years after noval of the appendages, and showed sections of the dometrium and ovary after intra-uterine radiation. Dr. C. P. BRENTNALL (Manchester) showed a ecimen of Oxyuris Vermicularis in the Uterus, and r. LEYLAND ROBINSON (Liverpool) showed specimens ating to suspected criminal abortion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

A MEETING of this Section was held on Nov. 4th, en Dr. GIBBON FITZGIBBON, the President, opened liscussion on

SOME POINTS IN OBSTETRICS WHICH CALL FOR RECONSIDERATION.

began by referring to the increased frequency h which Cæsarean section was performed for ntracted pelvis, without corresponding reduction in number of craniotomies and difficult forceps diveries, and without any considerable improvement the mortality of the mothers and infants. He ocated strongly the development of antenatal nics and reviewed the various conditions of ectant mothers which could be benefited by enatal supervision.

Dr. L. CASSIDY considered that Cæsarean section he treatment of contracted pelvis must be regarded a failure of obstetrics. The number of women o required the operation at term was comparatively all. He thought that if medical men understood importance of very carefully investigating every nan at the 36th week of pregnancy the mortality m Cæsarean section would be reduced almost to ishing-point. Properly carried out the operation uld involve very little risk to the patient. per cent. of all women had the head unfixed at the et of labour, and yet a fairly large percentage of m had a perfectly normal labour. Every woman whom the fœtal head could not be forced into the vis at the 36th week should be examined under sthesia.

Dr. BETHEL SOLOMONS said that he had greatly eased the scope of antenatal work at the Rotunda. thought that doctors in private practice should rge a composite fee for attendance, in order to ourage patients to come regularly, and for panel ients antenatal supervision should be paid for should be compulsory. The incidence of Cæsarean ion had increased and the operation had been sed. No self-respecting obstetrician would do ion if it could be avoided. In spite of every effort number of cases at the Rotunda had increased, but the operation was nearly always done after a trial of labour, and the lower segment was the site of choice. When done at the proper time in selected cases it was an excellent operation, but the time must be carefully chosen, and the operator must make up his mind from a careful study of the case that the child would not be delivered by the natural passages, and the child should not be left so long that it was dead or potentially dead before section was started. The low segment operation could not be regarded as a failure in obstetrics, and when it was employed after careful antenatal supervision and a thorough trial of labour, combined with pelvimetry, and the mother and child were saved, the result might be regarded as good obstetrics. Every patient should have the advantage of internal pelvimetry besides other methods of diagnosis.

Sir WILLIAM SMYLY felt certain that the number of cases of Cæsarean section would go on increasing. The operation was not done often enough in cases of placenta prævia; in Germany it was now frequently done in cases of eclampsia. Timidity often led men to perform operations because they were afraid to wait and see. He had had patients who had been in hard labour for a week and had delivered themselves at the end of that time, perhaps of a dead child. Women would not consent to Cæsarean section more than a few times; in fact most women would not face it a second time. The question, How long should labour be tried, resolved itself into a matter of experience. The head would remain above the brim till the cervix was retracted. Not many obstetricians would nowadays wait longer than three or four days if the cervix was not drawn up by then. This he did not call a trial of labour. It was experience, more than any definite thing which happened, which indicated how long labour should last. The head was the best pelvimeter, but not the only one.

Dr. J. S. QUIN had known cases in which Cæsarean section had not been done because doctors were inclined to think that it was not an obstetrical operation, but a surgical one. Cæsarean section was a way of getting out of a difficult situation, and though he agreed that all obstetricians wanted to avoid doing it unnecessarily, he thought that it had not been used enough in the odd peculiar cases which cropped up every now and again. The results obtained from Cæsarean section were poor and not on a par with the results of any other major operation in surgery for a non-malignant condition. The maternal mortality was large and there was at least 50 per cent. sterility after the operation.

Dr. A. H. DAVIDSON said that antenatal work was the most important advance which had been made in obstetrics within recent years. He would like to see the need for it demonstrated to all the practitioners and all the women in Ireland. Its greatest use was that it brought a large number of women with abnormal pregnancies into hospital. Detroit had many antenatal clinics, run by the city itself, but with easy access to the hospitals. The maternal mortality of cases delivered in the city, and not in the clinic, was 6·75 per 1000, whilst the mortality in the clinic was only 3·5. The deaths from puerperal sepsis had been reduced by over one-half at the clinics, but the mortality from eclampsia had only been reduced by 25 per cent. Of the women who attended the clinics 30 per cent. were found to have some intercurrent disease or abnormality, which could usually be set right. Only 6 per cent. of the women of Detroit, however, came to the clinics. Dr. Davidson believed that antenatal care should be carried on into postnatal care, and that every woman on leaving hospital should be advised to come back in six weeks' time to have a bimanual examination made to find out where the uterus was, and should be told to bring the baby back with her.

Dr. A. P. BARRY had found that, practically speaking, the urine of every pregnant woman contained albumin. He thought that the only way to arrive at a conclusion about albuminuria was to get a catheter specimen.

Dr. D. J. CANNON asked if, after trial of labour, the President did a lower segment section or a classical segment section.

Dr. R. H. CORBET thought that the chief obstacle to antenatal care was the inertia of the public. Antenatal work needed an earlier start; it was impossible to get good results unless the patients came for advice early, and followed the advice given to them. The increase of Cæsarean section was partly due, he considered, to the increased transport facilities, and was to that extent fictitious. The same argument applied to eclampsia.

The PRESIDENT, in reply, said that he did not want to be taken as condemning operative midwifery in the hospitals; but he thought that the cases should diminish, and they were not diminishing. Any patients who showed abnormality at antenatal clinics should be put under special care. Seven or eight hours' trial of labour was sometimes long enough, but sometimes was not. After trial of labour he at present favoured lower segment section, though at one time he had done classical segment section. Obstetrical cases should be watched throughout. In England not one of the maternity hospitals went in for internal pelvimetry.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.

ON Nov. 1st Prof. D. P. D. WILKIE read a paper on *Gall-bladder Disease and Gall-stones.*

After tracing the history of the development of gall-bladder surgery, Prof. Wilkie described the types of gall-stones which were at present believed to be of metabolic origin—namely, the single radiate cholesterol stone, found as a rule in stout females, and associated with afebrile attacks of colic but with little disturbance of health, and the multiple pigmented calculi found most typically in acholuric jaundice. He considered that cholecystitis was almost invariably an intramural streptococcal infection. It was quite exceptional to be able to grow organisms from the bile in any but acute cases. The failure of most observers, in this and other countries, to confirm Rosenow's observations was due, he believed, to faulty technique. Dr. A. L. Wilkie, working in the Surgical Research Department in Edinburgh, had shown that in 85 per cent. of cases of chronic cholecystitis a streptococcus could be grown from the cystic gland, and this organism on experimental inoculation had shown a selective affinity for the gall-bladder. Prof. Wilkie went on to describe the mode of origin of the multiple cholesterol-bilirubin-calcium stones after an attack of acute cholecystitis, and the origin of the multiple mulberry cholesterol calculi following cholesterosis with lipoid papillomata. In discussing the symptomatology of gall-stone disease, he drew special attention (1) to obstruction of the neck of the gall-bladder as the most frequent cause of gall-stone colic; (2) to the fact that the common bile-duct had no muscular coat, which permitted a stone to reside there without giving rise to symptoms; and (3) to the definite muscular contraction of the gall-bladder which might be produced by ingestion of fat. In diagnosis he ascribed a very limited field of usefulness to the duodenal tube; although it gave valuable information in late cases where the ducts were infected, it failed to give positive evidence in the earlier stages when the infection was intramural. Of all accessory methods in the clinical diagnosis of gall-bladder disease he gave first place to cholecystography, demonstrating the accuracy with which radiolucent cholesterol calculi could be made out, and the advantages of combining cholecystography with a barium meal examination. In regard to treatment, he contended that drugs which merely had a disinfectant action in the lumina of the biliary passages could not be expected to achieve much. He advocated removal of the gall-bladder, in whose wall the infection was located in every case in which it could be done without undue risk.

Reviews and Notices of Books

REFLEXES.

Conditioned Reflexes: An Investigation of t Physiological Activity of the Cerebral Cortex. I. P. PAVLOV, For.Mem.R.S., Director of Physi logical Laboratories in the Russian Academy Sciences, Petrograd. Translated and edited G. V. ANREP, M.D., D.Sc., Lecturer in Physiolo in the University of Cambridge. Londo Humphrey Milford, Oxford University Pre 1927. Pp. 430. 28*s.*

THE work accomplished by Prof. Pavlov and h numerous collaborators in the course of the la 25 years has been known to many physiologists, a its application to functional problems connected wi the nervous system of man has been attempted more than one occasion—somewhat tentatively, it true, and on a comparatively small scale. We e probably safe in stating, however, that except in few circles it has not been appreciated at its f value, largely because of the absence of any more less complete and authoritative exposition of bearings in a language with which most workers a familiar. In 1924 Prof. Pavlov conducted a cou of lectures dealing with the results he had obtain and with his technique and working theories, a from these lectures the present volume has be elaborated. Here are spread out before the rea not merely protocols of numberless experiments a descriptions of complicated technical procedure; he is now enabled for the first time to follow t train of thought in the author's mind, step by st from initial investigations whose import was scarc realised even by their originator, to a stage wh their significant range is shown by abundant a conclusive evidence to have expanded beyond t narrow bounds of laboratory vision and to touch w unmistakable definiteness not a few of the deep problems of cerebral function.

A historical introduction deals with the limitati of ordinary clinical and pathological methods solving questions of cerebral localisation and fu tions, and with the futility, in Prof. Pavlov's opini of subjective modes of inquiry. In place of t latter, by long and laborious trials, he eventua brought to a high pitch of perfection the method approach by what in his terminology is the "c ditioned reflex." Briefly, while inborn reflexes are in number, an experimental animal (the dog) can shown to have *in potentia* a capacity for develop very many other reactions, equally definite, obj tive, and automatic—equally reflex, in short—wh can be initiated and perpetuated by excitations o which the experimenter has full control. When f is shown to the animal and salivary secretion beg in a few seconds we are dealing with an inbo reflex; when food is put in his mouth, or acid, sal is secreted, either for alimentary reasons—an inb alimentary reflex, or to wash out a rejectable s stance—an inborn defence reflex. By combining giving or showing of food with a stimulus of anot order—e.g., the ticking of a metronome—a phy logical association can be started and developed the animal, the result of which can easily be de mined. Within a comparatively short time and wh comparatively few repetitions it is possible to get animal to react by salivation when only the sou of the metronome reaches him, all other excitati being absent. This is the conditioned reflex. On simple an experimental basis Prof. Pavlov has b up a body of physiological doctrine whose wi reaching applications it is the purpose of this fasci ing volume to discuss, but they can be underst only if the extremely complex development of research is systematically followed. By elabor experimentation it has been possible to exam physiologically the functions of external and inte inhibition, to demonstrate irradiation and concen tion as physiological properties of the cortex,

tudy the analytic and the synthetic function of the ame—in a word, to show how the cortex actually orks, and all this, be it repeated, by means which xclude the subjective factor absolutely.

Reference must be made to Prof. Pavlov's con-lusions that sleep is nothing else physiologically an internal inhibition, which has diffused itself ver the whole cortex and descended also to some fracortical centres (posture and equilibrium centres Magnus and De Kleijn); and that if the inhibition confined to the cortex a state of catalepsy ensues. he behaviour of the animal is determined by the nited function of the cortex; by its cortical analysers" (sensory centres) it adjusts itself to its rroundings; without its cortex it is converted into comparatively simple reflex machine, with a rela-vely limited number of conditioned reflexes; coördi-ation of its activities is based on the innumerable nditioned reflexes for which intermediation of ie cortex is indispensable. One of the fundamental eculiarities of cortical life is its perpetual state of ix, its extraordinary reactivity; for the cortex the me intimately interwoven functions of excitation id inhibition are for ever at work, as are seen in ie spinal cord when it is experimentally isolated. a final chapter the author attempts a comparison ith what is known of human activity, and states e obvious conclusion, that "different kinds of bits based on training, education and discipline of y sort are nothing but a long chain of conditioned flexes."

The full import of this epoch-making addition to urophysiological doctrine, and through it to neuro-gy, can scarcely yet be grasped. It is possibly the tstanding contribution of the present century.

Les réflexes de posture élémentaires : étude physio-clinique. By P. DELMAS-MARSALET, Préparateur de Physiologie, Faculty of Medicine, Bordeaux University. With an introduction by Prof. V. PACHON and H. VERGER. Paris: Masson et Cie. 1927. Pp. 115. Fr.16.

BY elementary reflexes of posture Dr. Delmas-arsalet understands what is commonly called a flex shortening contraction. Known for many years the "paradoxical contraction" of Westphal, oduced in the tibialis anticus, for example, by dden and firm approximation of its origin and sertion points, the phenomenon has been studied many workers and in different forms of nervous ease, as well as in states of health. Although a l examination of its behaviour in extrapyramidal nditions was published by Foerster in 1921, and hough it was critically considered by Wilson in s Croonian lectures of 1925, dealing with the same oblems, the author makes no reference to these ntributions, but ascribes our "notion of the reflex posture" to Foix and Thevenard (1923). Whether e familiar shortening contraction should be called reflex of posture is open to question; be this as it ay, the merit of Dr. Delmas-Marsalet is to have bjected it to a careful and minute investigation a variety of nervous conditions. His view that it highly characteristic of extrapyramidal disease will t receive the assent of all neurologists, since its quency in these states has not always been con-med; whether the exaggeration of "reflexes of sture" *explains* the characters of Parkinsonian idity, as is here contended, is equally open to dis-ssion. Interesting experiments with different armacological agents lead to the conclusion that mentary reflexes of posture appear to correspond, *la vie de relation*, to vagotonia in the *vie végétative*. ey are stated not to be influenced either by de-rebration or by experimental lesions of the basal nglia, whence it is concluded that Parkinsonian ndromes are not attributable to defect of function these (cortical, basal) centres—surely a dubious e of argument. Indeed, the author considers that rrent views of Parkinsonian pathogenesis are iated by the "fundamental error" of supposing that localised lesions of basal grey matter are more important from the viewpoint of function than cortical lesions "minimes, mais trés étendues." Here without question a finger is laid on the weak point of the clinico-anatomical method, but whether his own alternative theory is therefore or thereby justified is another matter.

L'état actuel de l'étude des réflexes. By M. MINKOWSKI, Professor in the University of Munich. Translated from the German by Dr. HENRI EY, Interne des Asiles de la Seine. Paris: Masson et Cie. 1927. Pp. 75. Fr.12.

A RECENT monograph by Prof. M. Minkowski has been translated into smooth and accurate French by Dr. H. Ey, and will doubtless receive due appreciation in this form. It deals with the whole question, so much in the melting-pot, of reflexes. With the view that definition cannot be established with certainty or satisfaction we are entirely in agreement; the simplicity of the Sherringtonian conception lands us in difficulties when it is applied to particular phenomena. To attempt its delimitation by stating that reflexes are "reactions which are neither too complex nor too simple" is merely to avoid the problem. There is a world of difference between the non-neural or aneural response of a lowly organism and a complex conditioned reflex in man, yet it is equally true to say that no break of a fundamental kind is traceable in the scale reaching from one extreme to the other. Another contention of the author which cannot be too persistently maintained is that the conditions of natural life in the animal differ materially from those of experimental and even of clinical exploration. Isolation of mechanisms by experiment distorts our idea of integrated function to a very great extent, and the application of knowledge thus derived to the behaviour of the organism as a whole must be undertaken with no little circumspection. In other words, what we often suppose to be concrete and specific functions, experimentally determined, are in reality but fragments of functions artificially elicited and isolated from their natural connexions.

Prof. Minkowski's contribution deals largely with the organisation and the dissolution of reflexes and with their relation to instincts, and is conceived throughout in a scholarly and philosophic vein which gives the whole problem its appropriate setting. In regard to the question of instincts he enrols himself with those who hold them to be distinguishable solely by their greater complexity and range, conditioning the activity not of one organ but of the individual as a whole. The fact that both serve to bring about reactions objectively useful in a biological sense (for the organism concerned, or for the species) proves their fundamental identity.

ATLAS OF BONE RADIOGRAPHY.

Atlas de radiographie osseuse. By G. HORET and A. DARIAUX, Radiologists to Les Hôpitaux de Paris, and Prof. JEAN QUENCE. Paris: Masson et Cie. 1927. Pp. 129. Fr.160.

THERE has recently been somewhat of an epidemic of radiological atlases published in this country. This volume, however, claims to be the first of its type in France. It deals with normal bones and joints only, and forms the first of a series of X ray atlases in course of publication. Further volumes will deal with pathological bone conditions, the stomach and duodenum, the intestine, the urinary tract, and the development of the osseous system. Each of the 123 illustrations is accompanied by an outlined duplicate which is annotated in the margin, and the following data are supplied: (1) the position of the part radiographed; (2) the angle of the normal ray to a definite anatomical point or plane; (3) the distance from the anticathode; (4) the degree of reduction, if any; (5) full anatomical explanation of all the shadows seen. The radiograms are well chosen and

well reproduced, and the method of outlining adopted makes the explanatory text clear. The radiological anatomy of the skull is especially well portrayed and the interpretation of the overlapping shadows easy to follow. The authors point out the value of a knowledge of radiological anatomy to students in the dissecting rooms, and put in a plea that it shall be taught along with the "dry" osteology—a course which is now adopted in at least three British medical schools.

This atlas forms a useful reference for those who wish for a copy of the normal to compare with any pathological condition, and is a great help in acquiring a knowledge of the normal. It is one of the best of its type, and we shall look forward to the subsequent volumes of the series.

HYGIENE IN INDUSTRY.

A Short Manual of Industrial Hygiene. By L. P. LOCKHART. With foreword by Lord INVERNAIRN. London: John Murray. 1927. With diagrams. Pp. 114. 3*s.* 6*d.*

Dr. Lockhart has written in simple language a little book which cannot fail to interest works managers and foremen in the principles underlying health. The spirit in which the facts are set out should go far to recommend them to all who realise that the health of workers is an economic asset without which in these days profits are hard to come by. The author states the principles of factory hygiene in relation to ventilation, humidity, and illumination, dealing sympathetically with the need for cloak-rooms, washing facilities, and canteens. But he makes it clear that without personal hygiene the provision of hygienic accommodation will fail of its effect, and the way is pointed for maintaining daily health and avoiding such diseases as the common cold and influenza. Vague ill-health, he points out, is at the root of most sickness; what is the matter with the sick is their tendency to be sick. Industrial accidents are but seldom "acts of God," they are commonly the result of the human factor in industry. Illness or fatigue breeds errors of judgment and carelessness which are fundamental causes of accidents. Useful hints are given for first-aid in emergencies. A chapter is properly devoted to the characteristics of the young workers from whom industry derives its strength or weakness; every effort to settle them well into their work and to keep them well when so engaged will be money and time well spent. The net value of establishing medical supervision for those industrially employed can only be properly assessed by those who are fully occupied in this work of whom the author is one.

The book can be unhesitatingly recommended.

THE QUEST OF THE BOY.

A Study of the Psychology of Character Training. By F. W. W. GRIFFIN, M.A., M.D., Assistant County Commissioner (London) Boy Scouts; late Lieutenant, Southwark Regiment Church Lads' Brigade. London: The Faith Press. 1927. Pp. 148. 1*s.* 6*d.*

PARENTS of old trained character with a light conscience and a heavy hand. Now we seek to cultivate it more tenderly. Dr. Griffin goes to work with reverence in his study of boyhood along the lines of the Hindu Trinity. His first three chapters deal with Wisdom, or "the right use of knowledge," and he discusses the training of the senses by a multitude of games and tests and their control for use by memory, association, logic, and concentration. Six chapters deal with Power—the instincts, the emotions, and the stages of growth and adaptation. The last three chapters treat of Will, or conscience made manifest in conduct, and especially in citizenship and social service. Many of the aphorisms will be useful to teachers in all circumstances, though they are written by the author in connexion with the boy scout movement. Here are three particularly valuable warnings for pedagogues:—

"The leader who tries to transfer his ideals to a boy is wasting the time of two people."

"Boys are frequently told that 'they are in honour bound to,' &c., but who bound them? Very often someone other than the boy. This is servitude, not honour, which is essential to the character of a free man. A boy may have bound himself one day, and his fluid nature unbinds him the next; what, then, is left to spur him to keep faith? His respect for himself as a fount of honour. Therefore a boy must have self-respect before he can be honourable."

"The man who has lost his boyish horizon altogether is like a long-sighted person who cannot see objects near to hand."

Dr. Griffin discusses scouts of all ages and the way to make them benefit by training. He especially cares for the adolescent or "rover," and to him the last and perhaps the best chapters of a sound book are devoted. He quotes neither Jung nor Freud, nor names them in the bibliography; but he is a well-read and skilled psychologist, who loves wisely the subject of his care.

MANAGEMENT AND ADMINISTRATION OF ESTATES OF LUNACY.

Second edition. By G. E. MILLS, O.B.E., and A. H. RONALD W. POYSER, B.A. London: Butterworths. 1927. Pp. 60. 7*s.* 6*d.*

MEDICAL practitioners are professionally more interested in other aspects of lunacy law than in the management of the property of persons who are of unsound mind or who are incapable—through mental infirmity arising from disease or age—of managing their affairs. But for those who require information on this subject this is a concise and adequate guide. It contains references to medical evidence, including a form of affidavit by a medical attendant.

Reports and Analytical Records.

(1) ATOCIN; (2) ATOCIN WITH ASPIRIN.

(CAVENDISH CHEMICAL CORP., LTD., 137, REGENT STREET, LONDON, W. 1.)

1. Atocin is indicated for the treatment of rheumatism, gout, and lumbago. Whilst the introduction of salicylates was a notable step forward in combating the painful afflictions caused by the different forms of rheumatism, it left untouched many aspects of this malady. In recent years attention has been given to phenylcinchoninic acid and its derivatives—among which is atocin—and the clinical results obtained appear to be hopeful.

When analysed these tablets were found to contain a substance which possessed the properties of phenylcinchoninic acid with starch as an excipient. Each tablet weighs 9·38 gr., of which amount 7·5 gr. is atocin.

2. *Atocin with Aspirin.*—These tablets are used for the same purpose as atocin. When examined they were found to be compounded of 5 gr. of atocin, 2½ gr. of aspirin (acetyl salicylic acid), starch being used as an excipient. Free salicylic acid was absent.

ASPRO.

(ASPRO LIMITED, SLOUGH, BUCKS.)

Aspro is an acetyl salicylic acid preparation advocated for the treatment of headache, sleeplessness, neuritis, neuralgia, and feverishness. On analysis the following results were obtained:—

Weight of each tablet	6·1 grains.
Acetyl salicylic acid	79·0 per cent.
Starch	21·0 „
Ash	0·2 „

The tablets are well made, uniform in composition, and give no reaction for free salicylic acid.

THE LANCET.

LONDON, SATURDAY, NOVEMBER 19, 1927.

PROSTATIC OBSTRUCTION.

We publish in consecutive issues two papers dealing with prostatic obstruction. Last week Mr. DAVID DAVIES and Mr. F. McG. LOUGHNANE analysed a series of cases of suprapubic prostatectomy, and this week we reproduce the text of a Bradshaw lecture in which Sir CUTHBERT WALLACE reviews the progress of our knowledge and treatment during the last 40 years. Whilst operative technique has considerably advanced, he confesses that information about prostatic function and the pathology of enlargement is still very scanty. He favours the view—probably the prevailing one at present—that enlargement is due to the formation of multiple adenomata. If this is accepted, however, it remains a matter of controversy whether the adenomata appear in the prostate itself or in the submucous periurethral glands lying between the prostate and the urethra. It was in 1905 that MOTZ and PÉRÉARNAU first made the suggestion that "prostatic enlargement" is a misnomer and that the periurethral glands, and not the prostate, are really the site of the adenomatous growths. The investigations of Mr. DAVIES and Mr. LOUGHNANE lend some support to this theory, although the number of cases recorded is too small to give any great weight to their conclusions. They found that reappearance of prostatic tissue is the rule rather than the exception after suprapubic prostatectomy, and occasionally this reappearance is followed by a recurrence of symptoms, though this happens rarely.

Of the underlying causes of enlargement nothing is known, and Mr. DAVIES and Mr. LOUGHNANE merely revive a discarded theory when they point out that a past history of gonorrhœa was common in their series. Their view that gonorrhœa has some definite influence in precipitating hypertrophy does not agree with that of other observers; Mr. KENNETH WALKER, for instance, in his Hunterian lecture of 1922, went into the subject at some length, and among other arguments quoted experiences in Japan, where prostatic enlargement is almost unknown, despite the fact that gonorrhœa is common. It must, indeed, be admitted that so far we do not know what it is that makes the prostate enlarge in some men but not in others, and we are equally in the dark when it comes to finding an explanation of some of the sequelæ. As the Bradshaw lecturer points out, "the mechanism whereby the loss of efficiency of the kidneys is brought about is still unsolved." In most cases—even those in which there is a good deal of residual urine—the ureter has to work against only a very small pressure, and there is little to support the view, so commonly held, that inefficiency of the kidneys following prostatic obstruction is a result of back-pressure.

In reviewing the surgery of prostatic enlargement Sir CUTHBERT WALLACE discusses the advantages and disadvantages of the suprapubic and the perineal routes, and like most British surgeons shows a preference for the former. As regards technique he sees no great advantage in substituting an open operation for the older method of removing the prostate by the aid of tactile sensation alone. In this he is in agreement with Mr. DAVIES and Mr. LOUGHNANE, who argue that it is unjustifiable to prolong a severe operation in order to dissect away tags of mucous membrane and fragments of gland tissue, since post-operative obstruction can be dealt with by diathermy. All three writers, therefore, favour a simple rapid operation rather than the open method, with its elaborate toilets of the prostatic bed, whose advantages have been often urged of late years. Indeed, Sir CUTHBERT WALLACE seems to believe that an elaborate operative technique, followed by irrigation intended to reduce sepsis, actually increases the risk of secondary hæmorrhage. These conservative views must, however, be considered in the light of his admission that in his own hospital the mortality has not materially fallen during the last ten years; surgeons have become more chary of performing the one-stage operation, but at St. Thomas's this has only meant that deaths formerly recorded under "prostatectomy" are now found under the heading of "cystostomy." His own view is that hospital statistics can at present be improved only by getting patients to seek earlier help, and he believes that future advances are less likely to come from improvement in technique than from earlier diagnosis and prompter treatment. Whilst agreeing with him about the importance of these factors we find it difficult to believe that progress may not also be achieved through better knowledge of renal function, improvement in our measures against hæmorrhage, and reduction of sepsis, which is here of such importance. The death-rate from prostatectomy is lamentably high, and the fact that patients put off their application for treatment until their condition is dangerous must not discourage fresh attempts to improve technique and to find new ways of guarding against accidents that add so much to the danger of convalescence.

THE NOTIFICATION OF TUBERCULOSIS.

Two purposes are served by the notification of an infectious disease. The first concerns the interest of the patient, the second that of the community. Delay in notification not only deprives the patient of the timely treatment upon which his recovery may depend, but also exposes his neighbours to unnecessary risk. No one questions these facts when the acute infectious diseases are concerned. Any laxity in the notification of small-pox is treated with the utmost rigour of the law. A doctor who fails to recognise diphtheria may need all the support that prejudice can supply if he is to escape a public censure. But when the notification of tuberculosis is in question no such concern is manifested. Though the patient's chance of recovery may depend upon early treatment and though the members of his household may be exposed to grave risks through their ignorance of the danger to which they are exposed, notification is neglected until it is too late to be effective either to stem disease or to prevent its spread. It is shocking that Dr. F. N. KAY MENZIES, medical officer of health to the London County Council, should have to report that 46 per cent. of the patients who died in the metropolitan boroughs in 1926 had either not been notified or had only been notified within three months of death. Dr. W. B. KNOBEL dealt with another aspect of the same question when, in addressing the Glasgow Conference[1] last year, he pointed out that 75 per cent.

[1] THE LANCET, 1926, ii., 90. Transactions of the National Association for the Prevention of Tuberculosis, July 1st–3rd, 1926. London: Geo. Pulman and Sons. P. 59.

of the patients admitted to the King George V. and Pinewood Sanatoriums were in a more or less advanced and irremediable stage of the disease when they first came under effective treatment

Consideration of the problem thus presented involves not only the doctor, but also the patient and the disease. The virulent types of "consumption," to which adolescence is prone, spread with such rapidity that frequently within a few weeks of the onset of the first symptoms large areas of both lungs may be involved. The chronic fibrotic type of the disease so frequently met with in the middle-aged has a far more insidious onset, is frequently masked by bronchitis and emphysema, and is not seldom unrecognised by either patient or doctor until a hæmoptysis or constant decline in weight arouses suspicion of some grave trouble. Nor is the doctor always responsible for delay in diagnosis. The dread of consumption, like the dread of cancer, often leads a patient to conceal his symptoms. The visit to the surgery is postponed because he fears a diagnosis of tuberculosis as a sentence of death. A pathetic anxiety to minimise symptoms, to deny cough, to explain that a hæmorrhage was only slight and obviously had its origin in the throat is characteristic of this type of consumptive. In striking contrast is the tendency of some who love to haunt dispensary waiting rooms—the woman of poor circumstances and in middle life, or the army pensioner in whose sputum tubercle bacilli have never been found. These magnify every symptom that can suggest a diagnosis of pulmonary tubercle and fear to lose their title to special consideration and sympathy among their fellows. It must be admitted, however, that when every allowance has been made the general practitioner is not free from responsibility for many of the delays in notification that are associated with tragic results. "Cough," says Dr. KNOBEL, "is a very common symptom and the symptomatic treatment of it must become almost automatic." Though time and skill are necessary for the diagnosis of early tuberculosis, a measure of common sense should prevent gross errors. A cough that persists for more than a fortnight and is accompanied by expectoration demands careful investigation in a patient of any age. A cough, however slight, accompanied by symptoms of lassitude or by loss of weight should obviously be regarded as a danger signal. The public laboratory is always available for the examination of sputum. The services of the tuberculosis dispensary are at the disposal of every practitioner. When these services are neglected the excuse that a crowded surgery does not permit of scrupulous care in the examination of every patient complaining of chest symptoms is not valid.

English law demands a verdict of guilty or not guilty. Scottish law provides a third alternative; unfortunately the Ministry of Health follows the practice of the English law. What should be the attitude of the practitioner who has taken all reasonable steps to arrive at a diagnosis and who yet remains in doubt? A diagnosis of pulmonary tuberculosis may deprive a patient of his chance of earning a livelihood and may plunge a whole household into despair. If made without sufficient evidence irreparable harm may result. Again, delay in diagnosis till the evidence is beyond dispute may jeopardise the patient's chances of recovery. A solution of the difficulty might be found in the provision of convalescent home treatment. This should be available as part of the antituberculosis scheme of every local authority. The convalescent home should provide treatment similar to that given at a sanatorium for early cases. If the superintendent were a tuberculosis officer of wide experience and if he were provided with means for the complete investigation of every case admitted for observation and treatment he would have little difficulty in deciding whether a patient might safely return home at the end of a few weeks or whether notification and transfer to a sanatorium should be arranged. Some useful experience is available. Five years ago the Ministry of Pensions allotted 200 observation beds for a closely similar purpose—namely, to determine the presence and activity of tuberculous disease in relation to previous military service. In a series of 500 cases observed at Orpington Hospital [2] there were 206 admitted with the provisional diagnosis of pulmonary tubercle in whom tubercle bacilli had never previously been found. In 75 of these the diagnosis was altered to some other chronic bronchial affection. In just one-third of the total cases no clear evidence of tubercle was found. In coming to a decision reliance was placed chiefly on clinical evidence.

RADIOLOGY AND RADIOGRAPHY.

THE amalgamation of the Rontgen Society and the British Institute of Radiology took place formally on Thursday (yesterday), when Sir HUMPHRY ROLLESTON, President of the Institute, delivered an address to celebrate its incorporation with the Rontgen Society and in his opening words paid an eloquent tribute to the late Sir ARCHIBALD REID. It was to REID'S energy and no less to his personality and tact that the Institute owes its present home, and Sir HUMPHRY ROLLESTON'S hope that REID'S portrait might be placed in the museum or the hall of the Institute will be endorsed by all who preserve a memory of that inspiring personality.

The formation of a Radiological Institute was first suggested by the late DEANE BUTCHER some 20 years ago, and 10 years later was revived by a committee presided over by MACKENZIE DAVIDSON with Dr. ROBERT KNOX as secretary. The movement was heartily endorsed by the leaders of the Rontgen Society, and was then taken in hand by REID and other leaders in medical radiology. The main part of Sir HUMPHRY ROLLESTON'S interesting address was devoted to setting out the aims and scope of the institute which he summed up as follows: "It is to serve as a meeting place of all interested in the subject—medical men of every department, radiologists, physicists, technicians or radiographers, instrument makers and manufacturers, so as to form a centre for consultation and coördination, and as a bureau to supply information of all kinds at the service of provincial, overseas, and foreign colleagues as well as of those in the metropolis, and thus to have an international influence." These are large functions, but when we contemplate, in terms of medicine only, what a centre of radiology must now imply, it will be seen that the objects of such a centre have not been unduly multiplied. The introduction of X rays as a means of physical diagnosis in itself constituted an advance comparable with that due to the assistance of the microscope in pathological anatomy, while, though much remains to be ascertained about the therapeutic uses of radiation, not a year goes by without the addition of facts to our store of observations. And these observations are all the more

[2] A. Sandison and G. B. Price: An Account of Tuberculosis Observation Work, THE LANCET, 1924, i., 1195.

valuable because they are derived from the work of men in no sense engaged upon medical research as their prime interest. While medical applications of radiology are most important to our profession, its bearing on arts and sciences and industry generally, as well as on physics and biology in the widest sense, demonstrates the urgent need for the frequent association in team-work of scientific investigators along many lines. This point was made eloquently by Sir HUMPHRY ROLLESTON, who pointed out that in medicine the clinicians, pathologists, anatomists, physiologists, and biochemists have much to learn from radiologists, who in their turn will reap great advantage from close coöperation with colleagues and from an insight into kindred researches such as can be derived from common study and common sources of information. Hence the reference library, which was started by Lady MACKENZIE DAVIDSON'S generosity, and in memory of her distinguished husband, will be an important feature in the new centre, while reminding future workers in this special field of DAVIDSON'S position as an early leader in radiology, already recognised in the Mackenzie Davidson Memorial Lectures under the Rontgen Society and the Electro-Therapeutic Section of the Royal Society of Medicine. Equally essential to the development of radiology will be a museum containing a collection of radiographic films and lantern slides illustrating completely the normal and morbid anatomy and physiology of the human body. The Rontgen Society, now amalgamated with the Institute, was founded as far back as 1897, little more than one year after Rontgen's public announcement of his discovery, although for some time previously he had been engaged upon elaborate investigations in physics upon which that discovery was based. The union of the two bodies has been attendant, for this reason or that, upon long negotiations, but each will gain by the amalgamation.

The affiliation of the Society of Radiographers makes the Institute representative of the technical side of radiology and the difficulty of professional association with persons not appearing on the Medical Register has been surmounted. This Society was incorporated in 1920 with a view to giving a definite professional status to certificated non-medical assistants working in X ray and electro-therapeutic departments. With the formation of the Society an end was put to the confusion between the terms "radiologist" and "radiographer," the former term being reserved for members of the medical profession undertaking diagnosis and treatment by X rays and radium, the latter term designating their trained, but non-medical, assistants. As all know, the training of the radiographer is now a complex and elaborate affair, and their inclusion as equal members of a great amalgamation is right, and incidentally is a sign of the more liberal atmosphere in which scientific therapeutics are conducted to-day.

WOOLWICH AND GREENWICH HOSPITALS.—The Duke of York, who was accompanied by the Duchess, recently opened the first section of the Woolwich and District War Memorial Hospital at Shooter's Hill. The section, which stands in 13 acres of grounds, 400 feet above sea-level, has cost £215,000, will hold 112 patients. There are wards of 26 beds each, a maternity unit of six beds, and isolation beds; sunlight and electro-therapeutic departments have also been provided. Two other sections will be required for the completion of the scheme, which will provide a total of 344 beds. In the Memorial Hall, panelled with various coloured marbles, is kept a Book of Remembrance to preserve the names of 6230 local residents who lost their lives during the war.—Princess Mary has recently opened the new nurses' home erected by the Greenwich Board of Guardians in connexion with the Greenwich and Deptford Hospital. The home will house 130 nurses, and stands so high that it commands views of Westminster Abbey and St. Paul's Cathedral. There are large recreation rooms, and tennis lawns are being laid out.—The Miller General Hospital for South London is being extended at a cost of £38,000, and King Edward's Fund has promised to contribute £16,000 contingently upon the raising of the rest of the money.

Annotations.

"Ne quid nimis."

THE MAUDSLEY HOSPITAL.

THE enterprise and vision of the founders of the Maudsley Hospital have borne ample fruit, and mental hospital officers all over the country now watch its development with great interest. The third report covers the period Feb. 1st, 1925, to Dec. 31st, 1926, and reviews the financial situation for the first time. The outlook, we are glad to see, is hopeful. The expenses inseparable from the opening years are being reduced; the cost of living and consequently of maintenance has fallen, and the revenue from patients' contributions has increased in proportion to the total expenditure, so that less of the cost is falling on the rates. Steady expansion rather than innovation has characterised the last two years, and modifications in policy are being postponed until the results of the Royal Commission become evident. The Maudsley draws its patients from many sources, and the medical superintendent states that every single mental hospital near London has referred cases during the last two years. Nevertheless, these patients form only a small proportion of the whole. Three times as many come from general or neurological hospitals; many "failures and misfits" come from social organisations, but the number of all these put together is doubled by those referred from their own doctors. This justifies the claim of the medical superintendent that he has never heard it suggested that the hospital encroaches on the province of private practitioners. A topographical survey shows that distance is a powerful factor, and that the majority of out-patients come from the immediate vicinity. This department is now the largest organisation of its kind in the country, and increased by 50 per cent. between the second and third years. The number in 1926 (11 months) was 1208. While the most obvious function of an out-patient department is to act as a sorting-house for the wards, the Maudsley is able, by virtue of its large staff of experienced clinical assistants, to give treatment to an increasing though limited number of out-patients. The medical superintendent, however, is careful to point out the danger of exaggerating the possibilities of out-patient treatment, for which only a few types of patients are suitable. During the period under review 1100 patients were admitted to the wards. New admissions are nearly always put to bed in the open air, but when their need for rest is satisfied every effort is made to provide them with some interesting occupation. All patients do a certain amount of work in the wards, and the carpenter's shop turns out beds, tables, lockers, washstands, and other articles of equipment. Even patients confined in the wards are distracted from their worries by instruction in handicrafts, of which there is a very wide range. That the results are both useful and attractive is shown by the ready market which the products obtain, so that the occupational department costs nothing but the salary of its officer. Wide use is made of physio- and electro-therapy, and two full-time masseuses are employed. There is a Swedish drill class in the garden daily, and all varieties of special and re-educational exercises are taught. The almoner's department performs some of the most arduous work of the hospital, for it visits patients' homes, undertakes services for them outside, places them in lodging and situations, and generally tries to ease the stress of their environment as much as possible. Some report of the pathological work appeared in THE LANCET for Oct. 29th (p. 924), and recent work continues the attempt to accumulate evidence of general bodily disturbance in the psychoses. Those who are interested in mental hospital work should not fail to study the full report.

THE REMOVAL OF HOUSE REFUSE.

IT is certain that the arrangements made by the majority of local health authorities for the removal of house refuse are very unsatisfactory from the standpoint of sanitation. The emptying of the dustbins and the passage of insufficiently covered dust-carts down the streets are both responsible for many complaints, especially on windy days; and the sorting of certain of the contents of dustbins, which is permitted in some areas, adds to the nuisance complained of. In this connexion many local health authorities do not practise what they preach. They seek to impress upon the general public the sanitary need for keeping the dustbin contents covered, while they are themselves great offenders and are constantly presenting bad object lessons. Indeed, it would appear that in this country we attach less importance to hygienic scavenging than do our continental neighbours, for in not a few centres of population upon the continent very complete and costly provisions are made for entirely preventing such nuisances. This is achieved by providing dustbins of special size and shape and fitted with special covers. The filled dustbin, tightly covered, is taken away, and a clean empty one substituted. This hygienically satisfactory arrangement is much more costly to install and to operate than the less sanitary methods prevalent in this country. There would be a great difficulty in getting owners and occupiers to provide the more expensive special dustbins, and it is not likely that the local authority would be prepared to provide them; but any suggestion which takes this difficulty into account and which promises to abate a frequent source of nuisance ought to be thoroughly tested. Some instruction may be gained from a visit to the Public Works, Roads, and Transport Exhibition which remains open at the Royal Agriculture Hall, Islington, until 7 P.M. to-day (Saturday). Here may be seen a dust-cart of the most recent type [1] with low loading level and mechanical tipping gear, for which it is claimed that it makes the operation of collection and removal practically dustless from door to destructor. In this cart the roof has a series of openings on each side which are covered with light metallic shutters, each connected to a foot-bar a few inches above the pavement level. When the loader puts his foot upon these bars as he lifts the bin the shutters open, to close again so soon as the bin is emptied. It remains, of course, to be seen whether the act of filling is dustless in practice, but sanitary authorities will have no excuse for continuing the old insanitary methods when once the problem of a dustless removal is solved in a satisfactory way. No method, however, is likely to be regarded as satisfactory which calls for a more costly and special type of dustbin, or if its total costs would add much to the already heavy charge upon the rates of this particular public service.

GRASS DISEASE IN HORSES AND BOTULISM.

AT a recent veterinary meeting Prof. J. Russell Greig, of Edinburgh, attempted to explain the clinical symptoms of acute grass disease in horses as an excessive stimulation of the sympathetic nervous system, due probably to overactivation of endocrine glands. No bacterial toxin, he said, is known to be a specific sympathetic stimulant. Veterinary opinion is certainly crystallising towards the view that so-called grass disease in horses is not equine botulism. It is probable that some of the outbreaks of so-called forage-poisoning in horses and cattle are due to the formation of a botulinus toxin in spoiled ensilage. Further, it is known that the South African disease of cattle termed lamziekte is due to the ingestion of a botulinus toxin formed in the bones of cattle which have died on the veld, the tendency for the cattle to eat the bones being due to pica caused by phosphorus deficiency in the soil. A similar condition to lamziekte has been found in Tasmania and attributed to botulinus toxin. Quite recently it has been shown that a botulinus toxin formed in the dead bodies of rats in stables in South Africa is very probably the cause of illness and death in horses, and there is reason to believe that it may yet be shown that such circumstances may cause illness and death in cattle and horses in other countries. Grass disease symptoms in horses, however, bear little or no resemblance to botulism in horses as can be demonstrated by feeding or subcutaneous inoculation of horses with botulinus toxin. Such experiments have shown that the horse is comparatively insusceptible to botulinus toxin whether fed or inoculated. Horses which have been infected experimentally by botulinus toxin show paralysis with inability to rise, the tongue hanging out, and salivation, while the mental faculties as well as those of sight and hearing are retained to their normal extent and little or nothing can be found in the way of post-mortem lesions. This is analogous to human botulism, but quite unlike equine grass disease. Moreover, grass disease occurs under conditions in which it is impossible to demonstrate that the victims have had any fodder other than the grass they pick up when at pasture, a feature which in itself almost excludes botulism, which presupposes some place where the bacillus can grow and multiply and produce its toxins outside the body. Grass disease is strictly confined to certain localities, where the *Bacillus botulinus* is ubiquitous. If it were feasible for herbivorous animals to develop botulism by the ingestion of the bacillus at pasture with the subsequent development of the toxin in the alimentary canal there would be no herbivorous population left. It is possible to demonstrate the presence of *botulinus* in the alimentary contents of herbivora, but clearly they do not produce their toxins there. Filtration of alimentary contents with concentration of the filtrate and inoculation into animals has failed to demonstrate toxin in grass disease. To prove that botulism is the cause of an outbreak in animals one must demonstrate the toxin in the suspected feed or in the gastric contents of the animals which have exhibited symptoms, and these symptoms must bear a resemblance to experimental botulism in the species. On the above grounds it would appear that veterinary opinion is justified in concluding that grass disease is not botulism.

SPEECH TRAINING AND STAMMERING.

A DISCUSSION on Nov. 8th, the first day of the International Conference on Speech Training held in the lecture hall of the Royal Society of Arts, afforded an excellent example of coöperation between those, medical and non-medical, whose work brings them into contact with the difficulties involved in speech production and particularly the treatment of the stammerer. Miss Elsie Fogerty, who on behalf of the Central School of Speech Training and Dramatic Art had organised the Conference, believes that speech and voice trainers should submit their practice to persons competent to judge the soundness of their physiological and psychological methods, and the selection of speakers accordingly included names well known in the specialties of laryngology and clinical psychology. Representatives of the clinics of the London County Council and of at least four special clinics attached to general hospitals took part in the discussion, and the speakers are to be congratulated on offering a wide range of opinion which nevertheless included no incompatibilities and could be brought together under one general principle. The interest of speech defect, especially stammer, has to some extent passed from the *how* of its production to the *why* and, since the *why* is a problem of behaviour and problems of behaviour contain infinite factors, it was not surprising to hear one speaker dwell upon the stammerer's poor sense of rhythm and turn to hexameter verse and the fox-trot for hints as to treatment, whilst another, in discussing the relation-

[1] Freighter dust-cart: special dustless loader type. Shelvoke and Drewry, Ltd., Letchworth, Herts.

ship of stammer and left-handedness, appealed to the Old Testament story of Ehud for proof that the people of those days recognised the rebellious and self-contained temperament of the left-hander. The speeches as a whole indicated a great advance in the understanding and treatment of a most distressing condition, and it is a pleasure to draw attention to the painstaking and unobtrusive work now being done on a disability that offers little opportunity for spectacular triumphs and yet affects the efficiency and happiness of many people.

THE TRIAL OF ADELAIDE BARTLETT.[1]

AT 4 A.M. on New Year's Day, 1886, Dr. Alfred Leach, of Charlwood-street, Pimlico, was called out to the lodgings of Mr. and Mrs. Edwin Bartlett in Claverton-street close by. He found the husband dead. The cause of death was a mystery till the post-mortem examination showed sufficient chloroform in the stomach to explain it. A few days earlier Mrs. Bartlett had obtained a supply of the drug through the Rev. George Dyson, a Wesleyan minister who was a close friend of the family and whose regard for Mrs. Bartlett had been by no means discouraged by her husband. Her reason for wanting the chloroform was, she said, that Mr. Bartlett suffered an internal complaint which caused violent paroxysms; it was essential to quiet and soothe him. Mr. Dyson bought 1 oz. of chloroform rather surreptitiously, but otherwise acted in a straightforward manner, and, when he found out that Mr. Bartlett's death was due to this drug and that the internal disease was a myth, he was honestly perturbed. Mrs. Bartlett gave to Dr. Leach a remarkable and entirely different explanation of her purchase of the chloroform. Suspicion naturally hastened upon her and a coroner's jury found her guilty of wilful murder, with Dyson as an accessory before the fact. At the trial at the Old Bailey the prosecution offered no evidence against Dyson, who thus became available as a witness for the Crown.

The Attorney-General, in his opening speech, addressed himself to the question how the chloroform got into the dead man's body. It might have been suicide, but there was no ground for supposing any such intention. It might have been swallowed by accident, but chloroform was a drug no man could take inadvertently. The only remaining possibility was that it had been administered by some third person. The theory, therefore, was put forward that there was first an external application inducing stupor and then the conveyance of the drug into the stomach while the man lay wholly or partly unconscious. The defence maintained the impossibility of such an operation, and all the medical witnesses were examined and cross-examined at length upon their experience and opinion of so unusual an occurrence. The problem of motive was complicated by the strange story of her marital relations which Mrs. Bartlett had told to Dr. Leach, but the issue of the trial really depended solely upon the scientific evidence. The jury's verdict stated that the case was one of strong suspicion; nevertheless, they found her "Not Guilty." Dr. Leach, writing in THE LANCET in April and May of 1886, hazarded the suggestion that Edwin Bartlett drank the chloroform out of sheer mischief to alarm his wife. It is as good a guess as another. The jury was doubtless right to acquit Adelaide Bartlett; still, as Sir John Hall observes at the close of his admirable introduction, some of those who think so may yet agree with Sir James Paget's remark that, once it was all over, she should have told us, in the interests of science, why she did it.

Some of the counsel in the Bartlett case happily still survive—Sir Edward Clarke and Sir Harry Poland (though neither had then been knighted), and Mr. Mead, the police-court magistrate. Russell, the Attorney-General, was not at his best; perhaps he was distracted by the campaign over Gladstone's first Home Rule Bill, then beginning. Clarke, his opponent, had, with characteristic industry, applied himself assiduously to the scientific side of the case. As in the Penge murder charge nine years before, he realised that acquittal would depend upon his handling of the medical witnesses. His autobiography relates that for a fortnight before the Bartlett trial he put aside all other work, forensic or Parliamentary, and devoted himself to studying in the British Museum and in his own library all that had been written about chloroform. His final address to the jury is a masterpiece of eloquence and advocacy, and his client had good reason to write him the letter of gratitude which Sir John Hall prints in facsimile.

[1] Notable British Trials Series. Edited by Sir John Hall, Bart. London and Edinburgh: William Hodge and Co. Pp. 402. 10s. 6d.

CHRONIC INFECTIONS AS A CAUSE OF ASTHMA.

IT is well known that asthma is often associated with chronic infection of the bronchi or nasal sinuses. In a recent paper[1] Dr. John Eiman puts forward the theory that in these cases the disease is due to sensitisation of the body to bacterial and other proteins present in the infected secretions and reabsorbed through the inflamed mucous membranes. In a series of asthmatic cases he diluted the secretion from the bronchi or sinuses and passed it through a Berkefeld filter. The filtrates which were found to be sterile were called "secretion filtrates"; they mainly contained products of the splitting of the secreted proteins, with some autolysed bacteria and their soluble toxins. A small amount of secretion was also diluted with saline and 1 per cent. glucose, incubated for 48 hours, and passed through a Berkefeld filter. This was called "soluble toxin" and was chiefly composed of soluble bacterial toxins, together with products of the splitting of secreted proteins and some autolysed bacteria. Dr. Eiman further prepared vaccines from the chief organisms of the sinuses and bronchi. The patients were then given intradermal injections of 0·1 c.cm. of "secretion filtrate," "soluble toxin," and vaccine, and the following three types of reaction were observed: (1) Positive reactions to secretion filtrates and soluble toxins but not to vaccines; (2) positive reactions to soluble toxins and vaccines but not to secretion filtrates; (3) positive reactions to all three. Normal individuals received injections in each case to serve as controls, and only when the patient reacted positively and the control was negative were the reactions considered to be allergic. By the use of controls it was found that the positive reactions with "secretion filtrates" were reduced from 95 to 77 per cent., with vaccines from 96 to 13 per cent., and with "soluble toxins" from 100 to 4 per cent. Whenever an "allergic" reaction was given with any of the three preparations it was used in treatment, the severity of the intradermal reaction being a guide to dosage. "Secretion filtrates" were given every fourth day, with vaccines and "soluble toxins" alternating in the intervals so that the patient received an injection every other day. The dosage was gradually increased. By this means 54 patients out of 86 were said to be relieved, besides 18 who were improved. Dr. Eiman considers that half the people whose asthma cannot be traced to a supersensitiveness to animal and plant proteins, pollens, or foodstuffs, have been sensitised to the proteins of their own secretion. He points out that administration of the filtrates should be regarded as a merely symptomatic treatment of asthma and that the main object should be the elimination of infections. For this reason he uses the autogenous vaccines and "soluble toxins"; whilst in another paper in the same journal Dr. Edward McGinnis draws attention to the part which the surgeon can usefully play in the removal of septic foci before they have had time to sensitise the patient. In all investigations of this kind, however, it has to be remembered that almost any new treatment will

relieve asthma in a large proportion of cases if it is sufficiently impressive to capture the victim's imagination.

HOSPITALS IN CHINA.

Dr. James L. Maxwell, executive secretary of the China Medical Association, has written three articles for the *China Medical Journal*, in which he deals with the position in which the hospitals in Southern, Central, and Northern China, and the medical schools throughout the country, have been placed owing to the present period of political disturbance and civil war. As regards the medical schools, he writes that out of a total of nine, five, or possibly six, may be able to carry on without serious hindrance; one will continue on a limited scale, and two will remain closed. The position produced by the interference with medical education is a very serious one, for there is a decrease of nearly 50 per cent. in the output of fully qualified doctors from the best medical schools in China, and it will be several years before the former figures, which were themselves far below the needs even of the mission hospitals in China for Chinese doctors, can again be reached. Many of the Government and other medical schools, too, are closed, and the majority are in a desperate financial condition. A crisis has thus arisen, for the mission hospitals, nearly 300 in number, are largely dependent on these schools for a supply of qualified men; already the foreign hospital doctors are carrying all the burden they can, and more than they should, and the prospect of an adequate medical profession for the country becomes more and more distant.

As regards the position of the hospitals under the Southern and under the Northern Governments, Dr. Maxwell summarises the whole position, and though there is no intention on his part to judge the political situation, the figures, he says, speak for themselves. Under the Southern Government, out of a total of 165 hospitals 21·2 per cent. are running more or less normally, as compared with 70 per cent. under the Northern Government, which is responsible for 70 hospitals; 34 per cent. are running under temporary arrangement in the south, and 24·3 per cent. in the north. Of the number of hospitals that have had to be closed, there are 33·3 per cent. under the Southern Government, and only 5·7 per cent. under the Northern Government. The province of Yunnan has been excluded from these figures, as no accurate information of the position could be obtained, and also Honan, for the position of which no one party can be held responsible.

AMERICAN UNIVERSITIES.

THE amazing progress of the medical schools in the United States, the princely benefactions of America to medical education in this and other countries, and the constant stream of students and teachers who pass to and fro across the Atlantic all combine to make American education a matter of real and in many cases of personal interest to an increasing number of medical men in this country. Medical education can never stand properly by itself, and though it does not say very much about the preparation of the doctor we can heartily commend to the careful consideration of all members of the faculty of medicine a pamphlet [1] in which the Academic Registrar of the University of London urbanely records his impressions of a visit to the universities in the United States which he paid last year under the auspices of the Laura Spelman Rockefeller Memorial. In a comparatively short time energy and enthusiasm have applied exceptional wealth to the building up of what Dr. Deller describes as the most impressive monument to a faith in university education which the world has yet seen. And the faith is widespread, for it leads, for good, to the exemption of all universities from local and federal taxation and, for bad, to the supposition th a university education must be open to everyone a hence to an unmanageable host of students. But o of this flooding with ill-prepared school-boys, many them quite unfit for teaching of a university standa is emerging a development of great interest—t post-graduate university—in which is visible a part return to the old idea that the prime business of university is to be a body of learned students occupi in the pursuit of knowledge rather than an organisati for teaching undergraduates, as modern here imagines. In this country universities, especia Oxford and Cambridge, are governed by about as pu democracies as ever have been; the autocratic rule the American President is viewed, on the whc favourably by Dr. Deller, but it is evident from wh he says that the intellectual freedom of the teacher still far from secure. Many students, he writes, a seriously handicapped in their thought and in th expression of thought and are unprepared for serio study of any kind by a lack of vigorous discipline the use and value of words—a remark which will sympathetically received by those who read t examination papers of English medical students. mention only a few points; those who care for high education should read the whole—without envy a without malice.

NOISE AND OUTPUT.

THE influence of sound on mental and physi activity has been more talked about than studi yet the sounds of modern life, by road or rail, factory or in mill, are ever increasing in complex and in kind. Although music has been used increase output, in industries as well as in arm it is generally held that the effect of irregular n is to reduce efficiency. Thus Münsterberg[1] qu the case of a woman in a printing shop whose w improved by 25 per cent. when she was remov from being near a passage where trucking was d and Florence[2] instances a factory where the rate absence for men was highest (6·8 per cent.) in noisiest department, as compared with 6·5 for dep ments where air conditions were poorest, 6·4 wh muscular strain was heaviest, and 6·3 where e strain was greatest, the rate in all these departme being in excess of an average for the whole fact which was 6·1. More intensive investigations now reported[3] from the Colgate University in United States, where typists were set to work i test-chamber containing a noise-machine wh reproduced the environment of an ordinary busi office. It made sounds like an electric motor, lik motor siren and a telephone bell, intermittently automatically, and rotated ball bearings in an drum; in the test-chamber the effect was increa through reverberation. Working metabolism measured every 15 minutes by collecting and analys expired air, and the speed of work and errors throu out two-hour periods of work were carefully no Under quiet conditions the average time per le typed had improved by seven seconds at the en the two-hour period, but when the noise-mac had been in full blast the time at the end was seconds longer than at the beginning. In o words, the artificial noise was found to inhibit warming-up effect. Under these conditions it noted that the faster the worker the greater was harm done by the noise. Under quiet conditi working metabolism was 52 per cent. higher t resting metabolism, but when the noise was tur on it became 71 per cent. higher, although the out of work was less. The 19 per cent. increase see to be expended in a general tenseness of the en musculature. Somewhat unexpectedly it was fo that the energy expended under noisy condit did not increase as the work proceeded, and t

[3] The Measurement of the Effects of Noise on Wor Efficiency, D. A. Laird, Journal of Industrial Hygiene, Oct 1927.

he difference between the amount of energy xpended in the two environments was the same fter two hours as it was at the beginning. The uggestion is made that noise should be considered s a possible contributory cause of neurasthenia and atigue, and the experiments support conclusions hich many people will have drawn from their own ensations while at work in noisy places. The xperiment may not, however, give an accurate idea f the amount of damage done by ordinary noise. t is doubtful whether a machine can accurately eproduce the conditions of a factory or office, or its performance must always be attracting the onscious attention of the workers, whereas the hum f traffic and the familiar sounds of industry are ardly noticed by those who live among them.

HE HOSPITAL PROBLEM OUTSIDE LONDON.

THERE are few departments of the national activity which statistics are of greater practical value than ie vast field covered by the voluntary hospitals, id there is no more illuminating compendium of cts and figures relevant to those institutions out-de London than the annual report issued under e auspices of the Order of St. John of Jerusalem id the British Red Cross Society. The report for 26, the work of Mr. R. H. P. Orde, the Director of ospital Services of the Joint Council of these stitutions, which has been issued this week, is a ank and suggestive document, which not only istles with figures, but discusses some of the most fficult of the outstanding problems affecting the ture of the voluntary hospitals. Perhaps the ost important of these problems is the nature of e relationship which seems likely to be established tween the voluntary hospital and that provided public authorities, and the Joint Council recently ked the administrative officers of certain large ovincial voluntary hospitals to state their personal ews on the subject. Their answers form an appendix the report. They are very varied in character d form a curiously interesting conspectus of the inions of a number of experts looking upon the me subject by the light of long and varied experi-ce. The main point upon which there is general reement is that the voluntary system must be served at all hazards, though one or two of the mmentators are inclined to think, or fear, that ything in the nature of fusion or coördination tween the voluntary hospitals and the poor-law municipal institutions would result in serious advantage to the former, or even to their ultimate inction. Mr. Frank G. Hazell, general superin-tident and secretary of Manchester Royal Infirmary, es so far as to declare that "relationship between two is constitutionally impossible."

Much stress is laid upon the traditional and in-ained "dread" of the poor-law institution because its "pauper taint," but any system of coördination h as has been dimly envisaged by Mr. Neville amberlain would necessarily be founded upon the moval of that taint. Many suggestions are made meeting the pecuniary difficulties which too often round the work of voluntary hospitals—grants in from the State; loans for capital purposes, free interest, repayable over a series of years; grants m the Road Fund on account of motor accidents; general adoption of an efficient contributory tem; contracts between the public authorities the hospitals to do certain kinds of work for an eed sum. The last-mentioned system is already operation in Oxfordshire and Berkshire, with the ult, as the Rev. A. G. E. Sanctuary, of the Rad-fe Infirmary at Oxford, reminds us, that the dcliffe has been able to maintain a maternity partment which has greatly reduced the infant rtality-rate in the city of Oxford. The cost to the ford council is £1000 a year, a bagatelle compared the amount it would have to expend to maintain own system upon lines of equal efficiency. There however, a considerable agreement that, given a reasonable working system of coöperation, there is room for both forms of institution, and that the adoption of such a system would avoid the need for much further extension of the voluntary hospitals, which would thus be enabled to concentrate upon improvements and increased efficiency.

Coördination almost necessarily involves some differentiation of function between the two types of hospital, and the administrators who have contributed to this valuable symposium are, in the main, of the same opinion as the medical profession, that the municipal institutions should, among other things, take chronic, infectious, and incurable cases, the voluntary ones being reserved for cases of obscurity or difficulty requiring a high degree of technical skill, special diagnostic facilities, and so on. They would also treat all accidents and emergencies, and would devote themselves with greater diligence than ever to teaching and research. Another matter upon which stress is laid by more than one writer is the desirability of some scheme of central control for the avoidance of overlapping and the clear definition of function, which might not be identical in every instance. The paying patient, for example, might sometimes be more conveniently dealt with in the municipal than in the voluntary hospital, and some authoritative means might be needed for deciding the choice. Amid these diverse views one fact stands out—the medical staffs as a whole are strongly in favour of the preservation of the voluntary system with the working of which they are so intimately associated. That is not to say that they are oblivious of the powerful help to the health of the nation which could be afforded by the rate-aided institutions were they linked up with those which depend for their usefulness upon public benevolence and systematised public recognition of the services which they render. The problem of how best to forge the link is assuredly not insoluble.

THE DENTAL BOARD.

Sir Francis Acland gave a brief account of the Dental Board's educational work at the opening of the thirteenth session of the Board on Nov. 8th. Of over 50 students financially assisted throughout their curriculum, all but six or seven, he said, were now in public or private practice; furthermore, 150 out of 170 ex-Service men assisted by Government grants were also established practitioners. The standard of applicants for bursaries is satisfactory enough, although, as the Board's Registrar points out in his letter on p. 1100, the number of applicants is still insufficient to supply the probable need for dental practitioners, and steps are being taken to make the offer of financial assistance more widely known. The remaining part of Sir F. D. Acland's address was largely taken up with considering the education of the public in dental hygiene. The Board's travelling dental exhibits had, he said, been in great demand, railways and tram services were displaying educational posters, and an intensive campaign conducted in a northern county had resulted in surprising sale of tooth-brushes and creams. On the vexed question of dental clinics the Chairman of the Dental Board made no pronouncement, preferring no doubt to await the report of the special committee appointed by the Minister of Health. Finally, he expressed some surprise at the number of cases in which disciplinary action of a sort was being required. The few delinquencies coming before the Board this session were chiefly matters of advertisement, canvassing, or insobriety, but the Registrar spends no little time in bringing home to individuals the pains and penalties of practising dentistry without being on the Dentists Register.

Sir Arthur Keith, F.R.S., will take the chair at the third annual Norman Lockyer lecture, to be given by Dean Inge in the Goldsmiths' Hall on Monday, Nov. 21st, at 4 P.M. The subject will be Scientific Ethics.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCL.—THE TREATMENT OF POST-PARTUM HÆMORRHAGE.

II.* FROM LACERATION.

THE characteristic feature of this type of post-partum bleeding is that it occurs with a firmly retracted uterus, which is easily felt and grasped in the abdomen. The bleeding is not rapid and severe, but appears rather as a steady trickle that, if not checked, may in time give rise to serious symptoms. Should it be accompanied by immediate and marked collapse, it would suggest rupture of the uterus or an extensive laceration of the cervix extending into the base of the broad ligament. Inversion of the uterus, also associated with symptoms of shock, is excluded by the presence of the firmly contracted uterus in the abdomen. Sometimes blood collects in the distended vagina, especially in the posterior fornix, and escapes slowly, so that the state of affairs may not be immediately obvious. For this reason it is a sound practice when there is a steady trickle of blood to press down the retracted and empty fundus uteri at intervals so as to express any blood or clot that may have collected in the vagina. Should each expression result in the expulsion of blood and a mass of clot, it will be almost certain that the hæmorrhage is from a laceration of the cervix or other part of the genital tract. Bleeding from the vulva or vestibule is readily detected by inspection.

Causation and Preventive Treatment.

Trauma of the soft parts is most likely to occur in difficult and instrumental labours, especially those due to malpresentation and misfits. Rapid delivery through incompletely dilated soft passages always carries with it the risk of extensive laceration. One of the reasons why so much emphasis is laid on not attempting delivery by the forceps till the cervix is fully drawn up over the head, and on slow delivery in placenta prævia once compression of the placental site had been secured, is the serious hæmorrhage that may result from lacerations produced thereby. The soft parts about the vestibule and round the pubic arch may be cut cleanly by pressure of the blades of the forceps or other instruments against the hard bone. The tearing of soft parts, such as the perineum, by overstretching is rarely associated with bleeding of any moment, as the vessels are torn rather than cut. Occasionally similar accidents may arise in a natural labour, particularly if associated with strong pains and rapid expulsion. Early rupture of the membranes followed by rapid completion of the labour by the natural powers may result in cervical and vaginal tears, but here again serious bleeding is very unusual because the tissues are not clean cut.

The *preventive treatment* is obviously to avoid as far as is possible by careful antenatal supervision the complications of labour likely to give rise to laceration, and to refrain from rapid delivery through the insufficiently dilated soft passages.

Treatment.

Treatment, when the condition has arisen, must depend on the severity of the hæmorrhage, the site of the laceration, the circumstances in which the labour is conducted, and the facilities available. Bleeding from clean-cut lacerations of the vestibule, or vagina near the outlet, which can be easily seen and reached, may be controlled by underrunning with a catgut stitch, either mattress or double cross-stitch. Similar treatment would clearly be best in all cases of bleeding of more than a minor degree were it not that a thorough investigation of the higher reaches of the genital tract is difficult and requires good exposure, good light, skilled assistance, and often difficult manipulations in circumstance that are a great handicap to success. Hence it i essential that full consideration be given to what i possible and effective as well as to what might b done under hospital conditions.

When the bleeding is not severe, and is represente by a pooling of blood in the vagina, which trickl out at the vulva in a slow stream and is expelled a clot and fluid blood by occasional expression, vaginal douche as hot as the woman can bear, or she is anæsthetised, at a temperature of 115–118° F should be given at once. That will usually suffic unless a large vessel is divided, but before leavin the patient, time should be given to make sure tha blood is not collecting again in the vagina.

In the more serious cases, and when the douche ineffective, the next procedure to be adopted mu be determined by what is possible in the circumstance The best would be to give an anæsthetic and, wit the patient in the lithotomy position and a weighte speculum of the Auvard type in the vagina, examine the cervix and vaginal fornices thoroughl discover the source of the bleeding, and suture tl laceration with catgut. Even under the favourab conditions of a hospital, with an electric headligh and skilled assistants to retract and sponge awa the blood that obscures the bleeding area, this ma not always be a simple matter, though generally tl cervix can be brought down by volsellum force and sutured. The difficulty is greater with laceratio running out into the vaginal vault or up into tl lower uterine segment. To advise measures this kind for ordinary family practice would be counsel of perfection that could rarely be followe The hæmorrhage, however, can always be controll by firm packing and pressure downwards on t retracted uterus. Either with the woman on h left side, or, if there is adequate assistance, in t lithotomy position, the vaginal vault is stuffed tight with sterile gauze or an improvised and boiled dre ing, and with a hand on the abdomen the uterus pressed firmly down on the plugging, whilst t gloved fist of the other hand presses the dressing against the cervix and vaginal vault for a time t more material is ready to be inserted; once it is place, the compression between the hands is resume and this packing goes on till there is a tight vagin plug against which abdominal pressure can be mad a tight binder over a graduated compress bel applied to maintain it. If the bleeding is seric and time is needed for the preparation of the dre ings, it may be controlled for the time being by form of bimanual compression, in which the glov fist, covered so far as possible with a sterile s dressing, is pressed up against the vaginal vault a lower part of the uterus, whilst the external ha presses the body down on it, till time is gained fo more permanent method of compression by pluggi In other words, if the bleeding area is high up, t best plan is to exercise pressure manually over wide area of the vault till it is possible to dev some other means of continuing the compressi If the laceration extends into the lower uteri segment, and even if it is complicated by prola of bowel, firm plugging, after return of the prolaps intestine, is the best emergency measure.

Sometimes it may be possible to carry out an int mediate plan, by getting hold of the torn cervix vaginal vault with volsellum forceps (or other form forceps or clamp) and checking the bleeding by pressure of the forceps or by applying traction upon and leaving it there till arrangements can be made a more effective control by suture. When the po bilities of infection are considerable, plugging is sa than suture, for it leaves a free exit for discharg Infected wounds are best left to granulate, and fe first thing to be done, should infection occur af stitching a tear, is to remove all sutures to allow escape of discharge.

Indeed, in all severe lacerations that call suture, once the hæmorrhage is under control it's best to postpone any further interference till adequ

* Part I., Placental Post-partum Hæmorrhage, appeared last week.

sistance and suitable conditions can be arranged. such an accident as a perineal laceration involving e rectum, it is better to adopt temporary measures here conditions are unfavourable, and postpone the turing for 12 hours or so, rather than try to make e best of a bad job in the middle of the night with poor light and no skilled assistance. In circumances such as these, and in procedures where curate suturing is essential, the risk of failure is sened by waiting till satisfactory arrangements n be made, and increased by attempting a difficult sk under unsuitable conditions.

The treatment of post-partum hæmorrhage from eration may be summarised by saying that when does not yield to a hot douche, compression by a ig is better than the theoretically more efficient ture in all save wounds which are low down and sily seen. Suture of tears through the cervix into e base of the broad ligament may fail to hieve its object, because when the cervix is drawn wn, the uterus comes down with it, but not the rametrium, and the vaginal walls may be sutured d bleeding continue into the space above. On the ier hand, the attempt to close the space by encling it with a curved needle runs the risk of luding the ureter. Some 20 years ago Fritsch ted that, as the result of observations on cases which secondary operation or post-mortem examiion had been done, bleeding was checked by ure only in those cases in which it would have sed without it. As plugging is not always well ne and much blood may be lost during preparations and insertion, he urged that for immediate treatment the best plan was to grasp the labia majora in the left hand and press the relaxed pelvic floor upwards into the pelvis, whilst the right hand pressed the uterus deeply into the pelvis so as to compress the bleeding surface between the two hands. This pressure can be maintained for half to three-quarters of an hour, and has the advantages of immediate applicability, compressing the bleeding surfaces so as to leave no dead spaces in which blood may accumulate, and being entirely extra-vaginal, so that the risks of infection are greatly lessened.

As both plugging and suture, particularly the latter, may be followed by the formation of a hæmatoma, the warning may be given to watch for swellings in the broad ligament that may come up over the pelvic brim and appear as a hard mass on that side of the middle line on which the laceration has occurred. Also if a douche is given it should be under low pressure, with the patient's hips low and the body propped up, and no poisonous chemical should be used. Heat is the agent in checking hæmorrhage. Absorption from extensive raw areas is rapid, and communication with the peritoneal cavity is a possibility to be borne in mind in serious lacerations. If there is prolapse of bowel, or other definite evidence of a rupture into the peritoneum, plugging only should be adopted.

Obstetric Physician, St. Thomas's Hospital.

MEDICINE AND THE LAW.

Infanticide Act: "Newly Born Child."

WHEN Parliament passed the Infanticide Act in 22 critics observed that the language of the statute s too indefinitely expressed. A woman might be nd guilty of infanticide instead of murder if, upon l for the murder of her newly born child, the jury e of opinion that she by some wilful act or omission used its death, but that, at the time of the act omission, she had not fully recovered from the ct of giving birth to the child, and that, by reason reof, the balance of her mind was then disturbed. s enactment, said the critics, was strangely vague. at is a "newly born child"? What is the mean- of "not fully recovered"? Some light has now n thrown upon the first of these two questions, the Court of Criminal Appeal has decided that Justice Talbot was quite right in holding recently the Central Criminal Court that a baby a month could not be deemed "newly born." It had n proved at the trial that the baby was born on gust 19th. The mother confessed that on Sept. 21st "put a napkin round the child's neck and twisted ecause I had nobody to mind him and no money." was contended on her behalf that the jury should e been allowed to say whether or not the child newly born within the meaning of the Act, ether or not the mother had fully recovered, and ether or not her balance of mind was disturbed by recent confinement. Counsel urged that mental urbance normally continued for six weeks after finement; puerperal insanity and melancholia ht appear at any time up to six or eight weeks r the birth. The Lord Chief Justice, however, l that it was not enough to argue that the mother had a child and had not fully recovered from her finement; the word "newly born" could not be ored. Unless the child were "newly born," the y could not find a verdict of infanticide. The rt was not proposing to define "newly born d," but it was satisfied that a child of more than alendar month in age was not newly born within meaning of the Act. It thus appears that Mr. tice Shearman was wrong when, in the case of x *v.* McConnell, tried at the Reading Assizes four rs ago, he allowed the question whether a child weeks' old was "newly born" to go to the jury for decision. When, following a suggestion by the late Dr. J. W. Ballantyne, of Edinburgh, the medical profession employs the term "neonatal mortality," it is referring to mortality in the first month of postnatal life. It might be helpful if the legal profession would adopt some similar standardisation of language.

The Infanticide Act was passed to end the grim farce of sentencing women to death for child murder when everyone in court knew that the Home Office would refuse to allow the capital sentence to be carried out. Judges disliked the situation acutely. Lord Loreburn proposed, about 20 years ago, to end the difficulty by giving a judge power to say that child murder was merely manslaughter. Subsequently Lord Alverstone brought in a Bill to allow judges to record the death sentence in such cases without pronouncing it in open court. Neither of these proposals became law.

Death of Mr. Harnett.

Mr. William Smart Harnett, remembered for his long litigation against members of the medical profession, was found drowned in the Union Dry Dock at Poplar on Nov. 10th. It has been stated in the daily press that, in consequence of that litigation and the inquiry which followed it, Parliament passed legislation in 1925. If this is so, it was a somewhat remote result. The Act of 1925 amended not the Lunacy Act but the Mental Deficiency Act of 1913. The statute of 1913 permitted a judicial authority—i.e., a county court judge, stipendiary magistrate, or specially appointed justice—to make an order placing a mental defective in an institution for detention or under guardianship. The Act further created machinery whereby a person already under guardianship could be transferred to the greater restriction of detention in an institution; but it omitted to provide for the converse operation of transferring a person from detention to guardianship. The 1925 Act remedied the omission. It was supported by the Central Association of Mental Welfare and by all who realised that, after a period of detention, persons are often so greatly improved in health that they can advantageously be transferred to guardianship—which, incidentally, is a more economical form of maintenance. But this rectification of a statutory omission hardly arose from the facts in Mr. Harnett's case; indeed, the changes in the law which that case indicated as desirable seem still to be far off.

Special Articles.

ON THE NUTRITIVE VALUE OF BREAD,

WITH SPECIAL REFERENCE TO ITS CONTENT IN VITAMIN B.

BY W. CRAMER, D.SC. EDIN., M.R.C.S. ENG.,
AND
J. C. MOTTRAM, M.B. LOND., D.P.H. CAMB.

IT has been said with truth that the food problem is the bread problem. The reason for this statement is that bread, like all cereal products, furnishes the most nutriment for its cost. Bread is consumed more regularly and in greater bulk than any other article of diet. The diet of the working man has been calculated to include on the average about 1¼ lb. of bread a day, representing about 60 per cent. of the total protein intake. Wheat, like most cereals, is rich in vitamin B, so that formerly the bread made from the stone-milled flour was presumably an important supply of vitamin B in the human dietary until the introduction of roller mills, about 40 years ago. The introduction of the roller mills and the almost exclusive use in this country of the fine white flour for the baking of bread has changed the situation completely. Observations are recorded in the literature (Osborne and Mendel, 1919) which show that the water-soluble vitamin B is not evenly distributed throughout the wheat grain and that the fine white flour now used almost exclusively in this country for human consumption is practically devoid of this vitamin. It would appear to follow that white bread is no longer an important supply of vitamin B in the human dietary in this country. Against this conclusion it has been argued that the deficiency of vitamin B in the white flour is made up by the yeast used in baking, since yeast is supposed to be exceptionally rich in this vitamin, and experiments have been recorded (Hartwell) which are supposed to confirm the contention that white bread contains a considerable and adequate amount of vitamin B. This contention was in such striking contrast to observations by previous observers (Hawke, Smith, and Bergheim) as well as one of us (W. C.) that in view of the outstanding importance of this subject a detailed investigation of this important problem seemed called for.

The recent work of Goldberger makes it necessary to define vitamin B. This author has shown that the water-soluble vitamin B contains two substances, one which can be recognised by its antineuritic action and by its rapid effect on growth, and another one which has a more delayed action on growth and which cures or prevents a condition in animals which he believes to be identical with pellagra in the human subject. This work has been confirmed recently by Chick and Roscoe. Goldberger speaks of the first-named substance as vitamin B proper. Since all the past work on vitamin B is based either upon the antineuritic effect or on the rapid effect on growth, this definition, which does not involve any alteration of recorded observations, appears to us to be the right one, and we have adopted it.

It is well known that wheats of different origin show differences in their chemical composition and in their physical characters. According to Bell and Mendel, they vary also in their vitamin content. They found that Marquis spring wheat contains two or three times more vitamin B than Minnesota winter wheat. Since such differences might introduce a fallacy it seemed essential to work with milling products of known origin and representing a fair average. We were fortunate in enlisting the interest of the directors of Hovis, Ltd., in this investigation, so that we were able to work with different milling products of known origin and also with bread baked with materials of known origin and in known quantities. We are especially indebted to Mr. A. E. Cressall, one of the directors of Hovis, for assisting us with his technical knowledge of the subject.

A brief account of the process of milling is necessar for the understanding of the problems involve The following account is based on data supplied t us by Mr. Cressall. The wheat grain consists endosperm which makes up the bulk of the grai about 77 per cent., the embryo, which constitut only 2 per cent. of the grain (and is richer in fat tha the endosperm), and the husk. The latter is made u of two layers, which are fused together—namely, t pericarp or modified ovary wall, and the testa or see coat. Immediately underneath the testa or seed co is a layer of differentiated cells, the aleurone cell In the process of milling the grain is disrupted and number of materials are obtained from it which a separated from each other by the size of the sie through which they are made to pass. In this mann the particles which go through the finest mes constitute white flour, of which about 70 per cen of the whole grain is obtained. The next coars material is called " sharps " or " middlings," and i the main this is made up of the inner skin of t grain together with the aleurone cells, with a slig admixture of endosperm and also of embryo. T coarsest material is the " bran," which is essential the outer skin, again with a slight admixture of t wheat embryo. The bulk of the embryo is separat from the other materials owing to its fatty natu This product, in which a considerable amount endosperm remains adherent to the embryo, is call technically the " germ." Thus as a result of milli one obtains the different materials in the followi proportions :—

	Per cent.		Per ce
White flour.. ..	70	Germ	1½–2
Sharps or middlings	14	Loss	½
Bran..	14		

All the milling products except white flour are so as offal and used for cattle food, except whe wholemeal or germ flour is being used for special kin of bread. The white flour may again be graded in t process of milling according to the requirements of t trade. The finest white flour is called " Patent This represents 60 to 75 per cent. of the total whi flour extracted in milling. " Straight run flour is simply the total ungraded white flour as obtain in the milling.

The first observations on the subject recorded in t literature (McCollum and Davies ; McCollum, Simon and Pitz) emphasised the richness of the wheat gra and especially of the wheat embryo in vitamin B, little as 2 per cent. of the wheat embryo in a di otherwise free from this vitamin being sufficient maintain growth over a long period in rats. T represents an actual weight of about 0·2 g. of whe embryo. Further investigations on the vitam content of the various milling products were made Chick and Hume, who used pigeons as test objec and compared the amounts of the various milli products necessary to protect against and to cu respectively avian polyneuritis which sets in when t birds are kept on a diet of polished rice. They fou wheat germ to be richest in vitamin B ; next ca bran, while white flour was so poor in vitamin B th by itself it was unable even to protect birds agai polyneuritis or man against beri-beri. Seve examples of beri-beri occurring in civilised communit living on a diet which was for some special reaso restricted, and in which white bread was the on cereal product consumed, are given in the Medi Research Council's Report on the Accessory Fo Factors. The vitamin content of wheat germ measured by its antineuritic potency is very hig Chick and Hume found that a dose of 2·5 g. a occasionally 1 g. wheat germ was sufficient to cure pigeon showing fully developed symptoms. It richer even than yeast, which is generally held to exceptionally rich in this vitamin. For pressed ye Chick and Hume found 3–6 g. to be the curative d in pigeons.

Bell and Mendel estimated the vitamin B conte of the various milling products—namely, " Pate flour "—i.e., white flour—" first and second clea

low grade and bran" and "standard middlings" and ompared them with the vitamin B content of the hole grain. Their observations, which were made on iice, were carried out so as to give the amounts of ie various milled products which had to be added to vitamin B free basal ration in order to supply the nount of the vitamin necessary for growth. This as 15 per cent. of the whole diet for spring wheat, id 40 per cent. for winter wheat. White flour was und to be so poor in this vitamin that it would have en necessary to give nothing but white flour—i.e., 0 per cent. of the diet in order to supply the animal ith an adequate amount of vitamin B. Such a diet ould be deficient in other respects and unable to aintain the health and growth of an animal. Com- ared with the whole unmilled grain, first and second ear were found to have the same content in vitamin B, low grade and bran" were twice as rich, and standard middlings" four times as rich as the whole ain. The standard middlings are stated to have ntained most of the embryo. The germ itself was und by Osborne and Mendel to be the richest part the grain in vitamin B, thus confirming Chick and ume's observations. The germ, in spite of its nallness, was found to contain as much as one-sixth the total amount of vitamin B present in the grain.

In the experiments referred to above, except those Bell and Mendel, no detailed description of the rious milling products is given, nor what percentages their products were obtained from the milling of the ole grain. In the experiments to be recorded andard wheat was used consisting of:—

	Per cent.		Per cent.
No. 1 N. Manitoba..	20	Plate	30
No. 2 ,, ..	20	Australian	10
No. 3 ,, ..	20		100

From this the following products obtained by illing were investigated: white flour, 70 per cent.; iddlings, 14 per cent.; bran, 14 per cent.; and rm, 1½–2 per cent.

The experimental details were as follows: Rats om 70 to 100 g. were used for these experiments. heir weight and temperature were taken once weekly, ways at the same time. They were kept on a basal tion completely free from vitamin B and consisting casein (especially purified), starch, olive oil, and the ual salt mixture, to which was added cod-liver oil. n such a diet the animals gradually pass into the rasmus characteristic of vitamin B deficiency, hich deepens progressively as manifested by cessation growth, followed by loss of weight and accompanied a progressive lowering of the body temperature. e lowering of the temperature is in our opinion a ore sensitive indicator of the absence of vitamin B an the weight, provided that the animals are kept i a room kept at a fairly even and warm temperature. does not seem to be sufficiently appreciated that e temperature of the animal room is an important tor in determining the rate at which a deficiency in amin B affects the organism. The animals were pt on the basal vitamin B free ration until the body nperature had fallen to about 36° C. Then the terial to be tested was added to the basal ration. the temperature returned to the normal in two eks, and the weight increased, the result is stated as omplete recovery." If the normal temperature was gained after a lapse of more than two weeks the ult is stated as "slow recovery." If the normal nperature was not regained the result is "no covery." In our experiments the changes in the ight curve corresponded almost always with those the temperature curve. In each experiment three s were fed together in the same cage on the same t. The germ used was sterilised germ, as used in preparation of Hovis flour. Experiments with sh germ showed that the method of sterilisation ployed in this process did not materially decrease e vitamin B content of the germ.

The results are shown in Table I., which gives the ounts per rat of the various milling products added 10 g. of the basal vitamin B free ration.

White flour contains so little vitamin B that the addition of as much as 7·5 g. to 10 g. of the basal ration per rat was unable to produce even a slow

TABLE I.

recovery. It may therefore for all practicable purposes be considered to be free from vitamin B.

The vitamin B content of yeast is of importance in connexion with the vitamin content of the various kinds of bread. In the Medical Research Council's report of vitamins it is stated that a rat on a vitamin B free ration requires the addition of 0·1–0·2 g. of dried yeast. This amount corresponds to 0·5–1·0 g. of fresh yeast as used for baking. For polyneuritis in pigeons the curative dose is given as 3·0–6·0 g. of pressed yeast, a dose more than twice as high as that of wheat germ (1–2·5 g.). Dunham gives 0·5 g. of dried yeast as the dose necessary to re-establish completely growth in young rats kept on a diet free from vitamin B. According to Kennedy and Palmer the vitamin B extent of yeast obtained from different sources as tested in rats varies considerably. They state "our results do not support the general belief that yeast is an unusually valuable source of vitamin B." One of the most satisfactory preparations tested by them was a baker's yeast, of which 0·6 g. of the dried material was required to establish satisfactory growth. A comparison with wheat embryo showed that the latter was a most reliable source of vitamin B. Drummond, McCollum, Hawk, and collaborators have given similar figures of 0·6 g. of dried yeast. Our own observations on rats were made with dried baker's yeast, dried at 100° C. An amount of 0·5 g. of dried yeast equal to 1·5 g. of fresh yeast was found necessary to ensure complete recovery from vitamin B deficiency. Taking all these observations together, we shall therefore not understate the vitamin B content of fresh yeast as used for baking if we put it equal to that of sterilised wheat germ, of which, as stated above, 0·5 to 1 g. are required. It may be pointed out that these absolute values are actually more in favour of yeast than the relative

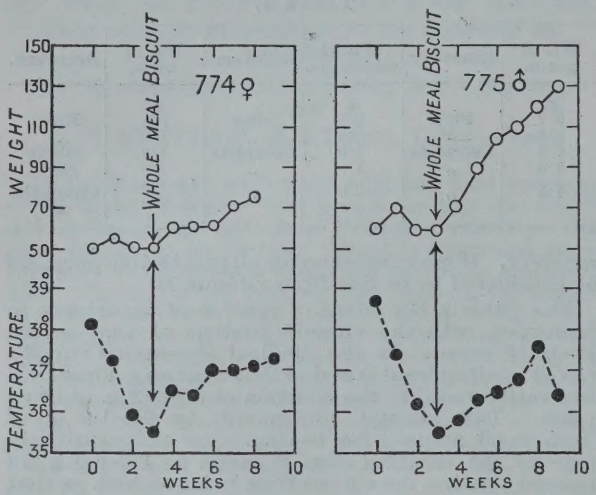
values given by the report of the Medical Research Council, p. 41, where the vitamin B content of yeast is given as representing only 60 per cent. that of wheat germ.

These data enable us to compare the vitamin content of the various kinds of bread: ordinary white bread, wholemeal bread, and germ bread made of Hovis flour, which contains one part of sterilised germ and three parts of patent flour. Vitamin B is so resistant to moderate heat that, as pointed out in the report of the Medical Research Council, the loss resulting from

the process of baking is only slight. If we put the vitamin content of 1 g. of wheat germ as 100, then middlings are 50, bran 33, white flour 0, yeast 100. The amount of yeast added to flour in the baking of



bread is 2½–5 lb. per 280 lb. of flour—i.e., a maximum of 2 per cent. as given in Table II.

These figures offer a striking comment on the statement which has been made repeatedly that the absence of vitamin B from white flour is of no practical importance, since in the process of baking yeast is used which is supposed to be so rich in the vitamin that it makes up for its absence in the flour. This statement is obviously made without any quantitative consideration either of the small amount of yeast used in baking or of its vitamin content as compared with that of the various milling products of the wheat. The significance of the figures given in Table II. is even more striking when we try to estimate the amount of the various kinds of bread necessary to furnish an adequate supply of vitamin B under conditions in which bread is the only source of supply of this vitamin. From the data given above it follows that the minimum amount of vitamin B necessary to enable a rat rapidly to resume growth and to regain a normal temperature on the basal ration is contained in 0·5 to 1 g. of wheat germ and in about 1 g. of fresh yeast. It may be added that this is by no means the optimum amount which may be a good deal higher. We may put the minimum amount, therefore, at 50 to 100 units. If bread is the only source of supply of this vitamin, then a rat in order to get this amount would have to consume daily (calculated as for dried bread) :—

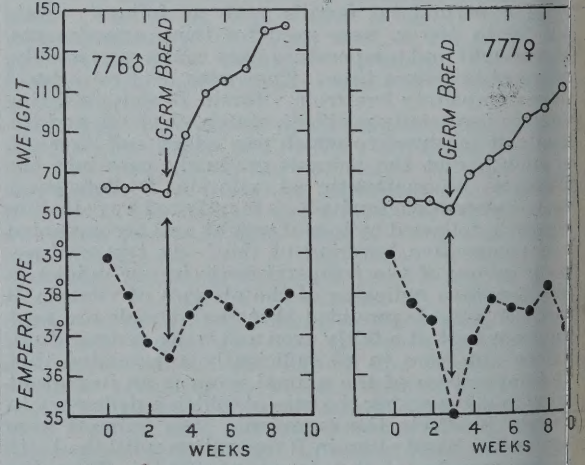
White bread ..	.. 25 to 50 g. = 250–500 %	of basal ration.
Wholemeal bread	.. 3 „ 6 g. = 30–60 %	
Hovis germ bread	.. 2 „ 4 g. = 20–40	

Since a rat of 100 g. weight only consumes about 10 g. of dried food material of a properly compounded ration, it is obvious that on a diet of which white bread is the only source of vitamin B it cannot obtain a sufficient amount of vitamin B to maintain its health. This is confirmed when tested experimentally. Rats were kept on the basal ration free from vitamin B. The addition of 2 g. of air-dried Hovis germ bread or of 3·5 to 4 g. of wholemeal bread was sufficient to ensure complete recovery. The addition of 5 g. of air-dried white bread (50 per cent. of the diet) or the substitution of bread for casein (100 per cent. of the basal ration) was unable to effect recovery and the rats died. A large number of each experiment have been carried out. The results are consistent in showing that the vitamin B content of any particular kind of bread as determined directly by feeding experiments corresponds closely to that evaluated by the calculation given above. Therefore, if it is known what relative amounts of the different milling products any particular bread contains, and if these milling products have not been subjected to any process which destroys their vitamin B content, it is possible to evaluate the vitamin B content of the bread from the data given above.

It seemed of interest to compare the vitamin B content of various kinds of "brown bread" sold under different names. Their methods of manufacture were unknown to us. These "brown breads" were found to differ widely. Some of them were about as rich in vitamin B as wholemeal bread. One particular form of "brown" bread was found to be poor in vitamin B. We merely mention this in order to bring out the point that the "brownness" of bread is not a measure of its content in vitamin B.

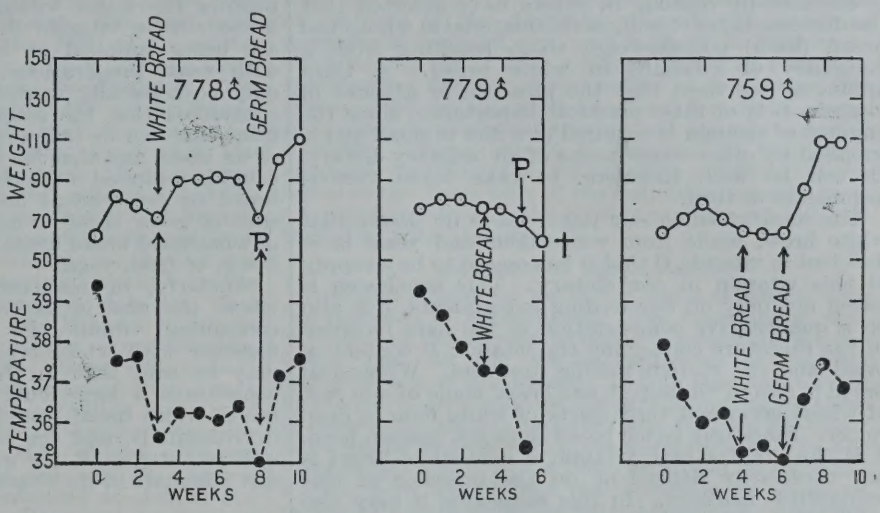
We have already mentioned that the introduction of roller mills probably brought about a material change in the dietetic habits of the population, by removing one of the main supplies of that vitamin from the diet. It seemed of importance to test this point by estimating the vitamin B content of bread made from stone-milled flour. Accordingly, flour stone-milled according to the old process was prepared for us in two different grades of fineness—namely, 56 per cent. extraction and 50 per cent. extraction. The 56 per cent. extracted stone-milled flour was found to be rich in vitamin B, 3 g. being sufficient to ensure recovery when added to a vitamin B free basal ration. The 50 per cent. extracted stone-milled flour was less abundant in vitamin B; 4 g. of this flour (40 per cent. of diet) led to only incomplete recovery. The minimal amount necessary to ensure complete recovery could not be determined as only a small amount of the flour was available. These experiments are sufficient to show that the introduction of roller mills did bring about an important dietetic change.

It is clear from what has been said that white bread is an article of diet practically free from vitamin B. The same conclusion is arrived at whether the vitamin content is determined directly by feeding experiments or whether it is calculated from the



The charts have been selected from a large number of experiments as illustrating the vitamin B content of white bread, germ bread, and of wholemeal biscuits (made without yeast). The experiment with biscuits is given as an illustration of the unimportance of yeast as a source of vitamin B in bread. The germ bread used was Hovis bread. The clear circles represent the weights of the animals, the dark circles the temperatures. It should be noted that the first temperature reading is almost always too high, because the rat reacts to the unaccustomed handling by a slightly raised temperature. In every case the animals were placed for three weeks (first weeks with rat No. 759) on the basal ration free from vitamin B, which produced the typical effects (cessation of growth, fall in weight and temperature). Then the various kinds of air-dried bread (or biscuits) were added to the ration so that the bread represented 33 per cent. of the whole diet. The charts show immediate complete recovery with germ bread (Nos. 776 and 777), a somewhat slower recovery with wholemeal biscuits (Nos. 774 and 775), a continued decline with white bread (Nos. 778, 779, 759). Two rats of the last group developed paralysis of the hind legs (P.). Of these, one (No. 779) died, the other (No. 778) recovered rapidly when germ bread was substituted for white bread. A third rat (No. 759) did not develop paralysis, but was so ill that it would have died in the next few days if white bread had not been replaced by germ bread, which led to a rapid recovery.

nount of yeast present in the bread and the vitamin ntent of the yeast. Reference has already been ade to observations (Hartwell) which are supposed show that white bread contains a considerable nount of this vitamin and to the explanation given at white owes this vitamin B content to the yeast lded in the process of aking. It is obvious from nsiderations both of our vn and of previous obsertions on the relative nount of vitamin B in ast and in the different illing products of the heat grain that this exanation must necessarily erroneous. It is necesry, therefore, to consider e experimental evidence which Hartwell's consions are based. The ual method of testing for e presence of vitamin B to keep rats on a basal ion adequate in every ner respect but known be free from this amin, as evidenced by e well-known effects on wth and temperature, and to add the article of t to be tested to this basal ration. This is the thod adhered to in our experiments. Hartwell, wever, kept the animals from the beginning the experiment on a diet of white bread, butter t butter-fat), a salt mixture, and water. On s diet the rats increased in weight and so far as recorded evidence goes showed no obvious signs vitamin B deficiency. The temperature of the mals was not taken, but it is stated that they were re susceptible to cold. This experimental arrangent is obviously faulty because it does not provide any controls to show that vitamin B may not ve been supplied by the only other article of this t—namely, the butter. It has frequently been wn that butter may contain considerable amounts vitamin B. Moreover, Hartwell carried out one ies of experiments with bread made with baking wder, in which no yeast was added in the process baking. Since, according to Hartwell's contention, addition of yeast gives to white bread the relative h vitamin B content which she claims for it on the is of her experiment, baking-powder bread should very poor in this vitamin. But the rats kept on king-powder bread and butter showed good growth ich was only slightly less than that of rats kept on ter's bread, made with yeast, and butter. No lanation is given for this result. It is clear, refore, from her own experiment, that in Hartwell's t the main supply of vitamin B which enabled rats to grow came from the butter and not from various white breads tested by her. It is to be retted that on the basis of these faulty experints Prof. V. H. Mottram, in whose laboratory se experiments were carried out, should have olished in popular writings the erroneous statent that white bread contains an abundant supply vitamin B and is not greatly inferior in this respect wholemeal bread or germ bread, and that as the ult of this propaganda this error should have been ely accepted.



General Discussion.

he discussion on "white bread and brown bread" suffered as much from the uncritical enthusiasm he advocates of "brown bread" as from the faulty ements of the defenders of white bread. It has n suggested, for instance, that a lower grade of ling should be adopted. But what the miller has dered the baker can put together again, so that g patent flour as a basis any desired admixture of other vitamin B containing milling products of wheat grain can be used for baking. It must also be considered that flour containing any part of the germ does not keep well for any length of time and cannot therefore be shipped, transported, or stored in bulk, so that it is not adapted for the supply of countries with dense populations. A high grade of milling is therefore an economic necessity. The high grade of milling has the further advantage that after separating the germ, methods of treating it can now be employed which without destroying its vitamin B content greatly prolong its ability to keep without deterioration. There is lastly the question of taste. Bread is not eaten as a medicine but as a regular article of diet, and many people prefer white bread to "brown bread" on the ground of taste. This may be partly due to the fact that it is more troublesome to make a good loaf from wholemeal bread than from white flour and partly to the presence of bran in wholemeal bread. On the other hand, there are also people who, on the ground of taste alone, prefer "brown bread" to "white bread."

The question of taste cannot be discussed on scientific grounds. But the nutritive value of different kinds of bread can be so discussed if the discussion is based on accurate data. The nutritive value of bread depends on a number of factors such as the content and the nature of the proteins, the content in carbohydrate, inorganic salts and water, its digestibility, and on its vitamin content. Before the discoveries of the vitamins all the other factors mentioned above had been repeatedly and carefully examined, and data concerning them can be found in many text-books on food or dietetics (see, for instance, R. Hutchison, Cohnheim). Generally speaking, the most important difference between white bread and wholemeal bread has in the past been attributed to the presence in the latter of the bran, because it affects the digestibility of bread. By the term digestibility is meant the extent to which the proteins and carbohydrates of bread are absorbed from the intestinal canal. There is a general agreement that with wholemeal bread, on account of the bran which it contains, the absorption of protein is less complete than with white bread. The absorption of bread such as Hovis bread, which is made from germ and white flour, and which does not contain any bran is nearly as complete as that of white bread (Goodfellow). While on these grounds the presence of bran in wholemeal bread has been looked upon as a disadvantage clinicians have recommended in the past wholemeal bread for its laxative effect. This they have ascribed to the presence of the indigestible material in wholemeal bread which was supposed to act as a mechanical stimulus to peristalsis and to the absence of which in white bread they attributed the constipating effect of the latter.

The discovery of the vitamins has added a new factor to the discussion on the question of the nutritive value of the bread, and it is this new factor around

which the recent controversy has centred. The recent discussion has suffered from an inaccuracy of the experimental data concerning the vitamin B content of the different kinds of bread and from a confusion of issues. Some authors have denied that white bread is deficient in vitamin B, others have asserted that the disadvantages of indigestible material in wholemeal bread (bran) counterweigh those resulting from a deficiency of vitamins in white bread. A third argument has been that the presence or absence of vitamin B is of little practical importance, since the amount of vitamin B required in a diet is small and is supplied by other constituents of an ordinary dietary. It will be well, therefore, to take these various arguments in turn.

The data given in our paper leave no doubt that white bread made from white flour and yeast is so deficient in vitamin B that it has ceased to be a supply of this vitamin in our dietary. This conclusion is based not only on our feeding experiments, but also on a quantitative consideration of the data recorded in the literature concerning the vitamin B content of yeast and the various milling products. Wholemeal bread is rich in vitamin B, and bread made of one part of wheat germ and three parts of white flour is even richer. Since this latter bread does not contain bran, it is clear that a high vitamin B content of bread is not necessarily dependent on the presence of this indigestible material. In this connexion it may also be pointed out that the constipating effect of white bread is probably due to the absence of vitamin B and not to the absence of indigestible material which is supposed to act as a mechanical stimulus. We have shown previously (Cramer 1923, 1924) that substances rich in vitamin B have a laxative effect, while in the absence of this vitamin there is constipation. This has been confirmed by Gross. It is also shown in an experiment on a dog recorded by Karr, in which the weight of the fæces excreted fell from 59 g. to 46 g. on a diet free from vitamin B and rose suddenly on the addition of this vitamin to 90 g.

The last question, whether the deficiency of white bread in vitamin B constitutes a serious dietetic error, requires a more detailed consideration. Our previous experiments, as well as those of McCarrison, have shown that the amount of vitamins required by an organism to maintain it in good health is much greater than that necessary to prevent or to cure the so-called specific deficiency diseases. Even a partial deficiency of vitamins in the diet or "vitamin underfeeding," as we have called it, if lasting for any length of time impairs health, and if it falls on children prevents perfect development. Quite recently this view has been endorsed by the observations of other workers (see, for instance, Rowlands and Plimmer). The idea which prevailed previously that the non-appearance of beri-beri in a population is a guarantee that the diet contains an adequate amount of vitamin B is, therefore, erroneous. Our present knowledge of the mode of action of the vitamins suggests that they have a specific stimulating effect on the functional activity of certain tissues. There is, in fact, a close analogy between this specific stimulating function of vitamins and the function of hormones. There is a similar analogy between the varying degrees in the impairment of health due to an inadequate supply of these two groups of agents.

Now cereals represent one of the main supplies of vitamin B in the human dietary, and before the introduction of the roller mills the stone-milled flour did represent an important source of supply of this vitamin. White bread has ceased to fulfil this part. On a varied diet which includes milk, butter, eggs, porridge, potatoes, and other vegetables, the absence of vitamin B from bread may not be a serious defect. But the people who can afford such a diet do not eat much bread anyhow. It is among the poorer classes, and especially the children of the poorer classes, where bread represents the bulk of the daily diet, and where butter is replaced by margarine that the absence of vitamin B from white bread has to be considered as a serious dietetic defect. Reports of medical officers of health show that many of these children live on a diet composed of white bread, margarine, jam, and fish with perhaps some potatoes. Such a diet is certainly deficient in both vitamin A and B and could be made adequate as regards the latter vitamin by the consumption of bread rich in vitamin B. At present these children are being supplied at welfare centres and schools with yeast preparations, a procedure which is not only economically wasteful but also absurd if it is considered that the amount of these yeast preparations that can be taken is relatively small on account of its taste, and that far larger amounts of vitamin B could be supplied if the children were given wholemeal bread or germ bread instead of white bread. One slice of germ bread weighing an ounce or two slices of wholemeal bread contain about as much vitamin as 5–6 g. of fresh yeast.

Similarly, in institutions, boarding-schools, &c., where the diet is likely to be monotonous, bread containing vitamin B should always be offered together with white bread. As a practical rule, it may be said that in those conditions when bread constitutes a large bulk of the diet, the exclusive use of white bread would make the dietary deficient in vitamin B, and the partial substitution of bread rich in vitamin B for white bread would make the diet adequate in its vitamin B content.

Summary.

1. In accordance with the observations of previous observers, it was found that wheat germ is very rich in vitamin B. It is at least equal in that respect to yeast.

2. The various milling products of the wheat grain contain vitamin B in the following proportions, taking the vitamin B content of yeast = 100 :—

Germ	100	Bran	33
Middlings	50	Patent flour	0

3. The vitamin B content of different kinds of bread depends upon the milling products used in the making of bread. The vitamin B content of the amount of yeast added in the baking of bread is too small to be responsible for a significant addition to the vitamin B content of bread. The vitamin B content of different kinds of bread, as calculated from the amounts and the vitamin B content of the various milling products and yeast used in the making of the breads, corresponds closely to their vitamin B content as determined experimentally. Thus white bread made with yeast is very poor in vitamin B. Wholemeal bread and the germ bread examined by us are very rich in vitamin B. The latter differs from wholemeal bread in being free from bran, so that, contrary to what has been stated, richness in vitamin B is not necessarily dependent upon the presence of indigestible material.

4. The significance of these findings in relation to dietetics is discussed. It is pointed out that the nutritive value of different kinds of bread, if treated as a practical problem of dietetics, must be considered in relation to the diet as a whole. Where the constituents of the diet other than bread are poor in vitamin B the nutritive value of white bread is definitely inferior to that of bread rich in vitamin B.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Dentists Bill and "Treason."

THE Dentists Bill led to some warm debates last ek in committee in Dail Eireann. The first tussle ne over the proposal in the Bill which recites reason" as one of the offences for which the name a dentist may be erased from the Register. The etion of the clause was urged by Dr. Ryan (Fianna il), who was supported by Mr. De Valera and other mbers of their party. It was urged that the inition of treason was to a great extent a party tter, and that a respectable man who incurred the pleasure of the party in power might find himself victed of treason and permanently debarred from ctice as a dentist. On the other hand, the Governnt stood firm by their clause and backed by the bour Party and the Independent Members, they l a considerable majority. The Minister in charge the Bill, Mr. McGilligan, usually very accurate, de a blunder in defending the clause. He asked: id the Deputy think for one moment that a man victed of treason against the English State, and ased after being sentenced to death, would be wed to practise under the British Medical gister?" There is at least one case in which a n convicted of treason, sentenced to death, and ased, has become a registered medical practitioner hout let or hindrance. Moreover, a medical man nd guilty of treason in Dublin in 1916 and sentenced 20 years' imprisonment has continued to practise e his release some months later, and his name er was erased from the Medical Register. As a tter of fact the word "treason" does not occur the Medical Acts, although, as Mr. McGilligan ated out, the offence is no doubt adequately ered by the term "felony."

discussion of more immediate interest to medical n was concerned with the proposal in the Bill to hibit any dental work being done by medical ctitioners except in urgent cases. The clause was cked by Sir James Craig, Dr. T. Hennessy, and t of the medical deputies on both sides of the use. The impossibility of making the clause ctive in country practice without grave hardship the poor was stressed by several speakers, and nately the Minister agreed to the deletion of the se. He added, however, that it might be necessary, later stage, to introduce another amendment to ten up the section.

Abolition of Workhouses.

he recommendations of the Commission on Local ernment in Northern Ireland, briefly summarised THE LANCET of Nov. 12th (p. 1041) include the lition of workhouses. There are at present workhouses in Northern Ireland, most of them empty or more than half empty. One of the t pleasing features of the evidence given before Commission was that it showed the gradual disearance of destitution from Northern Ireland. existing workhouses could with great advantage, ally and economically, be replaced by a limited ber of county homes (perhaps three in all for the area) where the conditions of life would be much more comfortable and home-like than is possible in the existing workhouses. Able-bodied persons admitted to county homes should be subject to strict discipline and employed in useful work in connexion with the home. The Commission recommends that all children of the destitute class should, as far as possible, be boarded out, and that all limitations to the boarding out of such children should be removed. It suggests a number of regulations to secure that this system shall be on sound lines and free from abuse. It is recommended that tramps and casuals requiring a night's lodging should be directed to the police barracks, and that the police, after satisfying themselves of the bona fides of the individual, should issue a recommendation to the relieving officer, who should then deal with the case.

Treatment of Tuberculosis.

Another section of the report deals at length with the question of tuberculosis. The Commission considered that the present methods of treatment are too costly and on the whole ineffective as regards stamping out of the disease. It held that sanatorium treatment is only suitable for early cases where there is reasonable hope of recovery and that all advanced cases should be dealt with in other institutions. Two or three sanatoriums, it was thought, would be sufficient for Northern Ireland, and that provision for advanced cases might be made in the district hospitals. The view was expressed that advanced cases are the most infectious and are unsuitable for domiciliary treatment. The Commission recognised the great value of sanatoriums as educative agencies for patients and for the public generally. The lack of institutional treatment for non-pulmonary forms of tuberculosis was emphasised, the only institution for this purpose in the area being the Graymount Hospital for Children. The adoption of the Tuberculosis Acts is at present permissive, and the Commission held that they should be made obligatory on all county health committees.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Cripples.

SOME time ago a committee was formed in Edinburgh to consider the establishment of a special hospital for cripples. The earliest conference decided that a central orthopædic hospital should be built on the outskirts of Edinburgh; that major clinics should be formed in the more populous centres of the counties; that minor clinics should be formed in the remoter parts; and that coöperation between existing hospitals and the new central orthopædic hospital was essential. Steps were taken to collect funds, the sum aimed at being £75,000. Everybody in the movement agrees that a special hospital is the only means of dealing efficiently with the complicated group of problems covered by the term "cripple." Many small organisations have been working for years and have done good work, but the range of orthopædics has rapidly developed. The education authorities have been obliged to make certain provision in schools for physical defectives, but the deformities of growth are themselves a host, and the value of electricity, massage, ultra-violet light, hydrotherapeutics, remedial gymnastics, and their combinations is only beginning to be understood. The work is far beyond what any "acute" hospital can undertake, for time is the essence of the treatment. The projected hospital will certainly not want for cases. It is understood that the Scottish Board of Health are ready to consider this new development as a part of the child welfare and school schemes, and to judge by the favourable local reception, the committee should soon raise enough to justify them in proceeding with site and plans.

Administrative Lacunæ.

At a meeting of the Medico-Chirurgical Society of Edinburgh, held on Nov. 2nd, when the new President,

Dr. Logan Turner, took the chair, a paper on the scheme was read by Prof. John Fraser. It was agreed, he said, that the term "cripple" should not include the blind, the deaf mute, or the mentally defective, but should comprise all children below the age of 16 whose affliction was capable of remedy. It was difficult to say how many cripples of this class there were in South-East Scotland, but the Scottish Board of Health had estimated that there were 753 in the five groups: severe rickets, tuberculous disease of bones and joints, poliomyelitis, and congenital and other crippling deformities. Legislative machinery already existed for the treatment of cripples, whatever their malady, up to the age of 5, but later only such conditions as tuberculosis and infantile paralysis were provided for. Child welfare centres had to refer cases to special or general hospitals, and something under a hundred beds were available for their accommodation. This was quite inadequate. The type of institution required must be built to provide sun, wind, and fresh air. Further treatment might be for a long period combined with education of the patient, and later continued at home. Cripple homes were not a solution as no treatment was provided. The present scheme aimed at seeking the cripple in the earliest state and at following him until he was restored to well-being and efficiency, so far as was humanly possible. Minor clinics would be on out-patient lines and would be situated in small towns or villages and attended by a nurse who could apply appropriate massage and splinting under the supervision of local practitioners. These centres would be visited regularly by a central orthopædist. Record cards would be made of all cases; these would be available to the family doctor and health authorities. The major clinics were intended to be part of the general hospitals of towns and more specialised treatment could be carried out in them. Central orthopædists would visit and collaborate with the hospital staffs. The new Edinburgh hospital, said Prof. Fraser, would be built on the outskirts of the city and would take 75 patients. Among the speakers who discussed the paper was Miss Gertrude Herzfeld, who, speaking as a surgeon of a children's hospital, said that the scheme would be useful for all after-treatment, but thought that all the cases should first come, as they do at present, to the children's hospital, where initial treatment should be carried out.

Hospital Coördination.

The relative position of the voluntary and other hospitals was referred to recently by Sir John Gilmour, Secretary of State for Scotland, in a speech at Falkirk. He laid down the fundamental proposition that any scheme which did not utilise to the full the available resources of existing hospitals required overhauling, and commended the kind of solution to this difficulty which was being observed in the Aberdeen area, where the Poor-law authority had handed over its hospital to be administered by the city of Aberdeen and where there was a complete and cordial coöperation between the voluntary hospitals in the training of nurses and University students.

Of the £400,000 aimed at for the new Royal Infirmary, Aberdeen, a sum approaching £260,000 has already been subscribed.

NOTES FROM INDIA.

(BY OUR OWN CORRESPONDENT.)

Tropical Medicine Congress in Calcutta.

As your readers will be aware by this time the Government of India has invited the Far Eastern Association of Tropical Medicine to hold its Seventh Congress in Calcutta next month. All Calcutta is athrob with excitement and pleasure at the prospect of welcoming so many distinguished visitors. Many scientific sections and demonstrations have been arranged, all devised to stimulate us to deeper investigation of hitherto unexplored regions of the principles and practice of medicine in the tropics. Short tours have been planned to places of interest in Calcutta and throughout India, and no effort is being spared by the Calcutta Local Committee to afford every Congress delegate a pleasant memory of his visit to India.

Public Health Policy.

One may hope that the Congress will do something to arouse the national consciousness of India towards a considered health policy. The Reforms Act of 1919 relegated public health to the care of provincial governments. In 1926 the Government of India held that the general direction of a policy of public health must remain in its own hands, on the grounds that considerations of public health should permeate all fundamental legislation and receive a definite place in the administration. At present, instead of a clear pronouncement from a central responsible government we have merely a number of provincial authorities in charge of the health of India, with the result that the public health executive is at the mercy of local politics. Until the political horizon clears there will be little improvement in dealing with the public health problem.

The Calcutta Medical Degree.

The same policy of relegating to provincial control the details of medical education—the standard of education being still presumably with the central government—led in 1925 to misunderstandings with regard to the recognition of the Calcutta M.B. examination by the General Medical Council. It is greatly to the honour of the Council, guided by the prudent and temperate report of Sir Norman Walker after his inspection of the affiliated colleges and the examinations, that they made the first move in rapprochement and have expressed a willingness to consider any application for renewal of recognition from Calcutta University, provided that the new regulations be immediately introduced in the early years of the curriculum. The University authorities having agreed to this, it is hoped that Calcutta graduates will be enabled to prosecute further studies in England and to obtain higher degrees without having to appear before any of the home examining boards. The Medical College of Calcutta especially felt this loss of recognition keenly, founded as it was in 1825, 20 years before any other medical school or college in which instruction in the preliminary medical sciences was provided side by side with clinical teaching; and its examinations at the conclusion of the curriculum included the three branches of medicine, surgery, and midwifery. What a striking testimony to the foresight and sagacity of the medical officers of the Honourable East India Company.

Pure Food and Drugs.

India stands in great need of legislation for ensuring the purity of its food and drugs. That the cult of quackery prevails in every branch of medical and surgical science is readily seen from the multitude of advertisements in every vernacular paper. Manufacturers and vendors of counterfeit drugs and chemicals are legion. At present they can only be prosecuted in a civil court at great expense and loss of time. To render such transgressions criminal will require a Food and Drugs Act. But under the new régime this is a matter for each individual province, and it is to be feared that there will be considerable delay before India falls into line with the usages of other countries under the League of Nations in this respect.

Scientific or Empirical Treatment?

A storm has arisen among the indigenous medical practitioners over the statement made by Mr. T. Pilcher, M.P. for Falmouth, in which he is reported to have said that "at the clamour of the Indian politicians, the Government of India has been forced to give State aid to the preposterous Ayurvedic and Yunani systems of medicine prevalent throughout the country." The practitioners of the former system claim that a modification of Ayurvedic medicines is more suitable to the needs of India than the imported

oreign scientific system. It is true that religion and ntiquity venerate Ayurveda, but it is clear that only o long as scientific education in India remains at its resent low level can a purely empirical system of reatment prevail and then only among the less nlightened.

Beri-beri and Epidemic Dropsy.

The question of the ætiology of beri-beri has come gain to the fore by reason of the recrudescence of the isease in Madras and Calcutta and in many rural reas. Urgent requests for a committee of investiga- ion have now been made to local governments. The isease known as epidemic dropsy which, having died ut in 1890, again appeared in 1907 and is now epidemic ach year in one or other district in Bengal, has still o be clearly defined in its relation to beri-beri. Vell-organised investigation might definitely establish ie ætiology of both.

Public Health Services.

MENTAL HOSPITAL REPORTS.

Devon Mental Hospital at Exminster, at the id of 1926, had 1227 patients on its registers. The neral recovery-rate was 35·53 per cent., but the ure for the private patients works out at 69·8 per nt. for a total of 294 admissions. The death-rate r this year was 9·17 per cent. The increase on last ar's low figure of 6·6 per cent. is chiefly due to cases of pneumonia, for some of which the coal strictions were undoubtedly responsible. No deaths curred from typhoid, and only two from enteritis. utopsy was performed on 69 per cent. of the patients no died, an absolute increase of 26 operations. No dsores at all were reported throughout the year. ie incidence of tuberculosis is still somewhat high, patients being isolated. The hospital has always been oubled with sporadic typhoid, and in the autumn 1924 preventive inoculations were introduced, since ien only one patient has been suspected of the sease. Even in this case all cultures were negative. idal tests have also shown the efficacy of the oculations. The drainage system has been tested d will doubtless be set in order at once. The edical superintendent speaks with caution about e results of malaria treatment in 13 cases of general ralysis. Three died of intercurrent affections, one s been discharged and remains well, two are con- erably improved, and the remaining seven slightly proved. The figures contain a promise which is nfirmed by the results obtained by others, that this thod gives some beneficial results in nearly all ses. The consulting surgeon made 60 examinations d performed 10 major operations, most of which ulted in great mental improvement; cholecystec- ny and the relief of a strangulated hernia respectively abled two patients to take their discharge. The diologist examined 60 patients, and his work has en much facilitated by the provision of a 10 K.V.A. h-tension transformer. An ophthalmic consultant ends monthly and examined 61 cases during 1926, ding a considerable amount of chronic disease ing from before admission. The dental record ludes 425 examinations, 117 extractions, and dressings and fillings. The aggregate number of ients and staff which has received benefit from consultants' services is 300. A fortnightly out- ient clinic is maintained in Exeter, and the perintendent pleads for facilities for bed-treatment al psychotherapy. 124 patients have been on parole ly within the walls and 45 have been given extended vileges; only four cases of abuse have occurred. ere are now 11 open wards, allowing free entrance al exit to 270 patients, and open single rooms are be provided and allotted as a privilege. The list of icles manufactured by patients is impressive. All stationery, including the annual report, is printed he institution, and patients are employed in book- ding, weaving, mat-making, net-making, upholster- ing, shoe-making, sewing, and knitting. Nearly all earthenware utensils have now been replaced by aluminium. The patients' play is as varied and as well organised as their work. Two additional loud-speakers have been purchased and programmes can be reproduced, by an ingenious use of the house-telephone system, at any point or points where they are required. Among new improvements are a verandah to the female receiving ward, a dwelling-house which was purchased as a home for private patients and which now accommodates 30 nurses, and an ultra-violet light apparatus. Clinical rooms are now attached to all but three of the wards and a sheltered gallery has been built opening out of the men's infirmary. The laboratory staff made 1440 investigations. Thirteen nurses passed the final and 13 the preliminary M.P.A. examinations. Female nurses have now been posted in the isolation hospital and male infirmary, and are proving a success. The report of the Visiting Commissioners indicates that the diet might be revised with advantage, and points out the need, in conjunction with the operating theatre, of sterilising, waiting and surgeons' rooms. The annual report is illustrated with two excellent photographs and does credit to the hospital printers.

Dorset Mental Hospital.—On the last day of December, 1926, 902 patients remained—an increase of 35 for the year. Of the direct admissions 31·61 per cent. were discharged fully recovered, and the death-rate has fallen to 5 per cent. from 5·5 per cent. last year and 8·2 in 1923. Post-mortem examinations were held in 52 per cent. of the deaths. For the first time in at least nine years no dysentery or typhoid was experienced, but five carriers are still in the hospital. There was no other epidemic sickness. Ten patients are under treatment for pulmonary tuberculosis. The consulting dental surgeon, who visits fortnightly, examined 276 patients. Additions to the hospital include a solarium in course of construction and a chlorinating plant; an out-patient clinic is held weekly in Dorchester. Ten patients were sent out on trial; 62 had extended parole and 27 restricted parole. The vacancies on the male side were 99, but there was one female inmate over the establishment. An operating room is nearly completed and a dental room is in use. The male admission ward has been rearranged and now has its own verandah and is to have its own continuous bath. The total number of routine examinations performed in the laboratory was 536, and 216 tests were undertaken in the search for typhoid carriers. The Boltz test is carried out on all cerebro-spinal fluids and is invariably negative in psychoses and positive in general paralysis. Tryparsamide has been used in the treatment of five general paralytics; one was discharged recovered, two were greatly improved, and two advanced cases failed to benefit. The improvement showed itself chiefly in the gait, speech, and mental condition. A research into the records of male patients for the past 40 years established that extraverts develop syntonic and introverts schizoid types of psychoses. Fifteen male and 14 female nurses are certificated or registered; ten nurses passed the preliminary and 13 the final M.P.A. examination during the year. The Commissioners recognise the need for an admission hospital, without which they say that no mental institution can be considered to be equipped in accordance with modern ideas.

Kent County Mental Hospital at Barming Heath, Maidstone, showed a total of 1855 residents at the end of 1926, as against 1793 at the beginning. There are vacancies for 19 males, but the female population is 58 in excess. The death-rate, 5·1 per cent., is the lowest yet recorded, and autopsy was performed on 95·8 per cent. of the cases. The recovery-rate was 34·4 per cent., somewhat below the average owing to the low rate of 22·9 per cent. on the male side; no zymotic disease occurred. Malarial treatment for general paralysis is to be resumed and a solarium has been built for recent male cases. Sixty-seven patients had parole outside the walls and 140 inside; 65 were allowed out on trial and 24 of these received money

allowances. Many wards have open doors. 67 per cent. of patients are now occupied, and the occupation officer has taken over the direction of the tailoring and boot-making shops. An occupational treatment room has been started for noisy patients. The Visiting Commissioners praised the high standard maintained by the staff and the well-organised system of training that exists here. Out of 178 nurses 74 are certificated or registered, and 35 have passed the preliminary examination. The Commissioners especially remarked on the quietness of the wards at night.

Chartham Down, near Canterbury, the other Kent hospital, houses 1228 patients, 46 more than last year. The superintendent and the Commissioners regret the influx of young mental defectives, a trouble not confined to this institution. The death-rate was 8 per cent. and the recovery-rate 32 per cent.; 67 per cent. of the deaths were verified by autopsy. The general health was satisfactory, as only slight influenza and no dysentery were reported. The disease incidence appeared high on account of the admission of ten persons with active tuberculosis. An X ray outfit is being installed, and the whole building is now lighted by its own electrical plant. Results of the Starke method in general paralysis, and of luminal in epilepsy, have been favourable. Parole is allowed to 46 patients outside the estate and 86 within; some of the wards are "open door" and some carry the privilege of sitting up after the usual retiring hour. The hot-water supply has been improved and plenty of hot water is now available, but the ward heating remains erratic and extravagant. The sanatorium has been turned into quarters for 30 nurses. Fifty-two out of the 146 nurses are registered or have certificates.

Brighton County Borough Mental Hospital at Hayward's Heath shows an increase of six in its population, the total at the end of 1926 being 834. Except for 16 cases of chronic tuberculosis, three exanthemata, and a few minor accidents, the general health has been excellent. The death-rate was 7·5 per cent. with post-mortem examination in 76 per cent. of cases, and the recovery-rate was as high as 48·9 per cent. Vaccine treatment has been tried and gave good results in one case of acute mania with hallucinations, who was removed somewhat prematurely after nine weeks but has remained well. Of five general paralytics sent elsewhere for malarial treatment one has returned much improved, three are reported as improving, and one is unchanged. The dental surgeon examined 570 patients, and an operating theatre and pathological laboratory are being constructed. The weekly clinic in Brighton treated 99 patients. Only 16 per cent. of the patients discharged were sent out on a previous trial, and the Commissioner urges in his report an extension both of this measure and of the granting of money allowances, which were given only in four cases. Parole is given to 80 inmates, of whom 33 are allowed outside the grounds, and one ward on each side has open doors. Additions to the building include a clinical room, a sewing room, and a waiting-room, but it appears that verandahs are still badly needed. Week-end leave was granted on 36 occasions and absence for the day with friends on 55. Patients attend the pictures locally and in Brighton, and local cricket and football matches and fêtes. The dietary has been improved in quality and variety. 57 per cent. of the male and 30 per cent. of the female nurses now hold certificates.

West Sussex County Mental Hospital, Chichester.—Here 779 patients were under treatment at the end of 1926, 31 more than at the end of 1925. The death-rate was low, 5·15 per cent., and the recovery-rate 36·15 per cent. An influenza epidemic broke out early in 1927, but except for one case of paratyphoid and one of chicken-pox the hospital was free from infectious disease in 1926. A dental surgeon visits fortnightly, and three other consultants are retained. Forty-six patients were allowed out on trial during last year; 17 were given outside and 55 inside parole. The new water-softening plant should make for comfort and economy. Nine nurses passed the preliminary and seven the final M.P.A. examination, while two passed the G.N.C. preliminary and one the fi The committee recognise the imminent necessity increasing the accommodation for female patients

Hertfordshire County Mental Hospital at H End, St. Albans, now shelters 952 patients, 48 m than last year's population. The recovery-rate v 25·3 per cent. and the death-rate was 5·48 per ce as against 6·52 per cent. in 1925. Autopsies were h in 42 out of 51 deaths. Thirteen cases of intes disease and 11 of tuberculosis were notified, toget with one of diphtheria and two of erysipelas; th was also an outbreak of influenza. The den treated 186 patients, and the surgeon perfor several major operations. The system of parole being extended, and one ward on the male side open doors. Nine nurses passed the prelimin M.P.A. test and two gained the certificate, bringing numbers so qualified up to 35 and 38 respectiv The Commissioners, in their report made in Ju commented on the overcrowding on the female s and on the poor dietary.

City of Birmingham Mental Hospital, Win Green.—The numbers at the end of 1926 were 7 an increase of 13 during the year and an exc of 32 on the authorised accommodation. 355 Birmi ham patients are boarded out with other authorit and fresh accommodation is urgently needed. death-rate, 7·2 per cent., was the lowest in the hist of the hospital since 1850, and post-mortem exami tions were made in 65 per cent. of the deaths; recovery-rate was 30·7 per cent. of the direct adm sions, or, including "relieved" cases, 46·5 per ce Fifty-five out of the 70 patients discharged recovered, and 15 of those discharged as relieved, w allowed out on a month's trial first and maintena or help was given to 40. Nine cases of colitis with deaths occurred in the autumn and two cases pneumonia were notified; seven patients suffe from pulmonary tuberculosis, of whom four d Otherwise the general health was good. Rec admissions are inspected by the visiting dentist, rhinologist, and on the female side by the gyna logist for foci of sepsis, and the results have been v hopeful. Of four cases of general paralysis trea with induced malaria one recovered enough to ret to work, one was improved, and two showed change. In addition to the services of the visit staff the hospital possesses a special treatment bl with operation, anæsthetic, sterilising, electrothera hydrotherapy, and surgeons' and patients' rooms w sanitary accommodation. Parole is being given more patients than before, and has only been abu twice during the year. Selected male patients w taken to the canal for fishing, and female patients outings in the neighbouring hills. 63 per cent. of inmates were usefully employed, the men at t trades or in the gardens and the women on the w of the institution. The clinical rooms have b refitted and modernised.

The sister establishment at *Rubery Hill and Ho moor* housed 1459 patients, 7 more than in 1925, boarded out 320 under contract; this arrange secured 42 vacancies, 18 more than were ever fi during the year. In spite of the bad health of m of the new admissions the death-rate was c 5·67 per cent., on 52·4 per cent. of which autopsy performed. The recovery-rate was 40·1 per cent the direct admissions, with 13·4 per cent. m discharged relieved. Infective disease was sli Six patients were being treated at the end of the y for tuberculosis, two nurses caught scarlatina fr outside, and two cases arose of erysipelatoid infect from deeper tissues. There was no intestinal dise and the average health was good. Large quantitie typhoid vaccine have been used for non-spec protein therapy, and this should increase the gen immunity. General paralysis has been intensiv studied, and pyrexial methods, including malaria protein therapy and combined with removal of se foci and specific treatment, have given varying hopeful results. A bulwark of treatment is concerted attack on focal sepsis in every patient

team of visiting surgical specialists. A mercury-our lamp has been added to the special treatment k, which includes theatre, electro- and hydro-rapy room, dark room, and rooms for surgeons and ients. 391 male and 435 female patients are fully employed. Parole is granted on and off the te, and many improving patients are given week-s with their friends by way of preparation for harge. The cinematograph, films for which are plied by a private donor, is much appreciated. nurses hold the M.P.A. certificate, 26 of whom ed it in 1926. Forty-two passed the preliminary nination during that year. The committee now rd their hospitals at Winson Green and Rubery , with the annexe at Hollymoor, as one hospital er the control of Dr. T. C. Graves, with the title hief medical officer. The divisions will each be harge of a medical superintendent.

Hafford Mental Hospital showed an increase of atients, from 961 to 996, during last year, and is ously overcrowded on the male side. Like all r superintendents, Dr. B. H. Shaw pleads for the er staffing of vacant Poor-law accommodation, the disposal of mental defectives in special insti-ns. The death-rate was 7·42 per cent., and the very-rate 28·74 per cent. for men and 21·74 per cent. women. There has been no zymotic disease for years. A dentist visits fortnightly and an ultra-t apparatus has been installed. Figures for the 100 cases discharged recovered showed that the th's provisional treatment suggested by the al Commission would have been quite inadequate 8, but that 58 need never have been certified if could have had six months' voluntary treatment. superintendent deprecates the scheme of sending patients to a receiving house from which they soon be moved, and points out the shortcomings neral hospitals in the treatment of mental disease ; lvocates an extension of the voluntary system to c institutions. The committee recognise the t necessity for a separate admission hospital. mmodious verandah annexe is being built for male culous patients. In all there are 17 tuberculous nts, for whom there is as yet no special provision. pt for the isolation hospital and a villa the whole ution now has electric light. In addition to its ary work the pathological department is investi-g the diagnostic possibilities of cobra venom, the , of ultra-violet rays, and certain symptoms able to the basal ganglia occurring in dementia x and encephalitis lethargica. No women s are employed on the male side. Sixty-one of aff are registered or certificated.

e population of *Burntwood Mental Hospital*, rdshire, was 936 on Dec. 31st, 1926, an increase ; death-rate for the year was 7·85 per cent. and ery-rate 25·94 per cent. Eight deaths occurred g an epidemic of dysentery which affected tients on the male side. Two cases of general ysis were treated with malaria and both were arged ; one is known to have been at work for onths. A dentist visits regularly. Twenty-eight ts, or one-third of the number discharged, were ent out on trial, 16 of these receiving an allow-

The introduction of a coke-oven, a Hobart , and a potato and fish frier into the kitchen has lerably improved the dietary, but the Commis-s would have liked to see more interest taken creation. More nurses are sitting for their cates, and the number certified or registered is 1. Sixteen have passed their preliminary tests. committee, foreseeing fresh demands on their modation, are pressing for the addition of an sion hospital and convalescent villa. At present ases are admitted into the sick wards, where they imes come in contact with troublesome patients.

Cddleton, the third of the Staffordshire county al hospitals, had 1122 patients in its wards at the last year ; this is one less than the year before. utmost capacity of the building, estimated on irement, is 1127, and overcrowding is acute, in of boarding-out. The admissions were 290, of whom only 76 could be considered recoverable, and this fact is considered by the medical superintendent a weighty argument against building an admission hospital of 50 beds. He advocates an "acute" hospital of 150 beds, with the special treatment block attached ; no recoverable case need then go to the main block nor irrecoverable to the hospital, and no resentment would be incurred among relatives. The death-rate, 6·96 per cent., included 7 deaths from dysentery, 50 cases of which occurred throughout the year, entailing much laboratory work and handicapping research ; 15 of these were children. Fifteen of the 19 carriers were children, many of them from guardians' institutions, and these were fairly certainly responsible for the size of the epidemic. None of them died. No advance in treatment, remarks the superintendent, has been made beyond magnesium sulphate ; when it fails nothing will cure, probably because of secondary infection. The recovery-rate, calculated on the total admissions, was 23·1 per cent. Almost 40 per cent. of the discharges were made under Section 79, but 17 patients only were allowed out on trial, of whom nine received money grants. This hospital accommodates 90 mentally defective children in three wards, and more room is badly needed. The dental surgeon now visits twice a week. Ultra-violet radiation is being introduced and may reduce the present high incidence of tuberculosis ; general paralysis is treated with induced malaria. Although no special occupation officer is employed, no less than 40 per cent. of the male patients are employed on the farm and 26 per cent. of women in the laundry. 32 per cent. are taken for walks beyond the estate, 33 per cent. attend the weekly entertainments, and 40 per cent. go to church. In spite of the poor soil the farm is worked energetically, and the superintendent's report contains much technical matter and a scheme for scientific farming in the future. Although qualified nurses are less difficult to find than they were, shortage of accommodation is still a handicap. Recent improvements include a supplemental water-supply, a cinema, and a class-room in the children's ward. Cheddleton possesses one of the best and largest bands of the mental hospitals of the country, trained by the superintendent.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 5TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week :—Small-pox, 219 (last week 199) ; scarlet fever, 2341 ; diphtheria, 1482 ; enteric fever, 89 ; pneumonia, 1098 ; puerperal fever, 39 ; puerperal pyrexia, 94 ; cerebro-spinal fever, 10 ; acute poliomyelitis, 29 ; acute polio-encephalitis, 1 ; encephalitis lethargica, 26 ; continued fever, 1 ; dysentery, 10 ; ophthalmia neonatorum, 91. There was no case of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 5 (2) from enteric fever, 19 (2) from measles, 8 (2) from scarlet fever, 11 (2) from whooping-cough, 34 (9) from diphtheria, 64 (13) from diarrhœa and enteritis under two years, and 86 (21) from influenza. The figures in parentheses are those for London itself. The number of stillbirths registered during the week was 210 in the great towns, including 32 in London.

SOUTH LONDON HOSPITAL FOR WOMEN.—This hospital, on Clapham Common, is in urgent need of enlargement. Attendances in the out-patients' department average 36,000 annually, and the waiting list never falls below 500. Upon a 2-acre space at the rear of the buildings it is proposed to build a new out-patients' department, to increase the accommodation to 200 beds, and to provide better quarters for the nursing staff. The scheme will cost £180,000, £65,000 of which is required for the out-patients' department, towards which the King's Fund has promised £3250 conditionally upon this part of the undertaking being opened free of debt.

"Audi alteram partem."

MEDICAL PRIVILEGE.

To the Editor of THE LANCET.

SIR,—Your leading article upon the effects of the McCardie judgment in July last gave weighty expression to the feelings of consternation amongst medical men at the prospect of being compelled to betray the solemn trust of their patients at the order of a judge. Since resumption of Parliament I have had the opportunity of conversation with some leading counsel in the House of Commons, and I have received from them very considerable encouragement for the suggestion that I should ask, under the 10-minutes rule, leave to introduce a Bill securing, as the *minimum* concession, privilege from disclosure for communications made by patients to medical practitioners in pursuance of Article II. (2) of the Public Health (Venereal Diseases) Regulations, 1916. I have obtained leave for a motion, which is now upon the Order Paper for Tuesday, Nov. 22nd, to introduce a Bill, as follows: "Medical Practitioners' Communications Privilege,—Bill to provide that certain communications between medical practitioners and their patients shall be privileged from disclosure in evidence," and I am promised the support of a number of very distinguished lawyers in the House for a Bill securing privilege restricted to the special case of venereal diseases. I should, of course, have preferred unrestricted privilege, and a clause which I had proposed to incorporate in my Bill ran as follows: "Confidential communications passing between a medical practitioner and his patient shall be privileged from disclosure where made for the purpose of obtaining or giving medical assistance in some illness from which the patient is suffering." I am, however, being earnestly dissuaded from attempting this wider purpose by distinguished lawyers in the House who warn me quite frankly that there would probably be general opposition from lawyers to the enlargement of medical privilege to the same degree as the lawyers now enjoy. If your readers can in any way assist, by representations to their Members of Parliament, the acceptance of my motion on Tuesday, the 22nd, the crying scandal of the present position—namely, the conflict between law and regulations in relation to the administration of clinics for venereal diseases might perhaps be removed.—I am, Sir, yours faithfully,

E. GRAHAM LITTLE.

House of Commons, Nov. 14th, 1927.

FINANCIAL HELP FOR DENTAL STUDENTS.

To the Editor of THE LANCET.

SIR,—From time to time, in my capacity as Registrar of the General Medical Council, I am asked whether I know of any fund from which the sons or dependents of medical men can receive financial assistance to enter the medical profession, and my reply has to be that some of the medical schools have scholarships for this purpose, but, apart from this, I do not know of any fund from which they can be assisted.

With regard to dentistry, however, the position is different. Unless the entry of students to the dental profession is increased it is not improbable that in process of time there may be a shortage of dentists to attend to the needs of the public. In suitable cases, therefore, in which the requirements of the General Medical Council for the registration of students have been satisfied, the Board is prepared to give financial assistance, by means of bursaries, to pay the cost of fees and instruments, and in some cases maintenance is given in addition. So far as I know there is scarcely any other great profession for the entrance of which such facilities are provided. As it is possible t medical practitioners may know of cases in wh young men, in every way suitable for entering profession of dentistry, are debarred from so doing lack of means, it is desirable that the assistance offe by the Dental Board should be made known.

Further information will gladly be sent on appl tion to this office. All letters should be addressed the Registrar of the Dental Board.

I am, Sir, yours faithfully,

NORMAN C. KIN

44, Hallam-street, London, W., Nov. 10th, 1927.

THE AUSCULTATORY "SILENT GAP."

To the Editor of THE LANCET.

SIR,—I agree with what Dr. Gibson says in interesting article on the above subject about little attention paid in this country to the wor French observers. But from the context I fai gather that Dr. Gibson, though quoting Barb "La Méthode Auscultatoire," has noticed his expl tion of how the arterial sounds are produced. Tes his explanation with the abundant clinical mat afforded by the Heart Clinic of the Ministry Pensions I have found it very illuminating.

In listening to the sounds Barbier recommends observer to concentrate his attention on the varia in loudness which follow a regular sequence from systolic to below the diastolic levels. The varia in tone have led to the formation by observe zones which are a needless complexity. The varia in tone are hardly ever alike, but the variatio loudness follow the same course in nearly all c The first sound heard as the pressure is released dull thud or hiss which denotes the systolic l This, increasing rapidly in loudness, reaches maximum about 5 mm. lower and then grad becomes fainter, but about 15 mm. lower it wi noticed to be increasing in loudness, but gradually, so that it will be about 30 mm. lower the arterial sound is louder than in any other pa the curve. Then it suddenly becomes quite f thus determining the diastolic level.

Barbier holds that there are two factors at w vibrations in the blood stream and vibrations i arterial wall. The sounds in the first part o curve are mostly blood stream sounds which dim as the lumen of the compressed artery is allow open. The sounds in the second half partake mor rapping than hissing character and are due to vibr of the arterial wall which increases as the press released. The part of the curve where there is sound is where the blood stream sounds are away and the wall sounds are just beginning, an here that the silent gap occurs when both s producing factors are weak.

What has induced me to pin my faith to B in my little work on the subject, where I explai matter more fully, is that he gives various wa testing the correctness of his theory, which I found convincing.—I am, Sir, yours faithfully,

Manchester, Nov. 11th, 1927. FRANCIS HEATHERL

ORGANIC HYPNOTICS.

To the Editor of THE LANCET.

SIR,—We cannot hold you responsible fo opinions expressed by the President of the M Legal Society in his Presidential address on Oct. but, as you publish the address in extenso und heading of Recent Advances in Toxicology Forensic Medicine in your issue of Nov (pp.970–971) we would point out that we, the inve manufacturers, and distributors of the Allonal of Allyl-isopropyl-barbiturate of phenyl-dim dimethylamino-pyrazolon, commonly called A tablets, cannot but regard the inclusion o preparation in the paragraph headed New Dr casting a slur upon, if not actually libellin

duct, ourselves, and also your journal, since you ept and display advertisements in which, according he author of the paragraph named, we make false tements and claims, which "should not be accepted their face value."

or our preparation we would say that: It is the duct of years of patient research by chemists, rmacologists, and toxicologists of hitherto un- bted bona fides and repute; it is manufactured sold as a Roche product, which is accepted ughout the world as a synonym for pharmaceutical parations of the highest class; on entry into this ntry it has to bear its full share of the key industries y; it is advertised and offered only to the medical ession with full disclosure as to its composition and on, and in advertisements and literature regarding o claim nor statement is made which cannot be stantiated and corroborated by the experiences and ions of the most eminent medical men in our own most other countries. Allonal tablets have, during four years they have been on the British market, ed hundreds of enthusiastic users in the medical ession. A member of a partnership of three ors who, in three and three-quarter years, have ght and used 29,000 Allonal tablets in a great strial area of this country, said only yesterday his experience led him to consider the statements ie author of the article under review worse than ir, and that he himself would not willingly be out Allonal, which had enabled him to almost up the use of morphine.

e are therefore quite content to allow Allonal to on its own merits and we make no comparisons een our own preparation and those named in William Willcox's sweeping generalisations and emnations, which are all the more to be deplored they were uttered by one to whom so many for facts and guidance.

We are, Sir, yours faithfully,

E HOFFMANN-LA ROCHE CHEMICAL WORKS, LTD.

Bowes-road, London, N., Nov. 5th, 1927.

To the Editor of THE LANCET.

,—In THE LANCET of Nov. 5th (p. 971), under eading of New Drugs, there is a reference to in remarks made by Sir William Willcox at a t meeting of the Medico-Legal Society. As is a specific reference to Dial, a barbituric acid ative which we handle, we feel that it is incumbent us to submit for your consideration certain ulars relating to this drug.

William Willcox is reported to have stated that g a period of 20 years there were 257 cases of poisoning from the barbituric acid group of . We feel justified in requesting that he will further how many of these fatalities can be ly attributed to therapeutic doses of Dial? In g this request we should like to point out that g a considerable part of the period under review was not even on the market. Moreover, in cally every case where Dial has been mentioned nexion with an overdose of drugs, it has been on investigation that there has been a history er drugs being taken at the same time, resulting, ubt, in a synergistic action. On the other hand, are numerous cases on record in the medical ls where exceptionally large doses of Dial have aken by accident or intent without the produc- f fatal results. We have in our possession the of a case where 100 tablets (150 gr.) of Dial aken and the patient recovered.

le we are in entire agreement with the statement rugs possessing a hypnotic action should be rith care and caution and under medical advice, l justified in taking exception to the suggestion tatements as to their harmless nature (at any s regards Dial) should not be accepted at their alue. Any statements which have been made ertisements regarding the efficacy, safety, and m from toxicity of Dial appearing in THE T can, of course, be substantiated by reference to numerous authorities. Moreover, we feel that such advertisements would not have been inserted in your journal if the statements in them could not have been accepted at their face value.

Regarding the suggestion that such drugs are imported into this country with little restriction as regards duty, whereas similar products of British manufacture are not afforded like facilities, we should like to point out that no drug "similar" to Dial is manufactured in this country. Dial has been exempted from key industry duty for the reason that it is imported for manufacturing purposes, the tablets having been made in this country for many years past. Compounds of Dial and other tablets manufactured in Switzerland are, of course, subject to the full key industry duty of 33⅓ per cent.

We remain, Sir, yours faithfully,

THE CLAYTON ANILINE COMPANY, LIMITED.

40, Southwark-street, London, S.E., Nov. 12th, 1927.

*** Sir William Willcox is reported in THE LANCET of Nov. 5th (p. 971, col. 1) as having said: "It could not be too strongly emphasised that new organic drugs of hypnotic action should be used with great care and caution, and statements as to their harmless nature should not be accepted at their face value." These drugs have been placed on a statutory list of dangerous drugs, and Sir William Willcox is justified in contending that if anyone should state them to be harmless the face value of that statement should be critically examined. We are not aware that either of our correspondents has asserted the nature of their preparations to be "harmless" in opposition to the Home Office view.—ED. L.

CHRONIC EPIDEMIC ENCEPHALITIS:

TREATMENT BY INDUCED MALARIA.

To the Editor of THE LANCET.

SIR,—In connexion with two articles in THE LANCET of Oct. 22nd (pp. 860–862) concerning the treatment of chronic epidemic encephalitis by induced malaria, permit me to draw attention to another form of "fever therapy" which we have tried at the German Hospital. The Saxon Serum Works have supplied us with a preparation called "Saprovitan," consisting of a suspension of living non-pathogenic bacteria. This preparation, injected intravenously in increasing doses, produces a rigor with a temperature from 102°–104° F. within a few hours after the injection. The indications for its use are said to be the same as for fever therapy generally. Opinions differ, however, as to its effciency as a substitute for malaria therapy. We have used it[1] amongst other cases, in a number of patients with chronic epidemic encephalitis (Parkinson's syndrome) allowing 8–10 rigors to occur in each case. In none of these cases did we see any beneficial effect on the symptoms; but we wish to emphasise the debilitating action of this "fever therapy," and, in agreement with P. K. McCowan and L. C. Cook, consider it to be a useless and unjustifiable method.

I am, Sir, yours faithfully,

German Hospital, E., Nov. 11th, 1927. O. B. BODE.

SOME CASES OF ERYTHEMA NODOSUM.

To the Editor of THE LANCET.

SIR,—The contributions by Dr. Maurice Mitman and Dr. Ambrose W. Owen in your issues of Oct. 8th and Nov. 5th illustrate the fact that during the past 12 months there has been an epidemic outbreak of erythema nodosum in various parts of England. I have personally seen 16 cases during 1927, this being the highest number in any 12 months since I began keeping a record in 1907. Five or six cases in the year would be an average with me, but occasionally, at intervals of about four years, as this year and las

[1] O. Bode and J. Axhausen: Erfahrungen mit Saprovitan, Deut. Med. Wochenschr., 1927, liii., 1185.

in 1913 and 1917, the number is doubled or trebled. The maximum number of cases is in the month of April. Erythema nodosum has frequently been noticed to follow upon septic trouble, but I have never noticed its occurrence, as Dr. Owen suggests, at a time when tonsillitis, pulmonary infarcts, pyelitis, or nephritis are unusually prevalent. Possibly erythema nodosum is a special form of streptococcal infection, and the various conditions which he mentions are also of streptococcal origin.

In reply to Dr. Owen's question as to whether the eruption is due to thrombosis or embolism of cutaneous vessels, I may say that I have had several erythematous nodules excised and cut in serial sections; the nodules all show a central thrombosed arteriole lying in the subcutaneous tissue.

I am, Sir, yours faithfully,

Clifton, Nov. 9th, 1927. J. O. SYMES.

MISLEADING QUALIFICATIONS.

To the Editor of THE LANCET.

SIR,—I write again simply to correct the statement made by "F.R.C.S. Edinburgh" that in Scotland the Scottish Fellowship is a compulsory passport to surgical appointments in teaching hospitals. The facts are against him. Classifying the qualifications of the surgical staff of the Glasgow Royal and Western Infirmaries and the Aberdeen and Dundee Royal Infirmaries as given in the Medical Directory of 1925, I obtain the following table:—

—	F.R.C.S. Eng.	F.R.C.S. Edin.	F.R.F.P.S.G.	C.M. or Ch.B. only.	Total.
Glasgow—					
Royal	2	1	9	1	13
Western ..	1	1	3	7	12
Aberdeen ..	2	2	Nil.	5	9
Dundee	2	3	Nil.	5	10
Totals	7	7	12	18	44

It may interest your readers to have the opinion of the General Medical Council on the general question, and with the kind permission of the Registrar I am able to publish his reply to an inquiry of mine.

I am, Sir, yours faithfully,

Nov. 14th, 1927. ETHICS.

*** The letter, which is signed Registrar, G.M.C., Oct. 27th, 1927, runs as follows:—

"In reply to your letter of the 23rd inst., I am directed to say that there appears to be a convention in England that the letters 'F.R.C.S.' represent the Fellowship of the Royal College of Surgeons of England. The letters 'E.' or 'Ed.' and 'I.' are generally added when similar qualifications obtained in Edinburgh and Ireland are used in England. In Scotland, however, and in Ireland, 'F.R.C.S.' alone would probably be taken to refer to the Royal Colleges in Edinburgh, or in Dublin, respectively; while 'F.R.C.S. Eng.' would be used with reference to the Royal College in London. There is certainly no universally accepted rule upon the subject; and there is nothing in Schedule A of the Medical Act, 1859, which would justify the Council in making a formal pronouncement such as you suggest."

RE OVARIAN GRAFTING IN WOMEN.

To the Editor of THE LANCET.

SIR,—I regret that recently an article purporting to be a personal interview with me and containing a highly sensational account of a private lecture given by me to a medical society has appeared in the London press. The facts of the case are these. The wife of one of our members is also a press reporter to several daily papers. She was not known to me by sight, but attended the lecture and sent a report to the lay press. The following morning before I was out of bed or had seen a newspaper I was rung up on the telephone by someone in London whom I took to be the publisher of a certain medical journal asking for an explanation of some points in my lecture. I had just sent him the corrected proofs I answ quite frankly. Later I discovered my error, several reporters called on me. My explanation them only resulted in more "copy," and I refused to see any more. I have also written to London and Counties Medical Protection Society to the various parties concerned.

I am, Sir, yours faithfully,

Manchester, Nov. 14th, 1927. A. C. MAGIA.

HIRSCHSPRUNG'S DISEASE IN ADULT

To the Editor of THE LANCET.

SIR,—I agree with Dr. Hurst that this conditi by no means so rare in adults over 30, as state Dr. Cookson in your issue of Oct. 29th. The follo table, which is taken from my book on "Diseas the Rectum and Colon," shows the ages in collected cases:—

Age.	Cases.	Age.	
Under 5	24	40–50	..
5–10	16	50–60	..
10–20	14	60–70	..
20–30	11	Over 70 ..	..
30–40	7	Not stated ..	..

I am, Sir, yours faithfully,

J. P. LOCKHART-MUMME

Hyde Park-place, W., Nov. 11th, 1927.

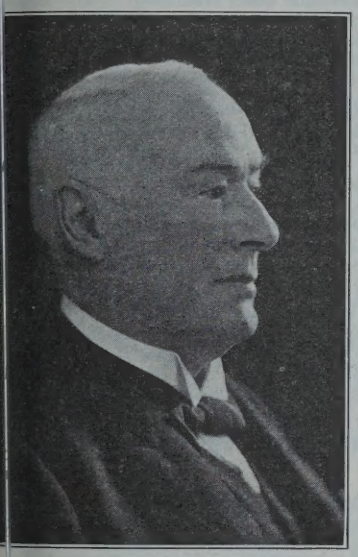
Obituary.

SIR PETER REILLY O'CONNELL, M.D., M.CH. R.U.I., D.L.

Sir Peter O'Connell, who died at Marseilles on pt. 24th whilst on holiday, was for many years a tinguished figure in the public life of Belfast. rn in Co. Cavan, he went to the city as a young n in 1883, after studying medicine in Dublin and ndon and on the continent. His reputation even en had preceded him, and his abilities soon came the fore when with a few colleagues he formed the cleus of the present Mater Infirmorum Hospital. re he laboured hard, both late and early, and when 1900 the present building was opened with 200 beds, was appointed senior surgeon. In this capacity he l ample scope for his talents, and soon his opera- e skill and clinical judgment brought patients from all over Ulster. Though a busy man, he spent much time in reading and writing on other subjects besides those of his profession, and he was interested in societies for the improvement of the people. He became prominent as a speaker, and at the request of many of the citizens entered public life as an Alderman of the City of Belfast. In the corporation he was soon an outstanding figure, taking a keen interest in public



SIR PETER O'CONNELL.

th, technical and educational committees. His of oratory and sound argument gained him gh place in the esteem of his fellow-citizens, in 1909 he was elected High Sheriff of the by men who differed from him both in religion politics, but recognised his great ability. As a rd for his services he was created a Knight elor in 1908; he also became Deputy Lieutenant he City. He was appointed on a commission to ire into University education in Ireland, which ted in the establishment of the National and n's University, and of the latter University he appointed a senator, acting also as lecturer and iner in surgery. Although devoting much of nergies to public affairs he always found time to d the medical meetings and to contribute to their sactions, and for the year 1910–11 he served as dent of the Ulster Medical Society. Sir Peter nnell retired about six years ago, and went to in the suburbs of Dublin. During his frequent s to Belfast he was always welcomed by his former iates, and in the places where he had once been inent.

colleague, to whom we are indebted for these aphical details, writes: "In the Mater, where ad laboured for nearly 40 years, we shall miss enial presence, his candid advice, his sallies of his professional skill; but his name and fame it large in its history, and future generations will the deep debt they owe to 'Sir Peter.'"

dy O'Connell, who survives him, is the daughter e late Mr. Edward Hughes, J.P.

JOHN SINGLETON DARLING, M.D., M.CH. DUB.

DEEP regret is felt in Ulster at the death of Dr. J. Singleton Darling which occurred on Nov. 8th, at the age of 71, after a long illness. Dr. Darling received his medical education at Trinity College, Dublin, where he graduated in the year 1879. He afterwards studied in Vienna, having gained the medical travelling prize at Trinity College. He settled in Lurgan and soon acquired a large practice. He was appointed medical officer of the Lurgan Workhouse Infirmary and effected many improvements in that institution, which is now one of the best appointed and successful hospitals in Northern Ireland. Dr. Darling filled many important positions. He was at one time president of the Ulster Medical Society and of the Ulster branch of the British Medical Association. He took an active interest in the affairs of the Association, and at various times acted as a member of its Council. He was a regular attender at the quarterly meetings of the Ulster branch, and made many valuable contributions to its proceedings. Dr. Darling enjoyed in a high degree the respect and affection of his medical brethren. A man of considerable professional attainments, scrupulous honour, genial and fraternal character, he occupied a distinguished place in the ranks of the profession. He leaves a widow and a large family.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on Nov. 12th the following degrees were conferred:—

M.B. & B.Chir.—J. L. Warner.
M.B.—W. H. Craib.

UNIVERSITY OF GLASGOW.—On Nov. 12th the degrees of M.B. and Ch.B. were conferred on Eric Dow, and the degree of B.Sc. on Martha Cleland, M.B.

UNIVERSITY OF MANCHESTER.—Dr. Reginald Ellis has been appointed assistant lecturer in applied physiology, and Dr. Marguerite F. Johnstone has been elected to the John Henry Agnew Fellowship in the Diseases of Children.

UNIVERSITY OF BIRMINGHAM.—On Nov. 11th the following prize medals were distributed:—

Arthur Foxwell Memorial Medal (awarded for Clinical Medicine in the Final M.B. Examination): Marjorie V. Martin.—Sampson Gamgee Memorial Medal in Surgery (awarded at Final M.B. Examination): Kenneth P. Fooks.—Senior Medical Prize: Frances M. Stockdale.—Senior Surgical Prize: Victor Goldman.—Midwifery Prize: Robert Anderson. Junior Medical Prize: John W. Notley.—Junior Surgical Prize: Beatrice M. Willmott.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council, held on Nov. 10th, Sir Berkeley Moynihan, the President, in the chair, the following resolution was adopted and entered on the Minutes:—

"On the occasion of the retirement of Mr. Frederic G. Hallett from the offices of Secretary to the Conjoint Examining Board and Director of Examinations in the Royal College of Surgeons, the Council desire to place on record their high appreciation of his services and the very warm regard which they entertain for him personally. Mr. Hallett's powers of organisation, his long experience in all matters relating to examinations, and his exceptional knowledge of regulations for medical education in this and other countries have been of great advantage to the College, and have given his services a special value and caused them to be held in the highest regard. The Council are fully conscious of the ability and zeal with which Mr. Hallett has carried out his duties during the long period of 50 years, and they trust that health and happiness may enable him to enjoy in his retirement the rest which he has earned so well. His unfailing courtesy and readiness to help will not be forgotten by those who have had the pleasure of being associated with him in the control and management of the affairs of the College, and the Council assure him that he carries with him their best wishes for his welfare in years to come."

With reference to the resolution carried at the annual meeting of Fellows and Members in November, 1926, the following resolution was unanimously adopted:—

"That, in view of the result of the recent postal vote of the Fellows, the Council is not prepared to take steps at the present time for altering the constitution of the College so as to give Members of the College direct representation on the Council."

THE Minister of Health and the Minister of Agriculture and Fisheries have appointed a Joint Advisory Committee, with Sir Horace Monro as chairman, to consider, and from time to time to report on, the pollution of rivers and streams, and on any measures which they think desirable for its diminution. The only medical member of the committee is Dr. H. Maclean Wilson. Communications should be addressed to Mr. G. C. North at the Ministry of Health.

A CONGRESS ON LIGHT AND HEAT IN MEDICINE.—The first International Exhibition and Conference on Light and Heat in Medicine and Surgery will be held at the Central Hall, Westminster, from Dec. 13th to 16th inclusive. The exhibition will be opened at 2.30 P.M. on Dec. 13th by Sir Alfred Mond. The arrangements are in the hands of the *British Journal of Actinotherapy* (17, Featherstone Buildings, London, W.C. 1), and medical men or others professionally interested, who wish to contribute papers or receive invitations, are asked to communicate their names.

BRITISH SERBIAN UNITS.—The annual re-union dinner of the British Serbian Units Branch of the British Legion, and of all friends of Serbia, will be held on Saturday, Dec. 3rd, at 7.15, at the Victoria Mansions Restaurant, 24, Victoria-street, Westminster. The President, the Rev. R. G. D. Laffan, will take the chair. Tickets may be had from Miss Marx, 24, Melcombe-court, Dorset-square, London, N.W. 1.

BRADFORD INFIRMARY.—Work has now begun upon the great new infirmary which is to contain 435 beds and to cost half a million. The block upon which the builders are engaged is to be a self-contained unit reserved for paying patients.

HOSPITAL ACCOMMODATION FOR JEWS.—Last week the Marquis of Reading opened new wards in the Jewish Maternity Home in Underwood-street, Whitechapel. The Hebrew community of Liverpool is laying plans for the provision of a Jewish ward in one of the city hospitals. It is complained that at present Jewish hospital patients are unable to obtain orthodox food, and that the unaccustomed diet "often has an adverse effect upon them."

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the annual meeting of the Faculty on Nov. 7th the following office-bearers were elected for the ensuing year: President, Dr. G. H. Edington; visitor, Dr. John F. Fergus; hon. treasurer, Mr. J. H. MacDonald; hon. librarian, Dr. E. H. L. Oliphant; representative on the General Medical Council, Dr. James A. Adams. Council: The President; visitor, treasurer, librarian, and representative on the General Medical Council, ex officio; Dr. John Henderson, Dr. H. L. G. Leask, Mr. R. Barclay Ness, Dr. T. K. Monro, Dr. W. G. Dun, Mr. J. Forbes Webster, Dr. J. M. Munro Kerr, Mr. Thomas Kay, Mr. John Patrick, and Mr. R. M. Buchanan. Dr. G. H. Edington, the new President, was invested with a badge of office, presented by his predecessor, Dr. R. M. Buchanan. The following candidate was admitted (after examination) as a Fellow of Faculty, Sheik Abdool Majid Sepher.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Mr. Arthur Edmunds will deliver a lecture on Practical Surgical Details on Monday, Nov. 21st, at 5 P.M., at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W. On Wednesday, Nov. 23rd, at 2.30 P.M., a special demonstration will be given at the Prince of Wales's General Hospital, Tottenham, N. On Thursday, Nov. 24th, at 2 P.M., Mr. Whitchurch Howell will give a surgical demonstration at the Queen's Hospital for Children, and on the same day, at 1 P.M., Mr. Whiting will demonstrate at the Royal London Ophthalmic Hospital, City-road, E.C. Members of the medical profession are invited to attend the lecture and demonstrations without fee. From Nov. 21st to Dec. 17th, at 5 P.M., at the West End Hospital for Nervous Diseases, a series of lecture-demonstrations will be given, illustrated by cases. A post-graduate course on Diseases of the Rectum will be held at the St. Mark's Hospital from Nov. 28th to Dec. 3rd. From Dec. 5th to 17th, at the Infants Hospital, an afternoon course on infants' diseases will be given under the direction of Dr. Eric Pritchard, and an afternoon course at the Hospital for Diseases of the Skin, Blackfriars, will be held between the same dates. During January courses will be given in medicine, surgery, and the specialties at the Prince of Wales's General Hospital and associated hospitals, in cardiology at the National Hospital for Diseases of the Heart, in diseases of children at the Children's Clinic, and in psychological medicine at the Bethlem Royal Hospital. Information, syllabuses, and tickets may be had from the Secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

UNIVERSITY OF SHEFFIELD.—Dr. Percival H has been appointed honorary lecturer in ophthalmolo and Mr. J. L. Grout, F.R.C.S. Edin., honorary lecturer radiology.

JERVIS-STREET HOSPITAL, DUBLIN.—A new wi with a laboratory and an X ray department, is being ad to this institution at a cost of £50,000. The new buildi are nearly completed.

BIRMINGHAM STUDENTS' CARNIVAL.—This ye carnival for the benefit of the Birmingham hospitals produced approximately £5500, the largest amount obtained.

CREMATIONS IN MANCHESTER.—The Manches Crematorium, Limited, state that the total number cremations since 1892 is 4974, the numbers for each of last five years being as follow: 1923, 222; 1924, 2 1925, 265; 1926, 297; and 1927, 352.

NEW CASUALTY DEPARTMENT AT WALSALL.—T number of casualties received at this hospital, made fam by Sister Dora, has so greatly increased that a new dep ment is to be provided for their treatment. The secret of the hospital recently pointed out to 20 insurance c panies the extent of the benefits they derive from this in tution, but received only one acknowledgment, wit donation of £1.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—T new out-patient department of this hospital at 234, G Portland-street, London, W., will be opened by the L Mayor on Tuesday, Nov. 22nd, at 12.15 P.M. The build which costs £58,500, contains departments for mass electrical treatment, exercises, light treatment, X ray w and surgical instrument and bootmaking workshops, will be open for inspection between 11 and 12 o'clock be the opening ceremony.

ROYAL EAST SUSSEX HOSPITAL.—A new childr ward is to be built on the foundations of the nurses' h which were laid before the war. The extension will inv the building of a corridor, 100 feet in length, from the n building, and this corridor, which will be fitted with sli windows of vitaglass, is to accommodate ten beds. new ward is being given by Mrs. Whitefoord in men of her son, and will hold 20 patients. When the enla ment is complete the hospital will have 154 beds ins of the present 114.

FREE TREATMENT FOR HOSPITAL SUBSCRIBERS The Manchester and Salford Hospital Saturday and Convalescent Homes Fund has approved of a scheme for secu free treatment in the hospitals of Manchester and Sal to all subscribers to the fund who consent to increase t subscriptions by 1*d.* to 2*d.* a week. Although the f contributes £12,000 a year to the local medical chari nothing is received in return, whereas in Birmingham Leeds, where similar schemes are in operation, the co butors obtain free treatment. It is believed that by adoption of the proposed plan an additional £20,000 a would be received, 85 per cent. of which would go to hospitals and the remainder to the convalescent homes.

PRESENTATIONS TO MEDICAL MEN.—A prese tion of his portrait to Prof. R. B. Wild was made Nov. 10th by Prof. G. R. Murray on behalf of Prof. W past and present colleagues in the Faculty of Medicin the University of Manchester and in recognition of valuable services to medicine and education. Prof. expressed a desire to offer the portrait to the Univer on whose behalf it was gratefully accepted by the Chancellor. Prof. Wild retired last September from Leech Chair of Materia Medica and Therapeutics, whic had held for a quarter of a century.—Dr. C. F. W who for several years has been assistant port me officer at Liverpool, and is about to leave the city to up an appointment as a medical officer at the Minis of Health, was on Oct. 27th presented by the staff of department with a handsome chiming clock and a Dr. A. A. Mussen, who presided, paid a warm tribute t efficiency which Dr. White had brought to bear on work, and said they all regretted his departure.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, NOV. 10TH.

Tuberculous Ex-Service Men and Treatment Allowances.

Mr. ROBINSON asked the Minister of Pensions whether it is now the practice to refuse treatment allowances to men suffering from tuberculosis and unable to work who are under treatment by their panel doctor, and what was the estimated saving that might result from the withdrawal of treatment allowances in these cases.

Mr. DENNISON asked the Minister of Pensions if his attention had been drawn to the concern among disabled men suffering from pulmonary tuberculosis at the reduction of pensions and the withdrawal of treatment allowances, and whether an instruction had been issued to the medical officers that men in receipt of 100 per cent. pension in respect of tuberculosis were to be taken off treatment allowances and put on their flat-rate pension.—Major TRYON replied: No general instruction has been issued that men suffering from tuberculosis in consequence of their war service are to have their treatment allowances withdrawn. I understand, I find that some 1600 cases were admitted to such treatment allowances in consequence of treatment during the quarter ended in September last. The provisions of the Royal Warrant make it a condition of the grant of these allowances that the patient is rendered unable to provide for himself by the consequence of the treatment which is ordered for him. It is therefore the necessary duty of my department to review from time to time all cases in which allowances are being paid in order to see that the Warrant conditions are fulfilled. The terms of the Warrant apply to tuberculosis as well as to all other disabilities, but in the case of tuberculosis the circumstances of each individual patient are considered in consultation with the responsible medical officer of the local authority. So far from there being any attempt to reduce pensions in these cases, special arrangements have been made to ensure that any man whose treatment allowances are discontinued under the terms of the Warrant is examined in regard to his rate of assessment of pension purposes and any increase appropriate to his case is granted. These arrangements have in fact resulted in a substantial increase in the average rate of pension for tuberculosis disability.

Pensioners and Poor-law Medical Attention.

Mr. GROVES asked the Minister of Pensions: (1) Whether he had given personal consideration to and sanction of the present practice of the Pensions Issue Office in deducting from a pensioner's allowance an amount said to be claimed by the West Ham Board of Guardians whenever a pensioner was sent into the Whipps Cross Hospital, which was within the West Ham Poor-law Union; and (2) whether his department made any inquiries as to the reasonableness of the demand upon a pensioner's allowance, when such pensioner had entered an institution under a Poor-law authority, for any medical advice or attention.—Major TRYON replied: Under the provisions of the Royal Pension Warrants a claim made by a board of guardians in respect of a pensioner admitted to a Poor-law institution for maintenance or medical treatment not connected with his war service is met by repayment to the guardians out of the man's pension. The amount so collected may not exceed the ordinary rate for the maintenance of inmates or the daily rate of pension in payment, whichever is the less. The provision referred to is not a new one, but has been in operation for many years and applies to all Poor-law institutions.

Dental Clinics.

Colonel APPLIN asked the Minister of Health whether attention has been drawn to the establishment of dental clinics by various approved societies; and what steps he proposed to take in this matter.—Mr. CHAMBERLAIN replied: Approved societies have no power under the National Health Insurance Act to establish dental clinics, but a few clinics have been established by bodies indirectly associated with approved societies. I have referred the general question of the provision of dental treatment in clinics to a Medical Committee representative of approved societies and dentists, and I am hoping very shortly to receive a report on the subject.

Poor-law Relief.

Mr. LANSBURY asked the Minister of Health the number of able-bodied persons, together with their dependents, in receipt of Poor-law relief, institutional and outdoor, during each of the 12 months ending Oct. 31st, 1927.—Mr. CHAMBERLAIN replied: The following is the information asked for:—Figures based on a classification distinguishing "able-bodied" persons are not now obtained. The available information is set out below.

1. Number of persons (not being persons suffering from sickness, accident, or bodily or mental infirmity and not being casuals) in receipt of institutional Poor-law relief in England and Wales.

	Men.	Women.	Children.	Total.
Jan. 1st, 1926	37,493	18,366	42,699	98,558
„ 1927	40,343	18,702	42,206	101,251

Corresponding particulars for each month are not available.

2. Average number, for each of the undermentioned months, of the persons in receipt of outdoor Poor-law relief in money or kind in England and Wales who were classified, in returns made by the guardians to the Minister of Health, as "persons ordinarily engaged in some regular occupation and dependent wives and children of those persons."

Month.	Men.	Women.	Children.	Total.
November, 1926 ..	389,513	368,188	732,166	1,489,867
December, 1926 ..	284,292	259,950	523,561	1,067,803

September, „ ..	127,825	110,404	227,756	465,985

October, 1927: Information not yet available.

Average Cost for Medicine for Insured Persons.

Mr. HARDIE asked the Minister of Health the average cost per person per form for medicine for insured persons in Glasgow, London, and any other large cities.—Mr. CHAMBERLAIN replied: I am not clear as to the precise information desired by the hon. Member, but I may say that the average cost per prescription during August last, the latest month for which figures are available, was as follows: London, 8·1*d.*; Birmingham, 7·8*d.*; Manchester, 8·9*d.*; Liverpool, 8·5*d.* As regards Glasgow I suggest that the hon. Member should address a question to the Secretary of State for Scotland. (This figure was given later as 13·41*d.*).

Position of Voluntary Hospitals.

Mr. THOMAS WILLIAMS asked the Minister of Health whether he was able to make any statement indicating what steps he was likely to take with regard to the Onslow Report on Voluntary Hospitals.—Mr. CHAMBERLAIN replied: I have already indicated that, in the present financial position, I cannot recommend any grant from public funds towards the cost of extensions of voluntary hospitals, but I am glad to be able to say that, since the report of the Commission was received, the position has improved and a considerable number of new beds have been provided or are in course of provision.

Birth Control and Decline in the Birth-rate.

Sir NICHOLAS GRATTAN DOYLE asked the Minister of Health whether his attention had been called to the decrease in the national birth-rate, and if he had considered the desirability of curtailing the activities of certain birth-control societies and other agencies.—Mr. CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. As regards the second part I have no control over the activities of these agencies.

Foreign Condensed Skimmed Milk.

Sir ROBERT SANDERS asked the Minister of Health whether inquiries had been made on behalf of his department as to the conditions of manufacture of condensed skimmed milk imported from Holland and Denmark; by whom the inquiries were made; and whether he would lay the report on the table of the House.—Mr. CHAMBERLAIN replied: My information is that the sale of condensed skimmed milk is not forbidden in Holland. Inquiries as to the conditions of production in Holland and Denmark have recently been made by Dr. J. M. Hamill, one of my medical officers, Mr. T. A. Hole, a milk inspector in my department, and Mr. James Mackintosh, Professor of Dairy Husbandry at the University of Reading. I am considering in what form I can best submit for the information of hon. Members the results of their investigation, including the scope of the regulations in force.

Luneside Sanatorium, Lancaster.

Mr. BROMLEY asked the Minister of Health how many of the inmates of the Luneside Sanatorium, Lancaster, lost their lives as a result of the recent flooding of that institution; if he had made any inquiries into the lack of precautions which allowed such an occurrence; and if any measures would be taken to make such an event impossible in future.—Mr. CHAMBERLAIN replied: I regret to say that three patients lost their lives as a result of the recent flooding of this institution. According to the press reports of the inquest the flooding was of an unprecedented character, and there was no suggestion that all reasonable precautions had not been taken. I am in communication with the Lancashire County Council on the question of the future use of this institution for tuberculous patients.

Dismissal of a Medical Officer.

Mr. WILLIAM THORNE asked the Minister of Health if it was his intention to hold an inquiry into the circumstances of the dismissal of the general medical officer of the women's section of the Park Prewitt mental institution, Basingstoke, which resulted in the wholesale resignation of the staff.—Mr. CHAMBERLAIN replied: The answer is in the negative. The dismissal of the medical officer in question is primarily a matter for the local authority by whom he was employed. As regards the alleged wholesale resignation of the female staff I am informed that out of a total staff of 138 only 32 resigned, and that on the 1st of this month the female nursing staff was only six below the normal strength.

Medical Tests for Driving Licences.

Sir HARRY BRITTAIN asked the Minister of Transport whether and when it was intended to introduce medical and other tests before granting driving licences.—Colonel W. ASHLEY replied: My proposals with regard to the conditions with which applicants for driving licences should comply are contained in Clauses 14 and 15 of the Draft Road Traffic Bill which I caused to be published and circulated some time ago.

Sale of Tuberculous Fish.

Sir WALTER DE FRECE asked the President of the Board of Trade if his attention had been drawn to the sale of tuberculous fish, and if he would have investigations made with a view to prohibiting such sales.—Mr. CHAMBERLAIN replied: No, Sir. I am advised that there is no danger of the communication of tuberculosis to man from the consumption of fish.

MONDAY, NOV. 14TH.

Proposed Medical Mission to China.

Mr. THURTLE asked the Under Secretary of State for India the reason for the refusal of the Government of India to allow the proposed medical mission of a non-political character to be sent to China.—Earl WINTERTON replied: The reasons for which facilities for the proposed medical mission to China were refused were, firstly, that the grant of facilities for a party of British subjects to serve even as non-combatants with one or other of the contesting factions in the civil war in China would have been likely to be construed as a departure by His Majesty's Government from their attitude of strict impartiality; and, secondly, that at a time when His Majesty's Government had caused all British subjects to be advised to withdraw from the interior of China, in order to avoid embarrassing incidents, it was impossible to allow a considerable party of British subjects to proceed to those parts of China where such incidents would have been most likely to occur.

India Office and "Mother India."

Mr. RENNIE SMITH asked the Under Secretary of State for India whether, in view of the feeling aroused in India by the publication in this country of Miss Katherine Mayo's book, "Mother India," he could say whether Miss Mayo was assisted in the production of this book by the India Office or the Government of India.—Earl WINTERTON replied: Miss MAYO received no assistance in the production of her book, either from the India Office or from the Government of India, beyond the supply of official information on matters of fact which is afforded to any member of the public who asks for it.

Sale of Opium in Rangoon.

Mr. KELLY asked the Under Secretary of State for India whether he was aware that at the monthly meeting of the Rangoon corporation in September resolutions were passed to the effect that in their opinion the reopening of opium registers for Burma consumers was not desirable and not in the public interest, and urging His Majesty's Government to veto the proposal to legalise the sale of opium in Rangoon; and what steps the Government proposed to take in the matter.—Earl WINTERTON replied: I have seen a press report of the resolutions referred to. The Governmen Burma had already decided not to reopen the opium regis for Burman consumers without a clear mandate from th affected. The other resolution referred not to opium to ganga. As regards the last part of the question I wo remind the hon. Member that excise is a transferred subj

Death and Invaliding Rate in Gold Coast Mines.

Mr. HAYES asked the Under Secretary of State for Colonies the death and invaliding rate in the Gold C gold mines.—Mr. ORMSBY GORE (Under Secretary for Colonies) replied: The total number of workers emplo in the gold mines in the Gold Coast during the year A 1926, to March, 1927, was 8240, and the deaths during period were 98, of which 14 were due to accidents and 8 diseases. The death-rate was therefore approximately per 1000. No figures are available as to the invalid rate.

Government and the Licensing Laws.

Sir FRANK MEYER asked the Prime Minister wheth was his intention to set up a commission or committe inquire into the working of the present Licensing Iw for the regulation of the consumption of alcoholic liq and whether he was aware of the dissatisfaction with present laws.—Mr. BALDWIN replied: I am aware there are many points in the existing licensing laws w may be said to dissatisfy different sets of opinions, and whole question is under the consideration of the Gov ment who are not prepared to make a statement at pre

Consumption of Milk in London.

Mr. HURD asked the Minister of Agriculture if he c give an estimate of the increased consumption of li milk in London in gallons and percentages in the past years, allowance being made for any increase in the po tion; and what educational and other means were taken to increase this consumption in the interests of p health and agriculture.—Mr. GUINNESS replied: In half-yearly report of the National Milk Publicity Co the following figures are given, compiled from statis rendered by the four principal railway companies for brought into London by rail:—

Year ending June 30th.	No. of gallons, in millions.	Percen increase since 2
1923	72	—
1924	77	7
1925	99	37
1926	107	48
1927	117	62

It is further estimated that at least 5,000,000 gallon annum are brought into London by road. The av increase in the population of Greater London over period has been less than 50,000 per annum, that is than 1 per cent. The question of educational and steps to increase the consumption of milk is dealt wi some length in a report on the Fluid Milk Market, wh to be issued in a few days as No. 16 of the Economic S Briefly, it may be said that up to the present such a has been limited to the steps taken by the National Pub Council which is maintained by voluntary contribu from farmers, manufacturers, and distributors.

Small-pox Statistics.

Dr. VERNON DAVIES asked the Minister of Health fo small-pox statistics for England and Wales for the m of August, September, and October last, and the number of cases since Jan. 1st, 1927.—Sir KINGSLEY replied: The numbers of cases of small-pox notified i months of August, September, and October were 564 and 795 respectively, and the total number of notifica during the period from Jan. 2nd last to Nov. 5th incl was 12,729. These figures are subject to revision.

Whipps Cross Hospital: Cost of Patients and Char Patients.

Mr. GROVES asked the Minister of Health the av cost of maintenance of the patients at the Whipps Hospital of the West Ham Union.—Sir KINGSLEY replied: In the returns made to my right hon. fr department the expenditure in respect of the Whipps Hospital is not shown separately from that in resp the Forest House and Forest House Cottages of the Ham Union. The average weekly expenditure per i of this group of institutions for the year ended March 1927, was 45*s.* 10½*d.*

Mr. GROVES also asked the Minister of Health wh he was aware that, owing to the pressure upon the ord voluntary hospitals of the East End of London and

riction of accommodation, there had been an increase the number of patients sent by medical men to the ipps Cross Hospital; that these persons generally were king people who would not like normally to seek parish) and that if they had been received into the ordinary pital they would have been asked what they could rd to subscribe; that the West Ham guardians made a ailed and heavy charge upon the whole of the members he family of the inmate; and whether he would con- r making such changes in medical treatment charges in 1 institutions that sick persons were only asked to sub- be similar sums to those charged by the local voluntary pitals.—Sir KINGSLEY WOOD replied: It is the duty of oard of guardians to take all reasonable steps for the very of the cost of any relief which they may afford ick or other persons, and they could not lawfully adopt stem of small fixed charges or limit their purview in ding upon such cases in the manner which the question ests is adopted by the authorities of voluntary hospitals.

Approved Societies and Convicted Persons.

r. THOMAS WILLIAMS asked the Minister of Health if vas aware that certain approved societies employed a to dismember an insured person on that person being icted and punished for an offence; and what steps he ided to take to discourage the application of any such by which an approved society sought to supplement punishment of a bench of magistrates.—Sir KINGSLEY ID replied: The rules of most approved societies provide the committee of management may expel a member has been imprisoned for any crime. Before a member be expelled under this rule, however, the committee is ired to give him a full opportunity of submitting his nce, and if a decision to expel him is arrived at he has ht of appeal, first to an independent arbitration tribunal, finally to the Minister. My right hon. friend thinks, efore, that insured persons are already sufficiently ected against a harsh or unreasonable application of rule.

Drowning Fatality in a London Hospital.

r. DAY asked the Minister of Health whether his atten- had been drawn to the remarks of the coroner at an est held at Hammersmith regarding the death of a an who was found dead through drowning in a bath f water at a hospital, and who had taken a bath against uctions; and whether any precautions had been taken is department to instruct the hospital authorities under ontrol to carry out the coroner's suggestions to have aps in bathrooms controlled to prevent such further bilities.—Mr. CHAMBERLAIN replied: I am aware of acts of this case. The importance of having keys to t water taps in the bathrooms of Poor-law institutions r many years been emphasised by the central authority, I am informed that such keys have now been fitted to e bath taps at this institution.

TUESDAY, NOV. 15TH.

Consumption of Milk in Great Britain.

R. ROBERT MORRISON asked the President of the Board ade the consumption of milk per head of the population reat Britain and Northern Ireland in the years 1924, and 1926, respectively.—Mr. GUINNESS replied: the results are available of the last census of agricul- production in Scotland and Northern Ireland, it is possible to make very approximate estimates of mption of milk in the United Kingdom. It has been lated, however, that the per head consumption of liquid in the United Kingdom during each of the years ied in the question was about 20 gallons. During the periods the amount of tinned milk consumed was alent to rather over two gallons of liquid milk per head.

Village Settlements for Tuberculosis Treatment.

MR. HORE-BELISHA asked the Minister of Health whether tention had been called to the resolution passed by Plymouth insurance committee, requesting that the rnment be urged to make provision enabling and ring local authorities dealing with the treatment of culosis, or groups of these, to formulate schemes for e settlements where suitable ex-sanatorium patients their families might be housed and appropriate nerative employment provided under medical super- on the lines adopted at the Cambridgeshire tuber- s colony at Papworth Hall; and what was the policy department with regard to this matter.—Sir KINGSLEY replied: The answer to the first part of the question the affirmative. As regards the second part of the on, there are three village settlements in existence fourth is under consideration. My right hon. friend's is that fuller experience of the results in these cases be awaited before attempting such widespread and developments as are suggested in the question.

Medical Adviser to Mines Department.

Mr. LUNN asked the Secretary for Mines if he could now give the name of the new medical adviser to the Mines Department and his qualifications to enable him to deal with the various diseases peculiar to the mining industry.—Colonel LANE FOX replied: Dr. S. W. Fisher has been appointed Medical Inspector of Mines and Quarries. Since his demobilisation in 1919 Dr. Fisher has practised in a colliery district in South Wales, where he has obtained general experience of mining conditions and of the treatment of cases of mining accidents and disease. He has taken special interest in silicosis and nystagmus, in which he has carried out research work, and in beat-hand, beat-knee, and beat-elbow.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Nov. 22nd.—5 P.M., MEDICINE. Clinical meeting in the Library of St. Bartholomew's Hospital Medical College.

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Paper: Dr. Edgar Obermer: The Endocrinology of Tuberculosis. 5.30 P.M., BALNEOLOGY. Presidential Address: Dr. L. C. E. Calthrop: The Scientific Basis of the Practice of Medical Hydrology. A polychromide film of the solar eclipse, 1927, will be shown after the Presidential Address.

THURSDAY.—8.30 P.M., DISEASE IN CHILDREN, THERAPEUTICS, UROLOGY. Special discussion on the Treatment of Pyuria in Children. Openers: Dr. E. A. Cockayne (Study of Disease in Children), Dr. E. H. Lepper (Therapeutics), and Mr. John Everidge (Urology).

FRIDAY.—5 P.M., DISEASE IN CHILDREN. (Cases at 4.30 P.M.) 8 P.M., EPIDEMIOLOGY. Paper: Dr. E. H. R. Harries: Immunity in the Making.

MEDICO-LEGAL SOCIETY, at 11, Chandos-street, Cavendish-square, W.

THURSDAY, Nov. 24th.—8.30 P.M., Paper: Captain Norman Parkes: A Case of Pathological Drunkenness as a Defence of Insanity at a Murder Trial.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, Nov. 25th.—8.30 P.M., Papers will be read by Dr. P. H. Manson-Bahr and Dr. H. S. Stannus on Yaws. A discussion will follow.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Nov. 21st, to SATURDAY, Nov. 26th.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society, 11, Chandos-street, Cavendish-square, W., on Mon., at 5 P.M., by Mr. A. Edmunds: Practical Surgical Details.—PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N. Wed., 2.30 P.M., Special demonstration by Dr. Browning Alexander.—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E. Thurs., 2 P.M., Special demonstration by Mr. Whitchurch Howell.—ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C., Thurs., 1 P.M., Special clinical demonstration by Mr. Whiting. The above lectures are free.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Post graduate course in Medicine, Surgery, and Gynæcology, second week.—ST. PETER'S HOSPITAL, Henrietta-street, W.C. Special course in Urology.—WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street, W. Lecture-demonstrations illustrated by cases, daily, at 5 P.M., for four weeks. Further information from the Secretary.

CHARING CROSS HOSPITAL.

THURSDAY, Nov. 24th.—3 P.M., Sir Archibald Garrod: Recent Advances in Science in Relation to Medicine and Surgery (Huxley Lecture).

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.

WEDNESDAY, Nov. 23rd.—4 P.M., Dr. C. E. Lakin: Clinical Demonstration of Medical Cases.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.

MONDAY, Nov. 21st.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Donald Armour: Operations. 2 P.M., Dr. Trevor Davies: Gynæcological Out-patients.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 2 P.M., Mr. Addison: Operations. 4.30 P.M., Dr. Scott Pinchin: Cardiac Irregularities (lecture).

WEDNESDAY.—10 A.M., Dr. Owen: Children's Department. 10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations.

THURSDAY.—11 A.M., Resident Assistant Surgeon: Ward Demonstrations. 3 P.M., Sir Henry Simson: Gynæcological Ward Visit. 4.30 P.M., Mr. Tyrrell Gray: Gastric and Duodenal Ulcer (lecture).

FRIDAY.—11 A.M., Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.

Daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M., In- and Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Nov. 21st.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

There will also be a special demonstration of Surgical Cases on Tuesday at 2 P.M., and of Medical Cases on Friday at 2 P.M., by Mr. W. E. Tanner and Dr. L. R. Yealland respectively.

ROYAL NORTHERN HOSPITAL, Holloway, N.: POST-GRADUATE INTENSIVE COURSE.

MONDAY, Nov. 21st.—2.15 P.M., Dr. W. R. Reynell: The Epilepsies. 3.15 P.M., Mr. Kenneth M. Walker: Tuberculosis of the Genito-urinary Tract.

TUESDAY.—2.15 P.M., Mr. T. Twistington Higgins: Demonstration of Surgical Cases. 3.15 P.M., Dr. C. Gouldesbrough: A Demonstration of X Ray Methods in the New Department.

WEDNESDAY.—2.15 P.M., Dr. H. Semon: Ringworm. 3.15 P.M., Dr. J. W. McNee: Recent Work on Acute Specific Fevers.

THURSDAY.—2.15 P.M., Mr. John B. Hunter: Head Injuries. 3.15 P.M., Mr. C. S. Lane-Roberts: Failed Forceps Cases.

FRIDAY.—2.15 P.M., Mr. A. M. Zamora: Acute Ear Infections. 3.15 P.M., Mr. F. D. Saner: Demonstration of Surgical Cases.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Nov. 22nd.—5 P.M., Dr. J. A. Drake: Leprosy.

THURSDAY.—5 P.M., Dr. A. Whitfield: Tuberculosis Cutis.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Nov. 25th.—4 P.M., Mr. A. Brown: Significance of Aural Pain.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Nov. 24th.—4 P.M., Dr. Pearson: Abdominal Enlargement.

ANCOATS HOSPITAL, Mill-street, Manchester: POST-GRADUATE LECTURES.

THURSDAY, Nov. 24th.—4.15 P.M. (tea at 3.45 P.M.), Mr. E. E. Hughes: Diagnosis and Treatment of Common Affections of the Rectum.

ST. PAUL'S HOSPITAL, Endell-street, W.C.: POST-GRADUATE COURSE.

THURSDAY, Nov. 24th.—4.30 P.M., Mr. Frank Kidd: Treatment of Tumours of the Bladder.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Nov. 22nd.—4.15 P.M., Mr. J. Morley: The Mechanism of Abdominal Pain.

FRIDAY.—4.15 P.M., Dr. R. Veitch Clark: Immunisation against Diphtheria and Scarlet Fever.

l London Ophthalmic Hospital, City-road, E.C.—Hon. Dent. S. Also Two Assistants in Refraction Dept. for L.C.C. School-children. At rate of £160.

l Northern Hospital, Holloway, N.—Ophth. S.

Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Anæsthetist. At rate of £25.

bury General Infirmary.—H.S. £150.

ghai Municipal Council, Public Health Dept.—Asst. Radiologist. £1050.

a Leone, School Laboratory, Freetown.—Two Research Assts. Each £600.

rd County Mental Hospital.—Second Asst. M.O. £600.

rdshire Mental Hospital, Cheddleton, Leek.—Jun. Asst. M.O. £350.

ng District Mental Hospital, Larbert.—Sen. Asst. M.O. £400.

sea Hospital.—H.S. to Ophth. and Aural Depts. £150–£200.

rick County Mental Hospital, Hatton.—Asst. M.O. £300.

London Hospital, Hammersmith, W.—H.P., H.S., Res. Asst., Cas. O., and Aural and Ophth. H.S. Each at rate of £100. Also Radiographer. £250.

ham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £100.

Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons at Aberlour (Banffshire) and Southwell (Nottinghamshire).

rths, Marriages, and Deaths.

BIRTHS.

XLEY.—On Nov. 3rd, at Warminster, the wife of H. L. Blackley, M.D., of a son.

N.—On Nov. 9th, at Riverhead, Sevenoaks, the wife of V. G. Scott Brown, M.B., B.Chir. Camb., of a daughter.

H.—On Nov. 8th, the wife of Dr. A. J. Smyth, Bole Hall, amworth, Staffs, of a daughter.

DEATHS.

LIESH.—On Nov. 9th, at Winchester-terrace, Newcastle-pon-Tyne, Jonathan Dalgliesh, M.R.C.S., L.S.A., late of Vest-parade.

.—On Nov. 10th, Agnes Hood Gray, M.B., B.S., of Welwyn arden City.

N.—On Nov. 6th, at the Old Parsonage, Dorchester, lfred Green, M.R.C.S., L.R.C.P.

EYS.—On Nov. 10th, at a nursing home, Swansea, Alfred effreys, L.R.C.P. Lond., M.R.C.S. Eng.

STONE.—On Nov. 5th, suddenly, at Edinburgh, John arlyle Johnstone, M.D., late of Melrose.

ORD.—On Nov. 7th, suddenly, Sidney Arthur Mugford, .R.C.S., L.R.C.P., of North-side, Clapham Common, ged 65.

E.—On Nov. 11th, at Rue Gambetta, Villefranche-sur-Mer, Vilfrid William Pearse, M.D., D.P.H., late M.O.H. Hong-ong.

AN.—On Nov. 11th, at Southsea, Colonel William Edward liordan (late R.A.M.C.), aged 87.

—On Nov. 13th, at Chantry-road, Clifton, Bristol, Frank erbert Rose, M.R.C.S., L.R.C.P. Lond., aged 71.

r.—On Nov. 10th, at Shepherds House, Marden, Kent, r. Alfred Smart.

PSON.—On Nov. 12th, at Stargill, Kew-road, Richmond, uddenly, Dr. Maitland Thompson, formerly of Hemel Hempstead, Herts, aged 66.

.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

A DISCUSSION ON CONTRACEPTION.

EFFECTS ON THE FEMALE SEXUAL ORGANS.

In the April number of the *Catholic Medical Guardian* appeared an article by Dr. F. J. McCann on the Effects of Contraceptive Practices on the Female Sexual Organs, which has since been reprinted in pamphlet form[1] by the League of National Life, the objects of which are "to combat the theory and practice of contraception (birth prevention), to oppose any form of State or municipal assistance for the promotion of contraception, and to uphold the honour and blessing of parenthood." The article opens with a review of the evidence forthcoming from observations on animals, from which the author concludes that the seminal fluid possesses for the females other than merely fertilising functions. After considering the complex structure and chemical composition of spermatozoa, Dr. McCann writes: "I refuse to believe that in the human species this complex chemical solution—the seminal fluid—containing millions of spermatozoa has no other function than that of providing one spermatozoon for the fertilisation of an ovum" (p. 4). Though the belief that the seminal fluid, apart from its fertilising agency, exerts an influence on the metabolism of the female is not new, Dr. McCann's conception of how this influence is brought about is not the one usually held. After commenting upon the observations of Kohlbrugge that in the mouse, rabbit, and bat spermatozoa may penetrate the uterine mucosa, Dr. McCann says: "It may yet be shown that in the human species spermatozoa do unite and combine with other cells besides the ovum, and thereby exert an important metabolic influence" (p. 4). Later in the paper, however, the author treats the hypothesis above adumbrated as definitely proved. This transition from supposition to affirmation is indicated by the following two sentences: "There is no definite proof as yet available of the metabolic influence of the different components of the seminal fluid, and the special claims made for the prostatic secretion are not only unconvincing but fantastic" (p. 10); and "Thus if the seminal fluid be prevented from being deposited in the vagina, or if so deposited, it be prevented entering the uterus, or again, if it be so altered by chemicals that the spermatozoa are killed, the physiological value of coitus is nullified" (p. 9). The nullification of the physiological value of coitus following the destruction of spermatozoa is not here advanced as a hypothesis; it is stated as a fact. From these two sentences it is clear that Dr. McCann thinks that physiological benefit, apart from fertilisation, is derived by the woman, not from the absorption of prostatic secretion, but from the entry of living spermatozoa into the uterus.

The So-called Malthusian Uterus.

In Dr. McCann's view contraceptive practices injure the woman in two distinct ways. The first depends on the deprivation which she suffers when living spermatozoa are prevented from entering the uterus; the second consists in mechanical and chemical irritation caused to the lower genital passages by the use of contraceptives. "Sooner or later," says the writer, describing the first process (p. 10), "a woman deprived of the full physiological value of sexual union develops important changes in her genital organs .... The changes produced in the uterus cause a slight uniform enlargement, with uniform softening of the cervix and body, which I named the 'Malthusian uterus,' increased loss of blood at the menstrual periods, increased mucoid discharge during the menstrual intervals, together with a certain amount of backache and discomfort. There is likewise an anxious drawn appearance in the woman's face, through the fear of the failure of the contraceptive methods and the fear of pregnancy." Dr. McCann has also observed, as part of the Malthusian uterus syndrome, thickening of the Fallopian tubes, "while there are doubtless changes in the ovaries which will be discovered by further research; but meantime lutein cysts are occasionally produced as a result of contraception, and probably also fibrotic or sclerotic changes" (p. 12). Under the second heading—that of injury to the lower genital passages caused by contraception—are enumerated the following conditions: cinchonism and uterine hæmorrhage attending the use of quinine suppositories; vaginitis caused by douching with alum and lysol solutions (the Malthusian uterus may also be caused by cold douching); uterine and tubal infections caused by forgotten sponge pessaries that have become septic; and cervical lacerations caused by wish-bone pessaries.

[1] The Effects of Contraceptive Practices on the Female Sexual Organs. By F. J. McCann, M.D., F.R.C.S. London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd. Pp. 16. 1s.

The conclusions reached by Dr. McCann in this paper are severely criticised by Dr. F. M. R. Walshe in the July number of the same journal. The Catholic Church, he says, teaches that it does not lie within the province of the doctor to give advice touching the ethical and spiritual life of his patients. In a paper on birth control read before the Guild of SS. Luke, Cosmas, and Damian, Fr. Vincent McNabb stated explicitly that a patient consults his or her doctor solely upon the physiological and pathological issues of the case, and the doctor has no right to use the words "ought" or "ought not" in giving advice, since the ethical category is the domain of the individual's spiritual adviser. Thus, argues Dr. Walshe, the Catholic doctor should confine himself to the purely medical aspects of his problems, and should refuse to allow his judgment thereupon to be influenced by consideration of the ethical value of the practice under discussion. Further, in this particular question, we shall refrain from generalising, with propagandist intent, upon data which the experience of multitudes of women may later prove to be inadequate. Turning to Dr. McCann's paper as constituting "the first attempt to assemble any body of observed facts worthy of serious consideration," Dr. Walshe first comments on the lack of confirmation which this paper has received from other gynæcologists as competent and well placed to observe the effects of contraception as is Dr. McCann. It is then argued that, if the syndrome of the Malthusian uterus is the outcome of seminal deprivation, it should be a matter of indifference whether the lack arises from contraceptive practice or from the denial of sexual activity which is necessarily imposed on all single women—an implication which it would require much courage to push to a logical conclusion. Further, Dr. Walshe has clearly misunderstood Dr. McCann's perhaps somewhat ambiguously-stated views as to the element in the seminal fluid which is of physiological benefit to the woman. Dr. Walshe goes on to say: "On the clinical side let us take the most striking pathological lesion that Dr. McCann attributes to contraception—the so-called 'Malthusian uterus.' We have a slight uniform enlargement and softening of uterus and cervix, irregularity and excess of menstruation, mucoid discharge, headache, and pelvic discomfort. The patient has an anxious and drawn countenance, the alleged expression of her perpetual dread of conceiving. This clinical and pathological state is attributed by Dr. McCann to sexual excitation unaccompanied by the hypothetical effects derived from the seminal fluid. We submit that the indisputable fact is that the lesion and its associated symptoms have nothing whatever specific about them, may be due to causes wholly unrelated to contraception, and occur in women who have never indulged in it. Further, in women who have done so and present this lesion, there is no discoverable relationship of cause and effect. Therefore, in the absence of any reasoned case for the ætiology invoked by Dr. McCann, it is not hard to determine by what familiar paths he has arrived at his conclusion." Dr. Walshe ends the paper by stating it as his view that the Catholic doctor can only contribute honestly and helpfully to the end which, in this matter, the Catholic Church has at heart (namely, the minimisation of contraceptive practice) by being given the latitude to use his influence with his patients in matters of ethical and spiritual import. Indeed, it is well-nigh impossible for the doctor to avoid assuming the rôle of moral adviser as long as it is conceded that psychotherapy falls within his province.

The October number of the *Catholic Medical Guardian* contains further contributions by these writers, the most notable feature of which is a qualification made by Dr. McCann to the conditions under which he holds that seminal deprivation can be harmful to women. This deprivation is apparently only regarded as harmful when the woman's "sexual appetite has been habitually roused and thwarted." Injury would thus not be sustained by unmarried or sexually abstinent married women as a result of seminal deprivation, but only by those women who practise contraception. The "thwarting" of the sexual appetite referred to is clearly not a psychic thwarting, because investigations have shown that in the great majority of cases the woman's orgasm is unaffected by the use of proper contraceptives. The thwarting would rather seem, in Dr. McCann's view, to be of the nature of a biochemical deprivation, in which case it is not easy to see how such deprivation differs from that sustained by unmarried women.

Limitation of Present Knowledge.

From these two papers it is clear that data with regard to the harmfulness or otherwise of contraceptive methods are still conspicuously lacking. It is at present unknown whether, during coitus, spermatic fluid in large quantities enters into the human uterus. It is maintained by some that the os dilates during the orgasm of the woman and that it may then even admit the glans of the penis. Though evidence is available that this happens in certain animals there is at present little to show that it occurs in human beings. The site of absorption of the seminal fluid in genital tract of the female is undetermined; the constitu of that fluid (whether spermatozoa, prostatic, or ot glandular secretion) which in particular has physiolog value for the female, has not been ascertained; it is e disputed whether the seminal fluid is absorbed, in a benefi physiological sense, by the woman at all. Further, evidence propounded by Dr. McCann hardly covers all ki of contraceptives. Thus quinine suppositories are r being displaced in favour of suppositories containing la acid and chinosol. Recently another suppository, spermicidal activity of which is said to depend on evolution of CO_2, has come upon the market. It is as not definitely known whether these suppositories ca harm; neither have their spermicidal powers in vitro b published. The spermicidal action of at least two ki resides in the acid they contain, it being known that movements of spermatozoa are inhibited by acids in concentration. It is not yet definitely determined w degrees of acidity will, in different lengths of time, and different temperatures, destroy human spermatozoa. Furth the degree of acidity which may be achieved, under differ conditions, by the vaginal secretions of women is certainly known, neither has it been established bey question whether acidity may be influenced by constitutio factors, or whether it is always produced by bacteriolog activity alone.

Few responsible doctors would recommend a spo pessary (especially singled out for condemnation by r. McCann), which is notoriously capable of becoming infect to a woman who was not equal to the task of keepin clean; and very few would under any circumstances rec mend a wish-bone pessary. And the fact remains t contraceptives of various kinds are used by hundreds thousands of women who, to their knowledge, suffer harm from them. Moreover, there are not lacking am these, women who admit an improvement in general he from discontinuance of the practice of coitus interruptus liberation from the anxieties which so frequently attend form of birth control. And lastly, even if it were establis that all existing methods of contraception are injurious medical grounds, it would hardly follow that a fool-pr harmless, and certain method was incapable of be discovered in the future.

Beginnings of Research.

It is therefore interesting to learn that research upon subject is proceeding in this country and in America. I recent issue of the *Medical Journal and Record* (New Y May 18th, 1927) will be found an article by Dr. Rob Latou Dickinson, which describes a comprehensive sch of research now being undertaken by the American Bi Control League. In this country a Birth Control Invest tions Committee has been founded under the chairmans of Sir Humphry Rolleston (see THE LANCET, Oct. 2 p. 944) to conduct statistical research upon the efficacy contraceptives now in use in different parts of the wo for this purpose it has prepared a questionaire which filled in in a sufficient number and a sufficient variety cases, will yield that quantity of accurate statist information which is now lacking. This committee is seeking to discover new contraceptive methods free fr the various drawbacks which affect most existing o Any doctor who may possess data likely to yield rel information is invited to communicate with the Secret of the Committee, the Hon. Mrs. Marjorie Farrer, 4 Clanricarde-gardens, London, W. 2.

THE WALTER AND ELIZA HALL INSTITUTE OF RESEARCH.

AN interesting feature of the eighth annual report of research institute at Melbourne is the evidence it affo of constant intercommunication with this country, b through interchange of workers and of material. A chemist from Cambridge has just been appointed and continue studies on hæmoglobin begun in Sir Freder Hopkins's laboratory. The varied and valuable pieces work being carried out include research into the pathol and treatment of hydatid disease, with a survey of o 3000 cases in which complement fixation, intraderm reactions, and precipitin reactions have been done; same tests in bilharzia disease; the immunity reactions fluke infestation in sheep; studies on pancreatic regene tion in guinea-pigs; the bacteriology of puerperal seps the end-results of tuberculous disease of the hip; work on cancer and dental decay. It is clear that work is as wide in scope as it is careful in detail. A g deal of routine serological and biochemical work is carr out, as well as ordinary clinical pathology. During year a hundred new colour preparations were added to museum, and the catalogue was completed. The instit library has also made good progress.

" VICTIMS OF PEACE ": HALD SANATORIUM, VIBORG.

ENMARK, during the war, gave shelter to many English ers and sailors, who, though officially interned as soners of war," were treated as honoured guests. For housing of them and soldiers of other nationalities, ding Russians and Germans, a large camp, with the familiar wooden huts, was established on the great n of Hald, near Viborg, and in a beautiful cemetery guous rest the remains of English victims of wounds or se. A recent publication upon the sanatorium shows the Hald camp was well organised and possessed sub-latest design. The winter climate of Jutland being very severe, the sanatorium has been able to discharge its functions only during seven months of the year; but to enable the work to be unbroken in winter some army huts are being reconditioned, by the provision of double floors and additional outer walls and roofs, the spaces between the old and the new structures being filled with non-conducting peat; central heating, radiators, and hot-water pipes have been installed. The buildings of the sanatorium accommodate some 500 patients, and they are always fully occupied, while on an average 150 patients daily receive special treatment. After-treatment is cared for, the patients on leaving being given full instructions and leaflets telling them how to

Hald Sanatorium near Viborg, Jutland, Denmark.

al buildings, and the sensible decision was reached to t, when it had served the purposes of its origin, into a al for the " Victims of Peace," under which heading cluded especially all those who were suffering from es induced or aggravated by the war, particularly us diseases.

scheme for the sanatorium was initiated by the h Red Cross Society, aided by the State, and the tion is supported by contributions from the county which the patients are sent to Hald and from the " Invalids' Rest " and " Sick Pensions " funds. The ts pay at the rate of about £45 a year for their board. hief affections dealt with are diseases of the joints, of eart, and of the nervous system, and treatment is by the provision of baths of all sorts, massage, actino-y, electricity, and heat, the apparatus being of the " carry on " at home. The dietary, when special food is needed, provides six special diets for specified classes of cases. The patients are enjoined to live out of doors as much as possible; walking is encouraged and gentle games, such as croquet, are indulged in by those who are convalescent.

" Up to the time of my visit," writes the correspondent who has supplied these notes, " between 11,000 and 12,000 patients had been treated at the sanatorium. There is a staff of four medical men with two lay officials. The superintendent is Dr. Brinck Eliassen and the second-in-command is Dr. Hans Soerensen. So far as a layman can judge, from an extended and intensive tour of inspection, Hald Sanatorium is excellently managed; it is worthy of a visit from any British medical man interested in institutional treatment of this character." E. W. R.

RT OF THE INFANT WELFARE CONFERENCE.

report just published of the proceedings of the al Conference on Maternity and Infant Welfare, held ly in the Great Hall of the British Medical Association, ns within its 218 pages the text of all the papers read conference, and a full report of the discussions which rovoked. The subjects dealt with are both of a social edical nature, and include wet-nursing, the incidence ereal disease in antenatal and postnatal clinics, the of artificial light treatment for children under school nd respiratory disease as a factor in infant mortality. eport may be obtained for 2*s.* 6*d.* from the National e for Health, Maternity, and Child Welfare, at Carnegie , 117, Piccadilly, London, W. 1.

OVALTINE RUSKS.

have received from Messrs. A. Wander, Ltd., Manuing Chemists, 184, Queen's Gate, London, S.W., and Langley, Hertfordshire, where the laboratories and are situated, specimens of Ovaltine rusks, which are rom pure wheaten flour incorporated with the Ovaltine food beverage which is manufactured from barley milk and eggs. The rusks are convenient in size, slightly sweet in flavour, and break up easily in the . They should be useful in the feeding of children fants, especially during the period of dentition. For s, toast, trifle, gateau, custard, pudding and other an be made from these rusks, and receipts for such ations are supplied by the makers. The rusks can e used instead of ordinary biscuits, or they can be with hot or cold milk, or with cheese. The varied yment claimed for them by the manufacturers seems uite justifiable.

SUPERFŒTATION.

THE establishment of pregnancy normally inhibits further ovulation, so that insemination does not result in conception until after the young are born. Cases have been recorded from time to time in which it has been supposed that this rule has been broken. The evidence mostly consists either of the presence of one or more conspicuously small young in a litter of rabbits or pigs, or in the occurrence of two parturitions separated by an interval of a few days. Neither is proof of superfœtation, for the growth of a number of embryos is not always uniform, and the two horns of the uterus are to some extent capable of independent action. Several highly inferential cases of real superfœtation in pigs and sheep are, however, recorded[1] by Mr. A. D. Buchanan Smith, and one in particular seems to be satisfactorily proved. A half-bred ewe was in company with a Wensleydale ram up to Nov. 9th, 1926; she then went to another farm where the only ram was an Oxford Down. On March 7th, 1927, she produced two lambs with the characteristics of the Wensleydale Half-bred cross. On April 14th she lambed again; the lambs were quite unlike those of the previous birth and showed clear signs of an Oxford Down sire. The genetical evidence disposes of the possibility of ova lying dormant for a time after fertilisation as they do in some deer. The interval between the parturitions was 38 days, and as the ovarian cycle in the sheep is about 18 days it seems impossible that the two rams should have fertilised ova discharged at the same œstrous cycle (superfecundation). The conclusion is that ovulation and conception must have taken place during pregnancy, and the evidence seems strong.

AN EXTRACT OF VITAMIN B.

THE chemical department of the Institute for Medical Research at Kuala Lumpur undertakes a great variety of work not only in connexion with the Institute itself, but for various departments of Government of the Federated Malay States. In an appendix to the report for 1926 Mr. R. W. Blair describes, in addition to a mass of work in which food and drugs and poisons are prominent, the preparation, by an improved method, of vitamin B extract from rice polishings. Fresh rice polishings of the best quality are sifted from husk and broken rice, and extracted with 20 per cent. alcohol containing 0·1 per cent. of hydrochloric acid; the extract after a week's contact is filtered, concentrated under reduced pressure, further purified, and brought to standard strength. About 4·5 kg. of polishings are worked up daily, and in 1926 over 8600 fluid ounces of extract were prepared for distribution to practitioners, either gratuitously or at the estimated cost of production, for the treatment of beri-beri.

AN UNUSUAL CASE OF LACTATION.

OPINIONS are divided as to the part played by nervous and chemical influence in the initiation of lactation. Endocrinologists hold that hormones formed in the reproductive organs circulate in the blood and stimulate the mammary cells directly. Psychologists lay more emphasis on the signs and sensations of pregnancy causing stimulation of the nerves to the breast through the conscious and unconscious mind. In support of the latter view Dr. W. J. Jago[1] describes an unusual case of lactation in a Soudanese woman, who, though barren, had long wished for a child. Eventually she stole the new-born infant of another woman. This child she nursed at her own breast, which gave a copious supply of milk in spite of the fact that she had never herself been pregnant.

PIGEONS OF THE TEMPLE.

THE *genius loci* who inhabits the Temple has a special influence in promoting good literature. We need only refer to two instances: there is Lamb's well-known essay on the Old Benchers of the Inner Temple in which the particular Elia flavour is most pronounced, and there are all the typical Thackeray passages in Pendennis and in the "Memoirs of Mr. Deuceace," especially Chapter XXX. of the 1849 edition of the former work. The little paper now before us, reprinted from the *Cornhill Magazine* for January, 1921, is written by a medical man, by name Arthur Brebner, who served in the R.A.M.C. during the war, was invalided out of the service, was living in the Temple in 1918, served later as a ship's surgeon, and died from tuberculosis in 1922. The paper is written with a fascinating flavour of Elia and treats of the Temple pigeons as reincarnations of well-known lawyers, both those in real life, such as Blackstone and those of fiction, almost as real, such as Serjeant Buzfuz. Mr. Brebner discourses pleasantly about these birds and their doings, and we think that St. Francis, to whom he refers in his concluding paragraph, would have read the paper with pleasure. We are glad that Mr. Brebner's widow has had the paper reprinted and note that it is to be obtained from Mr. P. Medcalf, the Cloisters, Temple, E.C. 4.

PRESENTS AND "TIPS" IN NURSING HOMES.

To the Editor of THE LANCET.

SIR,—I hope the experience of "Physician's" patient is exceptional. I have been matron of a nursing home for very many years and have always deprecated the giving of valuable presents, whether in money or in kind, to my staff. When consulted by a patient I suggest a box of chocolates or a pair of gloves. It is the recognition of her services, not the value of the gift, that the nurse appreciates. I may add that "Physician" is quite wrong in thinking that it is rich patients that give more liberally. It is the other way about. I am, Sir, yours faithfully,

Nov. 5th, 1927. MATRON.

BANK NOTES AND CHOLERA.

IN North China paper money is used almost exclusively and Dr. H. M. Jettmar[2] thought it worth while to find out how long bank notes contaminated with the cholera vibrio remain a source of infection. A series of bank note slips were contaminated by fingers which had been dipped in a cholera stool. After varying periods of time these slips were put in tubes of peptone water from which, after incubation, further cultures were made. The agglutinability of the vibrios cultured from the infected bank notes was then compared with that of organisms from the original stool. It was found that they remained alive on bank notes for four hours and that they retained the same cultural and serological characteristics as the original strain. Their lives were shortened by lack of moisture on the notes and exposure to sunlight.

SUPERANNUATION FOR LABORATORY ASSISTAN

WE learn with pleasure of a scheme adopted by London School of Hygiene and Tropical Medicine for superannuation of technical and laboratory assistant their employ. Its immediate object is to improve the st of laboratory assistants by placing them on a definite g and scale of salary, which closely follows the lines of Federated Superannuation Scheme for Universities. amount equal to 15 per cent. on the salary, 5 per contributed by the assistant and 10 per cent. by the sch is applied in payment of a yearly insurance premiu secure either an annuity on retirement or a lump under an endowment assurance policy. The schem optional in the case of salaries from £100 to £160 per ann and above that it is compulsory. The scheme has accepted with enthusiasm by the whole of the labora staff concerned, which recognises the value of securit tenure and the opportunities of promotion which it ens provided that similar arrangements become the rule where. We confidently predict that other institutions follow the lead given by the London School.

BLOOD CALCULATIONS.

THE hæmatological nomogram of Dr. E. J. War affords a ready method of calculating the colour index, volume index, and the saturation index of the red cel of the blood. In addition it will give on slight correc the average diameter of the red cells. Up to the pre this nomogram has only been available in the page Dr. Warburg's original communication. It has now published for general use by Levin and Munksgaard Copenhagen. As published the nomogram is mounte a stiff cardboard and provided with a loop by mean which it may be hung on the laboratory wall. It i convenient size so that by the simple application straight edged ruler the desired figures may be read The data required for the use of the nomogram co of the hæmoglobin percentage, the number of red cells c.mm., and the volume of cells per cent. of blood as determ by the hæmatocrit. The general adoption of this nomog should save trouble to those engaged in the study of blood.

THE MODEL ABATTOIR SOCIETY.

THE annual Benjamin Ward Richardson lecture of Society was delivered on Nov. 10th by Dr. Gerald Leigh medical officer (foods), Scottish Board of Health, at Royal Sanitary Institute.

Dr. Leighton said that the problem of the satisfac public health organisation of the meat supply had before all modern civilised communities for years past, all of them had come to certain conclusions which fundamental. In every country it had been realised it was necessary to concentrate the slaughtering of animals in public abattoirs and to make special arrangem for scattered rural districts. It was impossible to main an adequate system of inspection in thousands of s private slaughterhouses. All countries had decided that inspection should be in the hands of well-trained professi inspectors with a knowledge of comparative pathology bacteriology. It was also necessary to have a legal cod judgments of morbid conditions affecting animals used food. Special laws, apart from general food laws, were required to deal with various phases of the industry. the least was it necessary to see that only such method slaughtering as were recognised as being consistent humane methods should be permitted. The essence humane slaughtering in his opinion was the rapid produc of unconsciousness in the animal before the operatio bleeding was performed. Many instruments on the ma were satisfactory when used by an expert, but none satisfactory in the hands of a stupid or careless fool. point was to get humane killing with a good keeping qu of the dressed carcass.

Public abattoirs had been established in Scotland, said Leighton, for two generations, and to-day about 92 per c of the home-killed meat in Scotland passed through pu abattoirs, in which there was a legal system and standar meat inspection established. In his opinion there was little cruelty in abattoirs; there was probably far mor the transit of the animals by land and sea, or in preliminaries before slaughtering. Nor did he think was any cruelty in the open hall system of abattoirs w the cattle could see all going on around them. What ca resented was being dragged through narrow passages, strange places, by unknown people. They would have same objection to being dragged anywhere. He urged importance of public abattoirs from the point of view of t teaching facilities for the trade itself in technical matt and for those qualifying for the position of meat inspec as well, because they were the only places in which all by-products of the industry could be profitably d with.

The Huxley Lecture
ON
DIATHESIS.

elivered at Charing Cross Hospital on Nov. 24th, 1927,

BY SIR ARCHIBALD GARROD, K.C.M.G., D.M., LL.D., F.R.S.,

GIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD; CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

'Men are called healthy in virtue of the inborn capacity easy resistance to those unhealthy influences that may inarily arise; unhealthy in virtue of a lack of that acity."

THIS passage from Aristotle's Categories,[1] written 00 years ago, may well serve as my text to-day. all know what we have in mind when we speak health and disease, but it is not easy to frame initions which shall embrace all that these terms ote. We still need to pay heed to the warning that great teacher, Thomas Watson,[2] that disease st not be regarded as "a thing, or as the phrase s, a separate entity, by which the body is possessed l damaged—something which can be contemplated apart from the body which it may invade."

As Aristotle's definition suggests, the state which call health is one of unstable equilibrium, maintained means of a continual struggle, and no mere escent phase. Thus, in a recent lecture, Andrewes[3] ke of the healthy body as one which "is not only fectly adjusted to its surroundings, but is capable adjusting itself, within reasonable limits, to the umstances of a rapidly changing environment." ease, on the other hand, he defined as "a condi- in which the body has fallen, in lesser or greater ree, out of harmony with its environment." other recent writer, Draper,[4] defines disease as a expression of reaction between a complex set external circumstances, and an equally complex anism striving to survive in the midst of them." narrower definition will suffice to include, as it s must do, such widely different clinical and ological pictures as those of small-pox, malaria, vy, and myxœdema.

is obvious that, as the word implies, disease is ething appertaining to the patient, and is neither invading organism nor a poison introduced. y of the outward signs and symptoms by which recognise diseases are evidences of the struggle h the organism is putting up against enemies h beset it; and as Andrewes pointed out in lecture from which I have quoted, even inflamma- and fever may be regarded as beneficial reactions. erial infections do not necessarily cause disease, "when the body begins to defend itself against k does trouble arise." Nor must we forget, as ave been apt to do in recent years, that not all dies come from without; although the mani- tions of those which do not are often provoked external influences, trauma, exposure, and the

is an indisputable fact, which has been recognised early times, that some individuals, members of families, and of some races of mankind, are nore liable than others to suffer from particular dies; and around that basal fact have grown up various doctrines of diathesis.

or some writers diathesis was nothing more than disposition to this or that malady; for others as itself an extremely chronic disease, which, the hidden mycelium of a mushroom bed, mani- itself here and there, and from time to time, by ard signs. Others, again, gave a wider significance e term, as a liability to a group of allied affections, spoke of an arthritic or a strumous diathesis. held that a diathesis might be acquired, but it was usually regarded as an inborn peculiarity. Lastly, there have always been those who have looked upon the term diathesis as merely a cloak for ignorance, a name masquerading as an explanation.

In medical writings of the first half of the nineteenth century the subject figured largely, and among its foremost exponents in this country were Jonathan Hutchinson,[5] and Thomas Laycock,[6] whose teaching had so wide an influence in the Edinburgh School. The earlier writers claimed as diathetic diseases maladies which, as we now know, have hardly anything in common, some of which are due to bacterial or protozoal invasion, whereas others are due to the lack of some essential factor in diet.

Nor is it to be wondered at that the conceptions of our fathers regarding this subject seem to us obscure, nor that when we read what they wrote upon it we seem to wander in a fog; for when their doctrines were formulated the theory of evolution had not yet emerged; the existence of chromosomes and the importance of the germ plasm were not suspected; the laws of heredity were quite unknown, and hormones and vitamins had not been heard of. We who hold the keys, which they helped to cut, to fields unexplored by them, are well able to appreciate the pitfalls which lay in their path.

The coming of cellular pathology, and above all the growth of bacteriology and protozoology, turned men's minds into other paths. Attention became concentrated upon the agents of disease rather than upon the constitutional factors, which latter received but scant attention; the very conception of diathesis was discredited, and the word itself was relegated to the scrap-heap of obsolete terms, together with such words as "idiopathic" and "strumous."

Now, once more, the pendulum is returning from the limit of its swing; interest in "constitution," which word has, to a large extent, replaced "diathesis" and with a wider connotation, is reawakening more perhaps in other countries than in our own. A large literature in the German tongue has appeared in the past few years, and to Naegeli's[7] writings, and to the work of Julius Bauer,[8] a veritable storehouse of ideas and facts, I would express my indebtedness. In America constitutional clinics are being established, notably that of George Draper, in which valuable work has already been done. In this country Hurst,[9] Ryle,[10] and Maitland Ramsay[11] have, by their discourses, quickened a new interest in the subject.

Despite the fact that in the New English Dictionary diathesis is defined as "a (permanent or acquired) condition of the body which renders it liable to certain special diseases or affections; a constitutional predisposition or tendency," we are little inclined to-day to admit as constitutional states or diatheses, conditions, however long-lasting, which have been acquired; and in this lecture I shall speak of inborn conditions only.

When I was honoured by the invitation to deliver this Huxley Memorial Lecture in Huxley's own medical school, I determined that I would try to sketch the doctrine of diathesis as it appears in the light of recent advances of science, and to emphasise once more the importance of constitutional factors in connexion with the incidence and shaping of maladies. With that aim in view I would ask you to detach yourselves, as far as may be, from the medical standpoint, and to avoid, for the moment, the taking of sides in the struggle between man and his diseases.

There are two main paths by which my subject may be approached: First, by statistical and anthropometric methods, on Galtonian lines. This method is being pursued in Draper's clinic. Draper, who aims at approaching his subject from four different directions—the anatomical, physiological, psychological, and immunological—compares these to the four panels of a Japanese screen, which, although distinct, form parts of a single picture.

The second path is by study of particular examples, and of the light which they throw upon the general

problem. This might be styled an experimental method, but the experimenter is not man but Nature. It is along this second path that I invite you to walk with me to-day.

In pursuit of our inquiry we need to carry our thoughts back very far, to the chromosomes into which, in the words of J. B. Leathes,[12] "are packed from the beginning all that pre-ordains, if not our fate and fortunes, at least our bodily characteristics, down to the colour of our eyelashes." In the illuminating address from which I have quoted, Leathes spoke of the chemical aspect of evolution as follows: "The deposition of matter in molecules or aggregates, unstable or incalculably variable, that has and retains the power of determining the deposition of matter not yet so disposed, in such a way as to conform to its own deposition, or to patterns which help it to exercise this power, is all that must be premised for the whole of evolution to follow." Such a conception would certainly not have been rejected by Huxley,[13] who as long ago as in 1876 said that "to be a teleologist and yet accept evolution it is only necessary to suppose that the original plan was sketched out—that the purpose was foreshadowed, in the molecular arrangements out of which the animals have come."

It cannot fail to be that natural selection works through chemical as through structural modifications, nor can it be doubted that, as Huppert [14] maintained 30 years ago, the features in which an organism differs from type are foreshadowed in the germinal cells, and indeed in the complex molecules of which the germ cells are built up. As evolution proceeds, from the single cell to the nations of such units which constitute higher animals and plants, the somatic cells of which the various tissues are built up become specialised for the several purposes which they have to serve, the renal cells for their work and the hepatic for theirs, and in so doing lose at first part, and later almost the whole, of the power which the primary cells possessed, of reconstruction and repair of tissues; such repairs as are possible are carried out by the wandering cells of the mesenchyme. Only the germinal cells retain the power of reproducing all the tissues and structures of the body, which renders possible the propagation of the species. Whatever may happen to the somatic cells affects the individual, but not the future of the race. Just as in a hive the worker bees are specialised for the carrying out of their appointed tasks, but have no share in the continuation of the race, save in so far as they care for the fertilised queen; so may we think of the somatic cells as waiting upon the needs of the germ plasm.

There is nothing at rest in the living cell, nor in the molecules of which it is composed, nor even in the atoms, with their restless electrons, which go to the making up of those molecules; and in the complex of physical and chemical changes which we call life there are infinite opportunities for departure from type. As evolution proceeds organisms are produced which differ in chemical structure as well as in form, until the proteins of a group of living things become so far differentiated that they behave as foreign proteins to members even of kindred groups. When that stage is reached interbreeding is no longer possible, the species has become established, and its main characters are thenceforward maintained.

As the organism becomes more elaborated there are ever-increasing opportunities of departures from type. As Andrewes says, "a chronometer can suffer from a greater variety of defects than an hour-glass."

Each one of us, and each such departure which he exhibits, is one of Nature's experiments. Huxley,[15] in an address delivered to the International Medical Congress in 1881, after speaking of the vital phenomena which furnish the normal and typical characters of the species, added: "Outside the range of these conditions the normal course of the cycle of vital phenomena is disturbed; abnormal structure makes its appearance, or the proper character and mutual adjustment of the functions cease to be preserved. The extent and importance of these deviations from the typical life may vary indefinitely: they may have no noticeable influence on the general well-being of the economy, or they may favour it. On the other hand, they may be of such a nature as to impede the activities of the organism, or even to involve its destruction."

It is with unfavourable deviations that the study of diathesis is concerned; but if there were no beneficial ones there would be no evolution or advance; progress could go no further; the species could, at best, be saved from regression. Unfavourable modifications tend to be eliminated, because they diminish the capacity of the organism to conform to its environment; and among the factors at work in the elimination of the unfit none is more potent than disease.

A new departure may be both good *and* bad, if the advantage outweigh the disadvantage it may persist. Thus when man assumed the erect position and gave up the hammock-like support of the abdominal viscera which is an essential part of the vertebrate plan, he thereby laid himself open to a number of minor ills, varicose veins, hernia, and the like; but the loss was as nothing compared with the gain, which was no less than the mastery of animate nature on this planet.

Modifications acquired during the lifetime of the subjects, as results of disease or accident, do not come within the scope of our inquiry. That they are not transmitted to future generations a great mass of evidence testifies; they concern the individual only and not his family or race.

Mutations, the steplike variations which originate in the germ-plasm, and are transmitted, are produced by addition to, subtraction from, or alteration in the factors of inheritance already present. The departure from type may be very slight, or so great as to justify the use of the term *per saltum*. Goodrich pictures what may happen to a complex molecule by removal of an atom, or of an atomic grouping, and adds: "In some such fashion do we imagine the changes occur in the factors of inheritance." Lenz [17] carries the same conception a step further and suggests that on a physico-chemical view of the germ-plasm it is not to be expected that it will undergo smooth, continuous changes, but rather that it will be changed in lesser or greater steps, by the removal or shifting of the positions of molecular groupings. I would venture one step further still and point out that we know, from experiments in breeding of Drosophilia, that the same mutation may originate over and over again, in the same species; just as a given chemical reaction will be repeated as often as the necessary conditions are reproduced.

Some mutations are dominant in Mendel's sense and others recessive; but the study of human inheritance on Mendelian lines is beset with many difficulties. For obvious reasons the proportion of normal and abnormal members in the small human families supplies little accurate information as compared with that afforded by the experimental breeding of plants and animals; and we are often driven to apply the knowledge which has been gained by such breeding experiments to human problems, despite the lack of numerical checks.

Thus, albinism, a mutation common to man and lower animals, is shown, by experimental breeding, to be recessive, and the peculiarities of its incidence in man supply clues for the recognition of the recessive character of some other human mutations. We learn that a peculiarity which is wont to appear in several children of normal parents, and with unusual frequency in children of consanguineous matings, may be regarded as recessive. For, as Bateson pointed out long ago, a rare recessive character, to which both parents must contribute recessive genes, is far more likely to appear when parents are both members of a family which can

e recessive factors; and the rarer the anomaly e higher should be the proportion of such matings nong the parents of those who exhibit it. Again, utations which are transmitted through normal nales to the males are regarded as sex-linked cessives.

On the other hand, a character which is handed wn in a family from generation to generation, and ects a large proportion of its members, is probably minant.

Some of the inborn and hereditary characters ich originate as mutations are more obviously ncerned with the structure of parts and others th their functions, and it will be convenient to nsider them under these headings, but not to ume a sharp line of division between them. For indeed, all the potentialities of the future organism ide in the molecular arrangements of the germ-sm, we must assume that even structural anomalies ve a molecular basis; and how greatly chemical tors may modify form is revealed by the study of turbances of the endocrine balance. Keith [18] has phasised this, and not a few zoologists, notably odrich,[19] are prepared to admit the influence of mical factors upon animal structure; but we st be careful not to press such analogies too far, it is obvious that the malformations by defect or ess have little in common with the modifications facial contour and bodily proportions which result m endocrine disturbances.

No two individuals of a species are exactly alike, l even monoval twins differ in their finger-prints; are the differences chiefly in structure. We man beings differ in a thousand ways, in form, in mical life, in mental methods. Of many of the nor differences few of us are even aware, and each is is apt to think of himself as normal. In a mixed pulation such as ours all sorts of factors contribute he average of the race and to its morbid liabilities. e time of life is not without influence; the child his own special maladies, and his points of least stance are not the same as those of the adult. people, too, have their special diseases, and age fers a comparative immunity from others. Indeed, are faced with a problem of great complexity n we attempt to unravel the strands which go to making of man.

tructural mutations are of all degrees. Some are, btless, improvements, some may be classed as nportant, others again are obviously detrimental, some, the most extreme, are incompatible with vival. Minor malformations may be harmful in ue of disfigurement which they cause, or because y increase the risks of accident. When an ortant organ is malformed its function may be aired and so life may be endangered, as witness graver cardiac defects and cystic disease of the neys. Once more a malformed part may prove a *locus minoris resistentiæ;* malformed cardiac valves specially liable to be the seats of malignant ocarditis.

would be easy to collect a number of examples morbid effects of structural malformations, but ry few must suffice. In his book on the "Pedigree Disease," Hutchinson cited spontaneous dislocation alformed joints, and the liability to intussusception ch results from cæcal mesentery. Of far wider ortance is the view put forward by Hurst, who ibutes the X ray appearances of the so-called ertonic and dropped stomachs, with the attendant erences in the gastric secretion, to differences in shape and length of the stomach. But it is some-g more subtle than the influences of anatomical malies which we have in mind when we think of hesis or of constitutional liabilities to disease, and not propose to dwell further upon that aspect he subject to-day.

n the borderland between structural and functional malies lies a large group of diseases of which opose to speak under the name of tissue defects, seeing that they exhibit changes, not in any individual structure or organ, but in special tissues. To one large and important group of these, often spoken of as heredo-familial diseases of the neuromuscular system, Gowers,[20] whose teaching was wont to suggest to his hearers fresh outlooks and new lines of thought, assigned the name of "abiotrophies." Although inborn, the maladies in question do not, as a rule, show obvious signs until after several years of life, and thenceforward are progressive. Gowers pointed out that in some of them at least the nerve or muscle cells wither away, like plants without soil, to be replaced by fibrous tissue, "tissue weed" as he called it. Some of the abiotrophies are dominants, such as Friedreich's ataxia; some are recessives, and pseudohypertrophic muscular dystrophy is a sex-linked recessive, transmitted by normal mothers to their sons.

The period of onset of such maladies is usually much the same in members of the same generation, but there is a tendency for the onset to be earlier from generation to generation. As Mott suggested, in another connexion, diseases which so behave tend to eliminate themselves—a virtuous circle, so to speak—but a sex-linked recessive ensures its own persistence.

The boundaries of the several diseases of the group are not always clearly defined, and examples of more than one abiotrophy are met with in different members of the same family. In some cases of the myopathies defects of individual muscles are met with, and in others areas of change have been found in muscles not obviously involved.[21] Of less importance, save as indications of structural instability, are the miscellaneous malformations which are occasionally met with in association with an abiotrophy.

It has been pointed out by Martius, Julius Bauer, and others, that the abiotrophies are not limited to the neuromuscular system, and we are probably justified in including in this class certain maladies based upon hereditary abnormalities of the blood corpuscles, red and white, and especially congenital hæmolytic jaundice. The brittleness of the red corpuscles in cases of that disease was first observed by Chauffard, and is well known; Naegeli also has observed that the erythrocytes, which in the microscopic field appear to be microcytes, are found, nevertheless, to exceed normal corpuscles in volume; whence he concludes that they are more globular in form.

Naegeli [22] regards the abnormality of the red corpuscles as the primary feature of the condition, which may only manifest itself by obvious signs under the influence of external stimuli such as infections or toxic agents. The hæmolysis and splenic enlargement he regards as secondary phenomena; and it is a well-known fact that the fragility and abnormal form of the red corpuscles persist, in greater or less degree, after removal of the spleen. It should be mentioned, however, that there are those who hold that the primary trouble is in the spleen, and that the abnormality of the corpuscles is secondary thereto. Congenital hæmolytic jaundice is a typical family anomaly, and behaves as a dominant Mendelian characteristic.

As tissue defects may also be classed certain conditions characterised by fragility of the bones. The warning signal of the best known of these is a blue colour of the sclerotics, owing to a defect of the fibrous tissue of the sclerotics which allow the choroidal pigment to show through them. The anomaly has been met with in large numbers of members of the affected families, and in successive generations. As they grow older the affected members, who generally give a history of repeated fractures of bones on slight provocation, tend to develop otosclerosis—an interesting example of the development of a progressive disease, otosclerosis, in the subjects of an inborn anomaly. The fragility would not appear to be due to any deficiency of lime salts in the bones, but to a defect of the mesenchyme, with a disturbance of connective tissue formation.

More recently it has been revealed, by X ray examinations, that in certain subjects the fragile bones cast uniform dark shadows, as if solid throughout, as indeed they are in some cases. The fragility is ascribed to loss of elasticity, and perhaps to loss of tubular structure. The condition which behaves as a recessive character, and has been met with in children of first cousins, with undue frequency, is probably progressive, for various degrees of obliteration of the medullary cavities have been described. In advanced cases enlargement of the spleen and lymphatic glands has been observed, presumably to compensate for loss of bone-marrow.

Of even greater interest, from our point of view, is the strange malady known as myositis ossificans progressiva. This, too, seems to be an anomaly of the mesenchyme, and Bauer suggests that the cells of the mesenchyme retain, in the subjects of this disease, the power, which they normally lose, of producing bony tissue. The bony formation occurs in the connective tissues in and around the affected muscles. Two features of myositis ossificans call for special mention. The first is the association with it, in more than 70 per cent. of all cases, of congenital deformities of the great toes, and in some cases of the thumbs also. The nature of the deformity is not so constant as its seat, but the digits are usually shortened, by suppression of a phalanx or by fusion of phalanges. This association is obviously something quite different from the occasional coexistence of miscellaneous malformations not infrequently met with; but it is difficult to surmise what is the nature of the link between the malformation and the malady. The second point is scarcity of records of hereditary transmission of myositis ossificans. A few instances of its transmission are known, and in one remarkable case a father who had the digital deformities, but no myositis, had a son with identical deformities who developed myositis in childhood.

The tissue defects under discussion bear eloquent witness to the importance of constitutional factors in disease, but they have not in the past played any part in discussions on diathesis. Many of them, indeed, were little known, if known at all, when the earlier writers were occupied with the subject. They teach the important lesson that diseases which develop in later childhood, or even during adult life, may have as their underlying causes inborn anomalies of the germ-plasm which may have been completely latent in earlier life, or may have shown a warning sign, such as blue sclerotics or the digital deformity of myositis ossificans. Nevertheless, they do not conform closely to the conception of diathesis; they are, on the surface, too inevitable.

In the abiotrophies the tissue defects are the most potent causative factors, and the influence of external exciting causes is minimal. It may be that, as Rosenbach suggested, the vitality of the tissues involved is so low that even normal function overtries it. Such evidence as we have, up to now, as to the condition of the affected cells is almost wholly histological, and we do not know whether the trouble be due to some defect in the constitution of the cells themselves or to some abnormal substance in solution in the body fluids. The former appears the more probable explanation, and we possess one clue which may prove to be important—namely, the brittleness of the red corpuscles in congenital hæmolytic jaundice, and their peculiarities of size and form. These are clearly independent of the medium in which they are suspended, and as far as I am aware, it has not been ascertained whether normal red corpuscles are rendered brittle by contact with the serum of a subject of the disease.

On the other hand, it can be established beyond doubt that, in individuals whose metabolic processes are in some way deranged, the presence in the tissues of an abnormal product of metabolism, or of a normal product in undue quantity, may give rise, under adequate provocation, to morbid effects of greater or less gravity. Here, indeed, is realised the underlying idea of most of the earlier conceptions of diathesis or predisposition; as of an intermediate state which, in the words of Germain Sée,[23] "n'est pas encore la maladie—mais qui n'est déjà plus la santé parfaite," and which Jonathan Hutchinson described as "a condition of prolonged peculiarity of health, giving proclivity to definite forms of disease."

In a lecture delivered as long ago as in the year 1855, W. H. Walshe[24] spoke of diathetic diseases as "apparently generated and sustained by an intrinsic blood poison, resulting from some perversion of the nutritive processes of the individual, a suggestion much in advance of the time at which it was uttered; but in the list of diathetic diseases which followed there were no signs of such prescience. In it were included maladies of almost every class.

If we are prepared to look upon the life of animals and plants as a complex of physical and chemical processes, and to recognise the importance of chemical factors in evolution, as was emphasised by Leathes in a recent address, we are bound to admit that the morbid predispositions of human beings depend, to a large extent, upon their chemical build and chemical life. Nor can we escape the conclusion that seeing that differences can be shown to exist, some obvious and some subtle, in the metabolic processes of creatures of different genera and species, there must be differences of like kind, but of less degree, between the individual members of a species.

We should expect chemical mutations to be less obvious than those of form, but it is probable that they are not less numerous. A systematic search for such mutations would involve elaborate metabolic studies of large numbers of individuals, and much of the labour expended would probably be in vain. But just as one who carried out a systematic scrutiny of currency notes would not fail to pick out a note with a wrong watermark, or one printed upon discoloured paper, so some metabolic anomalies attract attention because they give some conspicuous sign, or, as in the case of pentosuria, are detected by response to some routine test in general use.

Some of the more conspicuous anomalies give rise to serious troubles sooner or later; and by the study of the more obvious errors of metabolism we gain insight into the possible effects of such deviations from the specific type; and by learning how a lesion or syndrome is produced in the few cases we may gain a notion of the mode of its production in the many. In most instances the victims of metabolic anomalies show no morbid signs until the appropriate exciting cause comes into play, just as a sufferer from Raynaud's disease may spend his life in the tropics unaware of his infirmity, which is revealed when he comes to a cold climate.

Among the diathetic diseases enumerated by Walshe cystinuria has a place. This anomaly has been known for half a century previously as a cause of calculus formation. We now know that cystin is one of the most important of the fractions of which protein molecules are built up, the bearer of the sulphur which they contain. Cystinuria is the sign of an error of protein metabolism in which other protein fractions are involved. A subject of this anomaly may live his life in ignorance of his infirmity, whereas a brother, similarly affected, may suffer almost continuously from calculous troubles, often in an aggravated form. Cystin, in virtue of its insolubility in acid urine, is eminently suited to form calculi, and given the necessary exciting cause, probably an infection of the urinary tract, the cystinuric will form stones. The presence of the crystalline deposit may favour the infection of the tract. Apart from this the anomaly has no obvious ill-effects, even when tyrosin, leucin, cadaverin, and putrescin are being excreted together with cystin.

Gout may be regarded as a diathetic disease par excellence, and it has found a place in all lists of such maladies. That it is hereditary has been known from ancient times, and it manifests itself by recurrent

roxysms, separated by intervals of apparent alth. Like cystinuria, gout may be described as a agedy of insolubility; for it is hard to doubt that e tendency of uric acid to be deposited in the ssues as crystalline sodium urate is the leading ctor in the attacks, as witness the tophi so often en in the ears of its victims, and not seldom in and ound their joints. Many factors contribute to ovoke the attacks, such as seasonal influences, liscretions of diet, overstrain, and injury; and the its of the lesions are determined by traumata ent or remote, and even the special liability of the e-joint is probably due to the repeated mechanical ults endured by the only joint upon which we ss in walking. Gout in a hemiplegic patient acks the joints of the paralysed limbs. In some mbers of gouty families very trifling provocation fices to determine an attack, whereas in the mune a flagrant combination of all the exciting luences are powerless to do so.

The pathology of gout is hardly less obscure to-day n when my father found uric acid in the blood of ity subjects 80 years ago. The majority of those o have worked at the subject hold that the under- g factor is an error of purin metabolism, but as the nature of that error they do not agree. Others l maintain that the primary fault is one of retion of uric acid, due to a defect of renal function. analogy the former explanation appears the more bable, but the evidence for renal origin cannot be nissed lightly. It is a well-known fact that the retion of endogenous uric acid, which is inde- dent of diet, varies rather widely in different nan individuals, and a systematic study of the unts of uric acid in the blood and urine of dren of gouty parents should yield interesting ults. This much is certain, that in gout we are fronted with a highly hereditary malady, presum- y based upon an inborn defect, the manifestations hich seldom appear before middle life.

he familiar osteo-arthritis of later life, which ears as the hip-joint disease of elderly people, erden's nodes and the like, is often ascribed to an ry, or severe wear and tear, and an infection be a contributory factor. In the great majority stances there is no obvious underlying cause, but few instances at least the primary cause is an r of metabolism. Alcaptonuria, the rare hereditary r of protein metabolism which is characterised by presence in the urine of an aromatic acid, homo- isic acid, derived from tyrosin and phenylalanin, long thought to entail no evil effects. But we know that at the age of about 30 years the ects of this anomaly show signs of blackening of lages, and later in life they develop osteo- ritis. In these cases the articular disease shows liar features, such as a pronounced stoop due to ication of the spine and a characteristic gait, h are sufficient in themselves to rule out a chance ciation, and in some families, notably one which er has described, the joint trouble picked out alcaptonuric members, whereas the normal hers and sisters escaped. Here we have still conclusive evidence that the morbid effects of nborn error of metabolism may be very long poned.

take one more example. It is a familiar fact individuals of the human race differ widely in tivity to light and other forms of radiant energy, hat there have been evolved protective measures, as pigmentation, and to a less extent, hirsuties. reas the available evidence shows that exposure ght is usually beneficial, we also know that in in cases exposure to light gives rise to diseases e skin, and even of the deeper structures also. s been shown, moreover, that the introduction the tissues of certain pigments, for the most fluorescent substances, of which eosin is one, render an individual acutely sensitive to light. pigments of the porphyrin group possess, for the part, this power, and such a pigment is present, in traces, in the tissues and excreta of normal men. It is a tempting hypothesis that these traces may play an important part in connexion with the physiological actions of light and of ultra-violet rays.

In rare individuals porphyrins are present in excess, and are excreted in abundance in the dark red urine and in the fæces. The bones become deeply stained, and the teeth also in some cases. Such hæmato-porphyria is congenital and recessive. Its victims are pitifully hypersensitive to light. When exposed to bright light they develop a skin eruption known as hydroa vacciniforme, which produces deep scars, and brings about grave mutilation by destroying the tissues, blindness, and even trouble in deeper structures such as rigidity of the digits and deformity of the hands. All these troubles may be avoided by protecting the patient from light.

It seems certain, on the other hand, that hæmato-porphyria congenita is not the only cause of hydroa vacciniforme, nor even its commonest cause; but it is significant that when cases of that affection are collated, the sex-incidence and mode of heredity of the whole series closely resemble those of the porphyrinuric cases alone. It seems probable that in the cases without porphyrinuria the underlying cause is some other metabolic derangement, or even several such, and that in the sensitivity of hæmato-porphyrics to light we have a special illustration of a law of wide application.

In the conditions which have been referred to there is present in the tissues some unusual chemical product, or a normal metabolic product in excessive dose, in consequence of an abnormal arrest of metabolism, which arrest is probably due to lack of some individual enzyme, the task of which remains undone. But just as lack of a vitamin or a hormone may bring about untoward results, so it would appear that the mere absence of an enzyme may in itself be the underlying cause of morbid developments. Thus albinism probably results from the lack of the enzyme which brings about the formation of melanin; but a much more striking example is afforded by that grave and remarkable disease, hæmophilia, a typical sex-linked recessive, the essential cause of which appears to be absence of a coagulative factor. Hurst has suggested that constitutional achlorhydria, which is met with in young children, tends to run in families, and was detected by Bennett and Ryle in four out of 100 healthy students, is due to an inborn error of secretion, and I have little doubt that, as time passes, the part played by hereditary chemical defects in providing the substructure of disease will prove to be much greater than, in the present state of our knowledge, it can be shown to be. On the other hand, we need to beware lest such phrases as "error of metabolism," used without real justification, may become convenient cloaks for our ignorance.

The further we pursue the study of diathesis the more clearly do we realise its many-sidedness. New facets present themselves at every step. Of some of these the passage of time forbids me to say anything, and to others I can merely allude. For example, it is by no means easy to draw a dividing line between diathesis and idiosyncrasy. Into the category of idiosyncrasy falls the remarkable hypersensitiveness to particular proteins which is so closely linked up with the causation of urticaria, the erythemata, intermittent hydrarthrosis, and some forms of asthma.

Again, I have said little of the converse of diathesis, the benign mutations which favour the individual in the struggle for existence. Difficult as it is to detect an error of the body chemistry by its evil effects, which may be so long postponed, it must needs be more difficult to detect those which are harmless or have only good effects. Yet we can see how such favourable mutations have been utilised in the building up of the defensive mechanisms which are ready to be brought into play to counteract a poison introduced

and which confer upon some individuals and on the members of certain families an inborn immunity, partial or complete, from various infectious maladies. Nor have I said anything of what Draper calls the psychological panel, the profound influences exerted by and through the nervous system in connexion with what are spoken of as functional maladies, and the instability of the nervous system which is not uncommonly an inherited quality.

Indeed, this lecture of mine is like a jig-saw puzzle, some bits of which have been pieced together, into groups which foreshadow the picture of which they form parts. But if it shall have served to throw any light upon the factors which underlie the conception of diathesis, or shall help to reawaken interest in the constitutional factors which play so important a part in the incidence and shaping of disease, it will have attained its aim. Nor has it been wholly divorced from the practical side of medicine as the healing art; for it stands to reason that the better we understand the susceptibilities of our patients, the better we shall help to stay, what Francis Galton[25] called, "the steady and pitiless march of the hidden weaknesses in our constitutions through illness to death."

CREWE MEMORIAL HOSPITAL.—This hospital is being extended at a cost of £15,000. At the laying of the foundation-stone last week over £8000 was subscribed, and a cheque for £2500 has been received from the London, Midland and Scottish Railway.

UNIVERSITY OF MANCHESTER.—It is announced that the late Prof. Alfred Mica-Smith has left £1500 to found a Dr. Robert Angus Smith scholarship in sanitary science in memory of his uncle. The late Miss Eliza Marple Holt left £600 for the foundation of a scholarship to promote the training of women in medical knowledge, and also left £2385 to the University. A house behind the Public Health Laboratory in York-place has been purchased for this department, which will in future be known as the Department of Bacteriology and Preventive Medicine. The Department of Pathology will be removed from the Medical School and brought into closer touch with the allied Department of Bacteriology. This will leave more room in the Medical School for the extension of other departments. On the recommendation of the Senate and Council it has been decided to confer the title of Emeritus Professor on Prof. R. B. Wild on his retirement from the Leech Chair of Materia Medica and Therapeutics.

SOME OBSERVATIONS ON

LIGHT TREATMENT AT THE LONDO HOSPITAL.

BY J. H. SEQUEIRA, M.D., F.R.C.P. LOND., F.R.C.S. ENG.,

CONSULTING PHYSICIAN TO THE SKIN DEPARTMENT, LON HOSPITAL;

AND

W. J. O'DONOVAN, O.B.E., M.D., M.R.C.P. LO

PHYSICIAN TO THE SKIN DEPARTMENT.

THE Light Department of the London Hospita in two sections: (1) for local treatment; (2) general or light bath treatment. The department the local application of concentrated actinic li originally opened on May 1st, 1900, was extende 1903, and is situated on the second floor of the patient block in a spacious room. The apparatu this section consists of:—

(*a*) Two large carbon-arc lamps (Finsen type) wor at 70 ampères, and arranged to treat four pati simultaneously at each lamp.

(*b*) Four smaller carbon-arc lamps (Finsen-Reyn t working at 25 amperes, each lamp arranged to treat patient.

(*c*) Water cooled mercury-vapour lamps (Kromayer ty

The department for general or light bath treatm is on the roof of the out-patient block, and cons of five rooms with bathroom and lavatory accomm tion. Lamps are installed in four of the five rooms, the fifth apartment is for the use of the nurses and c tains steriliser and examining couch. These ro have been erected as a temporary building to m the urgent need for such a department. The electr equipment of the rooms is as follows:—

Room 1.—Open arc lamp (Finsen type) giving an int white light with a short arc ⅜ in. long. Current requ is 50 ampères, 60 to 70 volts. Direct current is obta from a motor generator, which also supplies the Fi lamps in the light treatment department. The lam suspended on counter-balance-weight gear.

Room 2.—Two open arc lamps (Westminster) workin series off supply company's mains, 240 volts direct consuming 25 ampères each. These lamps give a r violet ray than the Finsen lamps, as carbons burn appr mately 1½ in. apart. They are suspended on counter-bala weight gear, and the whole mounted on a rail to give zontal movement. The arc lamps in Rooms 1 and 2 fitted with metal tray underneath to receive falling ash carbons.

Room 3.—Mercury-vapour lamp (Jessionek, supplie General Radiological Company) fitted on a floor stan complete for attaching to ordinary 240 volts plug in r Consumption 3½ ampères at 240 volts. Mercury-va lamp as above, supplied by Messrs. Westinghouse, Co Hewitt Co.

Room 4.—One long flame Westminster lamp, as in Roo but arranged to be much nearer the floor for the treatm of small children.

All treatment rooms and the nurses' room provided with a system of ozonisers (Quain). room has two hanging pendants, carrying five qu tube generators about 2 in. diameter and a 8 in. long. A high-tension transformer in each r supplies current for these and is controlled b variable resistance switch. The alternating cur to these transformers is supplied by a small ro converter of 240 volts direct current. An ele clock (Synchronome Co.) is provided in each r to show uniform time and facilitate the expo required. All rooms, &c., are heated with hot-w radiators. High-wheeled couches are provided recumbent cases, and the chairs for patients h been specially made with backs arranged with least obstruction possible to the rays.

Illuminants in Use.

No consideration whatever is given to any g enclosed light. Glass is almost impermeable ultra-violet light.

1. Carbon Arcs.—Small or large carbon-pencil are equally valuable if the law in inverse squar

rne in mind—i.e., a small group or single patient aced before a 25 ampère lamp, or ten children or ght adults around a 75 ampère lamp would give ually good results. Such lamps are mechanically pendable owing to their long use by electrical gineers as public illuminants. The only difficulty the regular approximation of the carbon pencils they burn away, and this is efficiently met with any type designed for continuous use. An arc at will burn four hours without replacement of rbons is all that is required. The group treatment patients round an arc lamp is attended by an treme degree of heat and stuffiness which can be ercome by efficient ventilation, or when this impossible, by the installation of an efficient onising apparatus. For convenience of electrical pply two 24 ampère lamps can be used gether as a unit rather than one lamp of higher ipèrage.

2. *Mercury-vapour lamps* have certain advantages. ey are portable and the current required may obtained from ordinary lighting circuits. No chanical attention is necessary during the ordinary of the "burner," which is approximately 1000 urs. It is fragile, replacement is expensive, large-up treatment is impracticable, and the best ults are obtained by treating patients singly, at most in pairs. Great care is needed for the tection of the eyes of both patient and attendant painful conjunctivitis may follow a very short posure. Children particularly require constant tching under this light as they are apt to interfere h the apparatus and get too near the source of it. Accurate timing, which is most important, btained by setting the hands of a cardboard clock e to the time of the termination of the dose, and always having a dependable clock facing the ient who is told that when his time arrives he st leave the lamp. This precaution is taken in e the nurse should by any accident be prevented n giving the necessary warning. We prefer this hod to the installation of an automatic cut-out ked by a clock, since the frequent interruption restarting of the lamp at intervals that may be short as two minutes throws an undue strain on construction, and time is lost in waiting for the ndescent vapour to acquire its full actinic value ach restarting. The reaction from an absolutely lamp is more intense than from one which has n in continuous use for 24 hours, but after that ainly up to 600 hours the reaction has appeared is remarkably constant. When a burner grows the quartz becomes opaque and longer exposures tolerated. When replacing an old burner, there-, it is important to retime the exposures as from start.

Clinical Dosage.

enerally speaking, the initial dose which can be ne with comfort should cause no more than evident reddening of the skin and a conscious ling which is not unpleasant. Three years' erience of initial doses has shown no ill-effects exposures of half an hour to the carbon-arc or of two minutes to a 6-in. mercury-vapour er. With either of these initial doses desquama- in the form of large dry flakes may be wide-ad, or may not occur at all. We have rarely blisters form, however intense the reaction in this timing or however widespread the desqua-ion may have been. From our observation more re reactions are given by the skin of brunettes, also develop far more intense pigmentation as goes on. We meet with blondes whose reaction, rst acute, after many doses is often imperceptible he improvement in their physical state continues. ial dose on a limited area of skin has been suggested a method of determining the dosage for new ents. We have not yet found any disadvantage radually ascending doses from the initial exposure h we have ascertained to be safe—e.g., half an of the carbon arc or two minutes of the mercury our.

The carbon-arc exposure is increased by half an hour at a time to a maximum of four hours per diem. If at any time the skin is noted as being erythematous, with or without pigmentation, the dosage is not increased. In th mercury-vapour cases the initial two minutes to each side of the body is increased weekly by a minute to either side, to a maximum of 20 minutes to each side.

Intermissions due to illness, holidays, menstruation, or other reasons, call for watchfulness. An interval of four days or less calls for no alteration in the time of exposure. A month's rest certainly means a resumption of the initial dosage. After a fortnight's holiday the maximum dose previously reached should be halved, or painful severe erythemata may occur. In practice we find it unnecessary to fix a different initial exposure for children and adults. For rickety babies we have not exceeded a maximum exposure of two and a half hours to the carbon arc. The standard distance of the patient's exposed skin from the source of light is assumed in all cases to be 3 feet, and so far we have applied this system of dosage to every type of disease, but further experience may lead to modifications. It is best to keep the patient still throughout the treatment, and no special advantage is gained by allowing him to walk about. Areas of skin reacting from any local treatment, or ulcerated, are carefully protected by a dressing while the rest of the skin is exposed. If this is not done the patient will complain of pain and discomfort, which is not compensated by any appreciable therapeutic benefit. Protection of the eyes is necessary whenever the front of the body is under treatment. Smoked glasses in practice are always discarded for brown paper masks. Small children wear closely fitting leather and elastic eye-shades in which deep-tinted glasses are inset.

Selection of Patients.

(*a*) *Organisation.*—The choice of patients to be treated must naturally be left to the discretion of the medical officer in charge of the clinic. In practice we find it impossible to take on cases, however suitable, unless and until arrangements have been made to ensure the regularity and continuity of their treatment.

(*b*) *Provision for Regular Attendance.*—The majority of patients needing light treatment will be unable to pay for it during the necessarily long period. Financial aid is necessary if the clinic is to work successfully, and continuity of attendance is essential. In all these matters coöperation with the local authority is of the greatest assistance. In some instances all that is necessary is the provision of a railway season ticket, in others a lodging allowance. The provision of hostels in connexion with clinics attached to general hospitals is now being considered. Attendance of patients can be encouraged by health visitors and by school nurses. Early cases are picked out for treatment by school medical officers, others by tuberculosis officers and infant welfare clinics, while the majority have been and always will be sent for treatment by the general practitioner.

(*c*) Cases of *pulmonary and laryngeal tuberculosis* should be treated only in institutions devoted to this special work, partly because they are contagious and partly because they need special dietary and hygienic care and expert clinical supervision. No surgical case should be admitted unless referred by a competent surgical authority. We have had sent to us cases of spinal caries still needing orthopædic support and cases of rickets that required operative or instrumental correction of deformity. Blood diseases also must be watched by a hæmatologist.

(*d*) *Education.*—The daily treatment must continue for a long time and education must not be forgotten. Illiteracy and indiscipline are bound to occur in children lodged for long periods away from home. Thanks to the keenness of the London educational authorities all our non-contagious children of school age may now attend school for half the day. Arrangements, however, have still to be made for the education of children coming from a distance and living in approved lodgings in the neighbourhood of the clinic.

(*e*) *Reports.*—To secure the willing coöperation of boards of guardians it is necessary to make careful clinical reports which we find it advisable to supplement by photographs. It is obviously to the advantage of the contributing authority to be fully informed of the attendance and progress of cases for which they have assumed responsibility.

(*f*) We never allow ourselves to forget that diseases must be attacked from all sides at once. Rickets calls for dietetic as well as light treatment; lupus needs local as well as general therapy; tuberculous adenitis may need tuberculin injections; surgical tuberculosis may require aspiration or operative measures.

Lupus Vulgaris.

The treatment of lupus vulgaris by the local application of concentrated light (Finsen treatment) has been carried on at the London Hospital for 26 years, and during that period 2663 new cases have been dealt with. From time to time reports on the work have been published,[1] [2] and it will be unnecessary here to give more than a brief summary of the experience gained in the clinic. The cases may be divided into four groups:—

(*a*) Cases in which there has been complete cure with no relapse. A large number of these have been examined periodically, and we are in touch with many that have been well from 10 to 25 years.

(*b*) Cases in which the disease disappeared under treatment, but in which small recurrences have appeared from time to time. In such cases renewed treatment cleared away the lesions.

(*c*) Cases in which the disease improved under treatment, but in which we have never been able to remove all the lesions.

(*d*) A small group of hopeless cases which were not influenced materially by any form of treatment.

In addition to these groups there are patients who, for domestic, financial, or other reasons, have been obliged to give up attending for treatment. Since the first experimental period, in which nothing was used except the light treatment, other therapeutic measures have not been neglected. Superficially ulcerated lesions have received occasional short exposures to X rays. Other measures, such as the application of antiseptics and keratolytic remedies for warty areas, have prepared surfaces for the Finsen treatment. Lesions in the mucous cavities have been dealt with where accessible by curette, cautery, or caustics. Moreover, in gravely disfigured subjects or in areas where the scar is of little moment, the light treatment has been supplemented by the application of acid nitrate of mercury, creosote, and salicylic acid, pyrogallic acid, &c.

As a result of these local measures 70 per cent. of the patients have been cured, 11 per cent. require occasional treatment, 16 per cent. are classed as "improved" and will probably require treatment from time to time all their lives, and 3 per cent. only remain uninfluenced by treatment. These figures are slightly better than those given by Reyn, of the Finsen Institute at Copenhagen, but the type of lupus seen at the great Danish clinic is more severe than that seen in London.

The causes of failure or imperfect response to the Finsen treatment are:—

(1) *Extent of the Disease.*—Many of the patients did not come to the clinic until the lupus had involved large areas. Extensive cases have taken years to cure, and in some instances the surface affected was so great when the patient was first seen that such a slow measure as local phototherapy could not be considered. Where the disease affected large areas on the trunk and limbs—that is to say, parts where the character of the cicatrix was of little importance—surgical measures and the application of caustics like creosote and salicylic plasters were found preferable to the light treatment. Even in some facial cases where there was already great disfigurement it was thought advisable to prepare the way f phototherapy by the application of strong causti It is encouraging to find that in recent years mo cases of lupus of small areas have been sent to t clinic, especially by school medical officers in lar centres, but we still see distressingly mutilated cas from many provincial areas. Multiple lesions of sm size, occurring after acute specific fevers such measles, do not as a rule present difficulties.

(2) *Rapid Spread.*—A very troublesome group cases is that in which the lupus spreads so rapid that it is impossible to keep pace with it by phot therapy. These patients have a very low resistan to infection. Treated areas may heal readily enou but while one site is being cured adjacent pa become invaded and the disease continues to spre The most unfavourable type is that in which there great thickening of the whole skin. When the fa is involved the lips and cheeks become bloated a purplish-red in colour with a form of lympha infiltration resembling a pseudo-elephantiasis. Su cases are not common, but I have followed seve from their early stages and have found nothi influence them.

(3) *Presence of Lupus of the Mucous Membranes.*—In the first report [1] which dealt with a large accum lation of old cases, the proportion of patients w lupus of the mucous membrane of the nose, buc cavity, and pharynx was 43 per cent. Christians gave the proportion of mucous membrane invasio in the Copenhagen Light Clinic at about the sa date as 80 per cent. Mucous membrane lesions w recognised in just under 30 per cent. of new ca seen at the London Hospital. Up to July, 19 these cases were treated by surgical measures, application of strong iodine, trichloracetic ac lactic acid, &c. Some improvement was found follow Pfannenstiel's method of generating nasc iodine in the nasal cavity. In many instanc however, no cure could be effected as it w impossible to reach the whole of the diseased area.

Influence of Light Bath Treatment in Lupus Vulgar.

The light bath treatment was introduced at London Hospital in July, 1922, as an experimen measure on the lines suggested by Reyn. At fi a 25 ampère carbon arc was used and later a la 70 ampère arc with tungsten paste and carbon po was employed. Newer types of carbon-arc a various forms of mercury-vapour lamp were tes and several have been installed.

The first series of patients healed were of resistant type, and light baths were used *without local treatment.* The results were so encouraging th as our resources increased, we combined both lo and general treatment in a large number of cas and found that the efficacy of local treatment w increased by the application of light to the gen body surface. We found (1) that the rapidly extend cases (Type 2) with whose progress we could keep pace by local measures, could be heal and (2) that, as Strandberg was the first to point ou many cases of lupus of the mucous membranes will heal without local treatment. We found, therefo that we had overcome the two chief difficulties wh had previously hampered our work, and thus w able to increase our proportion of cures by 20 cent. We agree with Reyn that a combination local and general light therapy carried out wh proper care in the details of the technique will ra the cures in lupus vulgaris to 90 per cent.

There will always be patients who relapse a months after the treatment has been suspended a they have returned to their normal environme Nothing at present known will permanently ra their resisting power to the *Bacillus tuberculo*. It seems a good practice to give them a prophyla course of light baths every year. There is also a sm percentage of cases that we cannot influence, pa cularly what may be called the "facial lymphati type. Light baths have little or no effect.

Results and Conclusions.

Two hundred and forty-nine cases of lupus vulgaris ave been treated by light baths in addition to local eatment; 16 of them have given up attending for arious reasons, financial or domestic. In one case eatment was abandoned because the patient, who as supposed to have healed fibroid phthisis, had a vere hæmoptysis. One patient, an adult male, eveloped encephalitis lethargica. Four patients died. ne committed suicide after she had left the hospital ; cured ; three died from meningitis.

One was a young girl in whom nasal lupus had been parently cured, and who was suspended from light treatent; another, a woman of middle age, who had extensive eas of dry lupus, was admitted to a Poor-law hospital, d at the autopsy calcareous nodules of stony hardness re found at the apices of both lungs and extensive recent berculous meningitis. The third was a woman, also th extensive lupus of the dry variety of many years' nding. In her case there was no autopsy.

Possibly in all three the meningitis may have been berculous, but in one instance only we have post-ortem information. All these patients had had long riods of light bath therapy.

Reviewing the cases as a whole, the following atements (most of which are generally accepted) pear justified :—

. The results are independent of (*a*) the cutaneous reaction, the extent and degree of pigmentation.

2. Children as a rule improve more rapidly than adults.

3. Increase in the body-weight is small. A rapid decline weight should lead to immediate suspension of light bath atment and a search for active pulmonary invasion.

4. Estimates of temperature and pulse-rates are of no ticular value, but we prefer not to treat pyrexial cases.

5) The very slight leucocytosis observed in early cases , likewise, no clinical importance.

6. There is no doubt of the marked improvement in the neral health of the patients and in their mental outlook. is is independent of any change in the basal metabolism, shown by the London Hospital Clinic.

7. In 26 years' experience I have never seen carcinoma velop in any case of lupus which responded to light rapy. Many of the patients had been under continuous atment by concentration light for years.

In confirmation of these general statements I pend details of cases.

Phthisis Developed and Revealed by Light.

The following three cases show the development of : hæmoptysis ; (2) hilum phthisis ; (3) night eats while under light bath treatment.

ASE 1. *Hæmoptysis.*—T. W., aged 50. Elbow trouble owed injury two years ago. T.B. found in aspirated fluid. ration and vaccine in hospital, 1923. Weak right arm forearm ; sinus, crusts, and scars about ankylosed right w. Several X ray plates not diagnostic. T.B. glands t side of neck 20 years ago. Treated at London Hospital 3rd, 1925, light baths started ; arc light 30 minutes y. 11th : Severe erythema of chest. 18th : Cough, not feel well ; arc light reduced to a quarter of an hour. ch 18th : Hæmoptysis at home ; no further light.

ASE 2. *Hilum Phthisis with Pyrexia.*—L. H., aged 8. admitted a patient Sept. 18th, 1923, with numerous ted multiple tuberculides scattered on the forearm and Microscopically, these lesions were granulomata with inucleate giant cells. The child had a barrel-shaped t, and Dr. Charles Miller, who examined her, considered e was presumptive clinical evidence of enlarged hilum ds. Radiograph showed that the glands around the were excessive for a child of 8. Wassermann reaction tive ; there were no blood abnormalities. Patient was itted to mercury-vapour light baths after her temperature, on observation in the ward, had been normal for a ight. The light doses were gradually increased to a ter of an hour all told—i.e., a quarter of an hour of to each side daily. Her condition became torpid, st typhoidal, and the light baths were suspended on 12th as being definitely harmful. She then immediately tened, but a few new experimental exposures threatened h to make her ill and she was removed by her friends. heard later that she developed pseudo-elephantiasis e leg with tuberculous ulcers.

SE 3.—F. C., aged 31, has had lupus of chin and upper since 1921. July 14th, 1925, light baths commenced. 23rd : Felt very tired, diminished appetite, night ts, loss of voice and weight. Transferred to general ician. Wassermann reaction negative. Numerous T.B. utum. Light bath treatment suspended.

By the regulations laid down by the hospital authorities all the lupus patients who attend the London Hospital light clinic are out-patients. The majority of them live in their own homes or with friends, and their housing, feeding, and general hygiene are, therefore, those of their class. In certain cases where it appears that the food is insufficient, the sister in charge has power to draw upon a small private fund by which children who need them have an allowance of milk and other necessities. Some patients who live at a distance have their fares paid by the local tuberculosis authorities, season tickets being provided in suitable cases. A number of children who come from a distance are housed with respectable women in the neighbourhood, the expense being borne in a few instances by the relatives, but in most by the local authorities. By arrangements with the guardians of neighbouring districts some of the children from provincial areas are lodged in local Poor-law hospitals and attend daily.

It is obvious that the conditions under which these patients live are not ideal and are not to be compared with those of patients who are housed in institutions like Alton and Carshalton. In fact, we are dealing with our cases in what may be considered their normal environment. No one who has any experience of what this environment means can consider the conditions satisfactory, but it would be impossible to alter them except at prohibitive cost. The question of building for our patients one or more hostels where conditions of life could be properly supervised has been raised on several occasions, but the financial position of the hospital does not allow it. The ready coöperation of the London County Council is shown by their spontaneous establishment of a lupus school for boys and girls attending the London Hospital, and this has proved of great assistance.

We have always held that this form of treatment should be carried out in country centres, in clean air and wholesome surroundings, with good food and provision for the education of children. This, however, would entail a large capital outlay and heavy maintenance charges. In spite of all the drawbacks incidental to our out-patient clinic we obtain results which are far better than those obtained before phototherapy was introduced, and in this respect I (J. H. S.) can speak with some certainty, as I had considerable experience of the older measures as applied by surgeons of repute.

THE RESULTS OF
ULTRA-VIOLET LIGHT TREATMENT.

BY ETHEL CASSIE, M.D., D.P.H. EDIN.,
ASSISTANT MEDICAL OFFICER OF HEALTH, BIRMINGHAM ; MEDICAL SUPERINTENDENT, CARNEGIE INFANT WELFARE INSTITUTE, BIRMINGHAM.

THE record of a complete year's work at the Artificial Sunlight Clinic at the Carnegie Institute is now available, and the results can be considered in some detail. The patients are chiefly children under 5 years of age, but a few mothers also receive treatment. Although so much has been written and said with regard to ultra-violet light therapy, the recorded results of special clinics are still few in number, and are complicated by the combination of this treatment with other forms of therapy. The clinic at the Carnegie Institute has been run on the simplest lines and, beyond advice on diet and hygiene, nothing has been done to change the ordinary factors of the child's life. No extra food has been given and cod-liver oil has not been prescribed, though it has not been stopped in the few cases where it was already being administered.

The two lamps are K.B.B. mercury-vapour lamp, the large 440-volt lamp, and the small 220-volt lamp. Most of the work has been done with the large one, which has been used for 439 hours, against 107 hours for the small lamp. The former costs 1·1*d.* per hour and the latter 0·6*d.* per hour for

electricity, but shorter treatments are required with the large lamp. The strength of the lamps in ultra-violet radiations has been estimated regularly, and skin tests have been done in every case. On these factors the dosage has been estimated, and has varied from 3 to 15 minutes per application, given twice weekly.

Rickets.

The value of ultra-violet light therapy in rickets is now generally realised; its speed and simplicity make it invaluable. The difficulty is to secure regular attendance at an out-patient clinic. To illustrate this, it may be mentioned that out of 12 patients in whom rickets was shown by X ray photographs, and whose parents promised regular attendance, not a single one attended. The procedure in rickets is as follows. An X ray photograph of the wrist is taken, and later the child is seen by me at a special clinic where a complete physical examination is made. If the case is suitable and if the mother promises regular attendance, the child is ordered light treatment, the exact dose being prescribed. After about 12 treatments another X ray photograph is taken, and I again see the child, and prescribe further treatment as required. Twelve treatments constitute a course, but in practice 8 to 14 may be given before the second radiograph is taken, the number depending mainly on possible attendances.

For purposes of discussion cases may be placed in three groups :—

(*a*) Completed cases. Rickets shown by X ray, with satisfactory recovery	42
(*b*) Incomplete cases. Rickets shown by X ray, with failure to attend till discharge	77
(*c*) Clinical rickets. Rickets not shown by X ray or no X ray taken	17
Total	136

It may be considered that (*c*) should not be included, but these cases showed definite clinical symptoms—bending, enlarged epiphyses, lack of muscle tone, &c.—and there can be little reasonable doubt that they were cases of rickets. Those who now refuse to accept a case as rickets without an X ray diagnosis are, in my opinion, neglecting some obvious facts. There is definitely a stage in healing rickets where the bone becomes "normal" in X ray photographs, although the child is still suffering from the disease, and may not walk for some weeks longer, and may continue to show other symptoms, such as anæmia, which definitely justify the contention that there has not been a return to normal. Children benefit by treatment at this stage, and should be treated if first seen then. Probably every case of rickets will give an X ray picture at some period of its history, though there is no definite proof for or against this. It is conceivable that the changes usually seen in radiographs are gross ones which are not necessarily present in every case of a generalised metabolic disturbance, the incidence of which may fall with varying degrees of severity on different tissues.

The attendances of the completed cases, Group A, were as follows :—

Cases.	Attendances.	Cases.	Attendances.
16	10–20	4	40–50
15	20–30	2	50–60
5	30–40		

Many cases attended after the radiograph showed normal bones, as the muscle tone and general health remained defective.

The order in which improvement appears normally to occur is as follows :—

(*a*) Improvement in disposition. The child is more cheerful and contented, and sleeps and eats better. This change is often very marked, and induces the mothers to continue attending.

(*b*) Improvement in the radiograph picture, and eruption of teeth where there is delayed dentition.

(*c*) Improvement in muscle tone.

(*d*) Improvement in anæmia when present. This is always delayed. The hæmoglobin percentage remains low for some time, and rises slowly. The number of erythrocytes increases earlier than the rise in hæmoglobin percentage.

Deformities naturally tend to improve very slowly. Flat-foot is often troublesome. Many of the children were sent to the remedial exercise clinic when the mothers could be induced to attend.

Analysing all the cases, it was found that 62 had made a series of continuous attendances till the bones became normal.

Cases.	Attendances.	Courses.
32	8–14	1
27	14–28	2
3	48–49	4

It will be seen that in the large majority one to two courses of treatment suffice to produce a normal radiograph; only the very severe cases require prolonged treatment.

The total attendances for all cases were as follows :—

Group.	Cases.	Attendances.	Average attendance.
A	42	1021	24
B	77	1088	14
C	17	197	12

Ætiology.

An endeavour was made to ascertain as far as possible the cause of the condition. The mother was carefully questioned and it became fairly easy to decide the predominating factor, which was generally "bad hygiene," as is seen in the table below. This means insufficient fresh air and light not necessarily bad housing, although this was present in the majority of instances. The important point was that the child was never out of doors much, either because the yard was considered unsuitable or there was no yard, or the mother was careless or unhealthy, or the child was too zealously guarded from the weather owing to some ill-health. "Defective diet" means a diet worse than the average and especially deficient in milk. These cases come from extremely poor families, and the children are fed mainly on bread and margarine. Ill-health certainly plays a part in the causation, often in relation to confinement to the house, but also apparently apart from this, though it is difficult to distinguish cause and effect in every case.

Prophylaxis.

From July an attempt was made to induce mothers with young, healthy infants, living under particularly bad housing conditions, to bring the child for weekly treatment in order to prevent the development of rickets. The children, who were all under 6 months of age, were seen by me and their physical condition noted: none had "clinical" rickets. There was no bending, enlargement of the epiphyses, loss of muscle tone, &c. Pallor was noted in three or four cases only. Forty-six infants were brought up chiefly during the autumn months. After the medical examination an X ray photograph was taken, and in five cases the presence of active rickets was reported—i.e., in 10 per cent. of apparently healthy infants under 6 months, living in bad hygienic conditions and showing no symptom of ill-health beyond pallor. The numbers are small, but they are certainly suggestive. Unfortunately it was impossible to obtain regular attendance; 29 attended less than five times, and only two completed the winter.

The small numbers make it impossible to say whether a weekly treatment with ultra-violet light would be sufficient to prevent rickets under bad hygienic conditions, but my personal impression is that it would, on a fairly satisfactory diet, without cod-liver oil.

Other Conditions.

A complete table of these cases is here given. Classification is difficult, but has been done as carefully as possible. Regular attendance is frequently unobtainable, and this reduces the available number when considering effects. Among the most encoura

results were those obtained in "debility following infectious diseases" and in "catarrhal children." "chronic bronchitis" cases vary; on the whole treatment is worth trying. The "infantile zemas" did well, especially the type affecting flexures as sites of election. The patches were posed for three to six minutes at 18 in., where best results were obtained. The relief from ritus and the rapid drying of "weeping patches" es great relief to the child, but even after clearing the condition tends to recur, and often remains tionary in the dry stage for some time. No local atment, except boro-calamine lotion, was used the same time. These impressions are gained not y from the tabulated cases, but from those more ently treated. There were only two cases of erculous peritonitis, but both these did very well. general debility group is a very large one. The jority were children from bad homes, badly cared and their attendance was poor. They form an atisfactory section, and have been placed under subgroup "mismanagement." The others in group did much as one would expect. The tarrhal" cases, including enlarged gland cases, roved markedly. The "nervous child" type did benefit at all. An interesting subgroup were the children with "very poor muscle tone." They no definite symptoms of rickets apart from this the radiograph showed "normal bones," but r rapid and invariable improvement with ultra- et light suggests a relationship to rickets. Some he worst cases were unable to sit up or stand.

nother series of some importance was the ctation" group. Nine mothers attending the st-feeding clinic, who had deficient milk, were n ultra-violet light treatment, although the y was sucking well. These women had failed improve with ordinary advice as to diet and agement. The milk did not improve, although majority stated that they felt better in health.

Conclusion.

f the value of ultra-violet light treatment for ts there can be no question; improvement be obtained rapidly and surely in all cases. cases with a strong catarrhal tendency, or lity following infectious diseases, including monia, show marked improvement. It is useful infantile eczemas and in alopecia. The results ng children treated in the observation ward of institute and given light treatment are similar. ted infants suffering from chronic dyspepsia various causes do not, however, benefit to any ed extent. Even in these, however, the use of treatment is valuable in order to prevent the of rickets.

INDUCTION OF PREMATURE LABOUR

AND ITS JUSTIFICATION.

By G. W. R. THOMSON, M.B., B.S. Lond.,
FORMERLY OBSTETRIC HOUSE PHYSICIAN AT ST. THOMAS'S HOSPITAL.

THE arguments brought forward against the operation of induction are: (1) the increased risk of sepsis by the introduction of a foreign body into the uterus; (2) that the preliminary interference and period of waiting for labour to begin induces a state of mind in the expectant mother unfavourable to physiological parturition; (3) the risk of a premature infant being born, with a poor expectation of survival; and (4) that the pelvic calibre is not fully exploited.

The first and third points will be examined in this paper. The second is difficult to estimate, and all that can be said in regard to it is that the impression among the medical and midwife staff in charge of our patients is that the mental effect is not appreciably noticeable. The fourth point holds good in a certain proportion of cases, but should become less important with more careful examination and increasing experience in the selection of cases and of the time of induction.

Of the cases subjected to induction of premature labour in the maternity ward at St. Thomas's Hospital in the six years 1920–25, those in which the operation was performed for albuminuria and the toxæmias of pregnancy are put in a group by themselves because their lowered resistance introduces a factor increasing the morbidity-rate and invalidating comparison with the general morbidity-rate. In the first group the indication for terminating the pregnancy was chiefly that of disproportion between the fœtal head and pelvis, but the group contains also a few cases of maternal cardiac disease. In the second group the indication was renal inadequacy or toxæmic symptoms either of serious degree or not yielding to treatment. Induction for placenta prævia falls into another category altogether and is not comparable to the ordinary induction adopted to avoid a difficult and protracted labour. It has, therefore, been excluded from the series.

The Strasbourg standard of morbidity is the one adopted in the ward—i.e., a temperature of 100·4° F. (38° C.) or over for 24 hours. Some of the cases have been subjected to other internal manipulations, such as forceps delivery, internal version, bimanual rotation or introduction of de Ribes's bag, which increase the risk of morbidity, and such measures have been noted whenever possible.

The total number of inductions in the two groups amounts to 146 cases in the six years under review, 102 falling into the first group and 44 into the second. These numbers occurred in a total of 3600 patients admitted to the ward, or a percentage of 4·08 of the whole and 2·8 for the first group alone.

In Table A, among the 102 non-albuminuric cases, there was one death from puerperal insanity, the patient, on the night after her delivery, jumping over the ward balcony; there was no previous rise of temperature or other evidence of complications. Of the three pyrexial cases one had an unexplained pyrexia of 104° F. for 36 hours two days before labour commenced and three days after the bougies were introduced, one had a short pyrexia of two days occurring three days after delivery for no apparent reason, and the third had broncho-pneumonia after four anæsthetics for operative procedures. The morbidity-rate for this group is 3·92 per cent. One patient had hallucinations for three days and then recovered completely; there was no accompanying pyrexia.

There was also a case of subacute mastitis associated with an acute coryza and a temperature of 102° F., 100° for 48 hours arising on the twelfth day of the puerperium.

In Group II., covering those cases of disorders associated with pregnancy that might lower maternal resistance, all save one fell into the category of

albuminuria or toxæmia of pregnancy. The exception was a case of advanced carcinoma of the rectum with secondary peritoneal metastases. Among these there were two deaths, one from uræmia and the other from septicæmia, and three pyrexial cases that recovered; two had pyelitis and the other septicæmia, the latter

being transferred to a fever hospital with mumps. The morbidity-rate in this group is 11·3 per cent. In the two groups together the rate is 7·1 per cent.

The general morbidity-rate for the ward in the year 1924 worked out at 6·8 per cent., so that these figures indicate that the fear of increased risk of sepsis from induction is unfounded, though the number of cases is admittedly too small for dogmatic statement. Of the cases in which labour was induced for disproportion the morbidity was considerably less than the average of all cases in the ward.

Effects on the Child.

In the 102 cases in the first group there were 12 stillbirths, 4 premature, and 8 apparently mature. Of these two were macerated fœtuses. Prolapse of the cord was present in two cases and was treated by the de Ribes's bag in one and internal version in the other; another case was a brow presentation and craniotomy was performed. There was no clear reason why the infants should have died during delivery in the other cases, and we have no explanation to offer for the high stillbirth-rate in this group—more than three times the average. On the other hand, all the premature infants were discharged from the ward in a normal condition, taking the breast well; most of them were of 37 weeks' intra-uterine development or more; a few were 36 weeks; one was 33 weeks and did very well, showing that apart from the increased risk of stillbirth the rearing of the slightly premature child presented no particular difficulty.

Of the 90 infants born alive in Group I. 73 have been "followed up" since leaving the ward, and the mothers of 17 have not replied to letters of inquiry sent to their homes by post. Out of 73 premature infants who left the ward in good health and whose history is known five died in the first year of life: (1) from erysipelas, aged 3 weeks; (2) from renal thrombosis, aged 4 weeks; (3) from marasmus, aged 4 weeks; (4) died at 4 months, cause unknown; and (5) one of twins died at the fifth week, cause unknown. Sixty-eight are now doing well and no difficulty occurred with breast-feeding, except with one at 36 weeks' maturity, which, after being fed by the spoon with expressed milk for one month, eventually took the breast well.

Whether the operation was justified or not can be determined in each case by taking into account the effect of the parturition on mother and child. An attempt has been made to obtain an index of this kind by taking the length of the second stage of labour together with the degree of moulding and extent of the caput succedaneum on the fœtal head. These criteria must be modified by taking into consideration the strength of the pains and the size of the head. Naturally, if the child was stillborn, with intracranial hæmorrhage and gross signs of pressure, the choice of operation or the time at which it was performed was wrong.

Unfortunately the records in our series are not as full as we should have liked, but the following figures show that on an average the labours were not abnormal and that there was an undoubted tendency to induce labour too early or unnecessarily. Of the 102 cases in Group I. 30 labours were over two hours in the second stage and 10 of them over three hours. The forceps was applied, usually for weak pains with the head on the perineum, in 13 cases, and there was one perforation for a brow presentation. In only five cases was excessive moulding of the fœtal head noted.

The method of induction is that of inserting two or three Krause's No. 12 bougies between the membranes and uterine wall, due aseptic precautions having been taken, and the cervix being drawn down to the vulva by ovum forceps and thoroughly cleaned with a 2 per cent. spirit solution of iodine.

The following cases are quoted as examples, the patients having been in the maternity ward for two or more confinements.

CASE 1.—First child (home), 1920. Term. Difficult labour with forceps, R.P. bleeding and stitches. Baby said to be 11½ lb.; did well. Second child (St. Thomas's), 19... Labour induced at 36th week for disproportion. Baby weighed 5 lb. Second stage one hour. No excessive moulding. Puerperium normal. Feeding somewhat difficult for first month; after that easy. Third child (St. Thomas's), 1924. Induction 38th week. Baby 7 lb. 8 oz. Labour easy. No morbidity. Manual removal of placenta. Fourth child (St. Thomas's), 1926. Examined several times before term and breech presentation moved to vertex. After examination under anæsthesia, it was decided to let patient go to term. Labour commenced roughly three weeks before expected time. R.O.A. Second stage one hour two hours. Forceps. Baby born asphyxiated. Large caput; much moulding; died in two hours. P.M., small pallor cerebellar hæmorrhages. Weight 7 lb. 8 oz. No signs of external injury. Delay due to imperfect flexion and œdematous anterior lip of os.

CASE 2.—First child (St. Thomas's), 1914. Term. Forceps. Child lived; had congenital dislocation of right hip. Second child (St. Thomas's), 1921. Induction for disproportion. Patient had right scoliosis of the spine and the diagonal conjugate was 4 inches. Easy labour. Child 6 lb. 8 oz. and mature. Third child (St. Thomas's), 19... Induction at 33rd week for disproportion. Scopolamine narcosis. Baby was a "morphine child," but did very well and weighed 5 lb. 13 oz., and the diameters of the head were about ½ inch below the average.

Case 2 would seem to indicate that there are other factors besides the size of the fœtal head that influence the estimation of disproportion, as the 1923 child was smaller and weighed 9 oz. less than the 1921 child. The decision in our cases has always rested on the fit of the head into the brim of the pelvis as estimated by Munro Kerr's modification of Muller's method, and this may be influenced by the position and flexion of the head to a marked extent.

The majority of multiparæ who had premature labours induced had previously been through one or more difficult labours with forceps deliveries, frequently resulting in stillbirth. The primiparæ are those in whom at the 36th week the fœtal head had not yet sunk into the pelvis. These cases are then submitted to examination under anæsthesia and the head is pushed into the pelvis with one hand while the internal fingers indicate the direction in which the forceps is applied and estimate the descent of the head. If the head cannot be pushed halfway down the back of the pubic symphysis induction is performed. In these cases in which the disproportion seemed marked an easy labour often occurred with no excessive moulding; the tendency is therefore to induce labour too early. The explanation is that, whereas in labour we have a strong steady push lasting over several hours aided helped by moulding, these factors are not present in examination. Thus considerable experience is required to make an accurate decision.

CASE 3.—First child (St. Thomas's), 1920. Induction at term for disproportion. Diagonal conjugate 4 inches. Second stage two hours. Child 7 lb. No morbidity.

nd child (St. Thomas's), 1921. Induction at 38th week disproportion. Second stage under two hours. Child 5 lb.

ASE 4.—First child, 1920. Induction in City of London pital. Reason not given. Child living. Second child Thomas's), 1924. Induction 39th week. Child weighed 3 oz. Easy labour. Third child (St. Thomas's), 1926. gonal conjugate 4¼ inches. Spontaneous delivery after nd stage of four hours at 39th week; child weighing 8 oz. Measurements of head ¼ inch subnormal. iculty due to œdematous lip of cervix.

With the advance of midwifery during the last years the rôle of the physician has undergone a at change. Formerly the medical attendant was uired to show his skill and often his muscle power delivering the child, the relatives and monthly se taking complete charge of the pregnancy, rperium, and rearing. At the present time his es involve a careful supervision of the pregnancy, rder to make the labour proceed with as little rference on his part as possible; also the direction he puerperium and the bringing-up of the child.

The "Trial Trip."

here are two different schools of thought about niparæ with some disproportion of size between fœtal head and pelvic brim. One is that the labour should be used as a "trial trip" in order nd out whether the pelvis will accommodate and smit a fœtus of average size at full term. If it and high forceps or the perforator have to be l, the next pregnancy is watched with greater care induction of premature labour carried out at the t period of gestation.

he other aims at producing a live infant at the first inement by inducing when the head seems to be ost too large to pass through the pelvis. The ent is examined weekly in the manner above ribed and when the fœtal head can only with culty be fixed in the pelvic brim labour is induced. es of the labours are taken, so that when the an presents with a second pregnancy it is known y accurately whether her pelvis will transmit a time fœtus of average size.

here seems to be nothing to commend the first hod, either medically or from the woman's point iew, and the second seems the more rational one. in successful use in the maternity ward at St. nas's Hospital. Each case of induction is ded in the following manner.

SE 1.—Primipara, aged 19. Expected date of delivery 14th, 1926. Extract from antenatal card: "Presentation A. Measurements: Intercristal, 10¼ inches; inter- us, 9¼ inches. Breasts normal. Urine: No albumin gar." Sept. 14th: Fœtal head high above pelvic brim. onal conjugate, 4 inches. 15th: Anæsthetic; diagonal gate confirmed 4 inches; head not made to enter c brim by Munro Kerr's method; induction; bougie quinine. 20th: Labour, first stage, six hours; second , four hours. Child: Large caput succedaneum, much ding; weighed 5 lb. 13 oz.; head passed through brim anterior asynclitism. Puerperium, no morbidity. ution normal. Conclusion: Induction justified.

SE 2.—Primipara, aged 24. Expected date of delivery 5th, 1926; antenatal observations: Presentation A. Measurements: Intercristal, 10½ inches; inter- us, 8½ inches. Sept. 21st: Head high; can be made nter brim with difficulty. 28th: Same remark. : Anæsthetic. Diagonal conjugate, 4½ inches; true gate, 4 inches. Munro Kerr: Head can be pushed y halfway down the back of the symphysis pubes. ction; bougies. Labour commenced in 12 hours and 12 hours. Baby, mature; 19¼ inches long. Measure- of head normal. No excessive moulding; no large . Puerperium and involution normal. Conclusion: an average-sized fœtus induction not required.

the bones of the skull in a premature fœtus do protect the brain from pressure during the second of labour as well as those of a full-time child better when in doubt to induce labour early and avour to shorten this stage and lessen the chances tracranial injury. If the weight of the child is e neighbourhood of 6 lb. at birth there is usually difficulty in rearing it.

m very grateful to Dr. J. S. Fairbairn (St. Thomas's ital) for his kindness and help with this article.

THE "TONSIL" QUESTION.

By FRED STOKER, M.B., F.R.C.S. Edin.,
SURGEON IN CHARGE OF THE THROAT, NOSE AND EAR DEPARTMENT, QUEEN MARY'S HOSPITAL FOR THE EAST END, ETC.

THE purpose of this contribution is to inquire whether the wholesale removal of tonsils is justifiable.

Under the general term "tonsils" are included the pharyngeal tonsil, usually spoken of as "adenoids," the faucial tonsils, and the lingual tonsil, and the scope of the inquiry is limited to the chronic conditions of those organs described as hypertrophic, septic, infective, &c. There is a common tendency to condemn tonsils simply because they are enlarged, and no less common is the inclination to saddle them with the blame of an obscure toxæmia for which neither the teeth nor the intestines can be held responsible. One is often asked, by anxious yet optimistic parents, "Is it the tonsils?" when they are dissatisfied with the intelligence, the physique, the speech, or even the habits of their progeny. The tonsils are constantly removed on such grounds, the surgeon being warmed by the comforting thought that if the operation does not prove beneficial, it will, at any rate, do no harm. Do we exercise the same care and discrimination before advising the removal of tonsils which we observe when recommending, for example, a radical mastoid operation? Do we go into all the possible reasons why the tonsils are enlarged, or ask ourselves if the cheesy contents of an open crypt are indeed harmful?

A consideration of the position, structure, and function of normal tonsillar tissue will provide food for thought. Briefly, the tonsils are aggregations of lymphoid tissue, covered by the epithelium of the part, penetrated by surface-opening crypts, and situated at the portals of the alimentary and respiratory tracts. They differ from lymphatic glands not only in their superficial position and in the absence of afferent lymph-vessels, but also in the fact that they contribute mucus and a reducing substance to the saliva. The building up of the tonsils coincides significantly with the period of most rapid body growth. The epoch in development in which infections are most dangerous, and before full resistance to their invasion has been attained, is the time when the tonsils reach the acme of their evolution. This accession of lymphoid tissue is very important for two reasons. First, because it reinforces the protective mechanism by increasing the leucocytes; secondly, because it stimulates local growth, for, according to Carrel, the rate of proliferation of epithelium and connective tissue cells is increased by the presence of neighbouring colonies of lymphocytes.

Tonsillar Hypertrophy in Malnutrition.

Tonsillar hypertrophy may therefore, in the early years of life, be entirely protective; it may also be an indication that body growth is not being well catered for, and that it is serving in a compensatory capacity. It is a matter of every-day observation that badly fed children, and those nurtured in unfavourable conditions, more frequently exhibit enlarged tonsils than do those brought up in a better environment. This applies both to rich and poor. Clark found that a high fat and carbohydrate diet increased the size of the lymphoid areas both in the throat and in the intestine. Stucky was impressed with the relation between the hypertrophied tonsils in the children of Kentucky mountaineers and their de-vitaminised diet, and he observed how these children showed no appreciable benefit after operation if they were kept on the same food, but gave a marvellous response to a diet of milk, eggs, butter, and wholemeal. This association of improper diet and hypertrophied tonsils has been noted and inquired into by many other observers, and I have no doubt of its importance. Many children are given too much sugar and highly milled grain; in houses where there was no possible justification for such economy I have seen, again and again, children given for their

mid-day meal potatoes and gravy, followed by milled rice. Wholemeal, whether it be wheat, oats, or rye, green vegetables, raw fruit, fat-soluble A foods (milk, butter, eggs, &c.), and an allowance of meat as a diet would, I am convinced, lead to an enormous shrinkage in the number of hypertrophied tonsils and adenoids.

Whether non-pathological hypertrophy be of protective or developmental significance in a particular case, the error of removing it is evident. Bauner and Orpel state that, of healthy children who were subjected to tonsillectomy, 57 per cent. were in "poorer condition" after the operation. Kaiser, of the Mayo Clinic, found that 22 per cent. of 5000 children who had had no previous glandular mischief had definitely enlarged glands one year after operation, though he does not state whether this was compensatory or due to an infective agent. Sluder and Zahorsky are both of opinion that tonsillectomy in early life induces a predisposition to infections, while J. E. Davis affirms that he has most convincing evidence of the development of atrophy or hypertrophy of the nasopharyngeal mucosa, of atrophic rhinitis, and of otosclerotic degenerations when tonsillar tissue was removed too early. Such changes, indeed, would naturally follow a deprivation like this if Carrel's conclusions are correct.

The Ill-effects of Pathological Tonsils.

A tonsil may be harmful, locally or systemically, on account of its size, or because of its focal infectivity. Among the mechanical effects of hypertrophy are nasal obstruction and all that it entails, facial deformity, otitis media, dyspnœa, maldevelopment of the chest, and defective oxygenation of the blood. The list of results which have been ascribed to an infective focus in tonsillar tissue is colossal in length and catholic in selection. The local disorders for which such infectivity is responsible include recurrent tonsillitis, "relaxed throat" (which I understand to be an œdema of the faucial pillars, uvula, and pharynx), peritonsillitis, purulent and simple rhinitis, sinusitis, retropharyngeal abscess, and inflammatory conditions of the Eustachian tube, middle ear, pharynx, and larynx.

The general effects, which may be looked upon as those of chronic sapræmia or septicæmia, appear to be most commonly directed at the muscles, joints, heart, blood, and alimentary system, though chorea, nephritis, and inflammatory affections of the nose and eyes are almost as frequent. The ductless glands are involved less often, though the part which infected tonsils can play in the causation of toxic goitre is well appreciated. Barnhill states, for example, that 90 per cent. of his goitre cases had diseased tonsils; Crile, Halsted, and Mayo remove the tonsils, if diseased, after operating on the thyroid, while Joseph Beck removes them before the thyroidectomy.

In this connexion it must have occurred to many that the "adenoid facies" was not entirely due to nasal obstruction; the open mouth, short upper lip, and badly developed nose and palate *may* all be consequences, but the vacant look, the weak hair, the suggestion of an insecure union between the head and the spine, and the under-development of the skeleton and the lack of intelligence and power of concentration suggest defective pituitary and thyroid action. This *may* be in relation to infected tonsillar tissue. Citelli has stated that there is an anastomosis between the small veins and capillaries of the nasopharynx and those of the hypophyseal region, and concludes that the pituitary may be infected through this medium. Even without this direct connexion the pituitary may be infected in the same way as the thyroid—viz., through the blood stream—and it is interesting to note that both the pharyngeal tonsil and the pituitary are functioning most actively in early childhood. On the other hand, the deficiency may be quite independent of such relationship.

To determine whether or not the condition of the tonsils is responsible for systemic disease is not such a simple matter as would at first appear. It is as well, in any case giving rise to uncertainty, to ascertain whether the disorder is in fact of the "infective" type or not. A cell count should elucidate this; if there is a chronic infection, the blood examination will show either a lymphocytosis or a leucopenia. The alteration from the normal may not be impressive, and there is a difficulty in determining the latitude the pathologist allows himself in describing variations of cells as "within the normal." If, however, the departure from the usual, no matter how small, is fairly constant on three examinations it will be safe to act on it.

The Implication of the Tonsils.

It has been established that living organisms cannot pass into the substance of the tonsil if the epithelium lining the crypts is intact. The clinical manifestation of ulceration of this protective layer is, I take it, enlargement of the associated cervical glands. Based on this argument many authorities hold that general symptoms can only arise when this ulceration of epithelium has taken place, but, personally, I cannot agree that colonies of bacteria in intact walled crypts are innocuous. If the drainage of the crypt is perfect, then probably no harm will result; crypts, however, by reason of their shape, are not readily drained, particularly if there is associated fibrosis. Other organic chemical substances are readily absorbed through the mucosa of the upper respiratory tract; why not toxins?

While a rapid inspection of the fauces with a tongue depressor may be sufficient to note superficial appearances, such a means of examination is generally inadequate. It is necessary to look at the adenoids with a post-nasal mirror or nasopharyngoscope, ascertaining the size and position of the mass and noting any discharge issuing from its pouch, which may be looked upon as the analogue of a crypt in a faucial or lingual tonsil. The shape of the nasopharynx and appearance of the choanæ are also to be noted.

The faucial pillars having been scrutinised for signs of inflammation, the faucial tonsils are inspected; for this purpose the use of a second tongue depressor to retract the anterior pillar is a great help, particularly if the tonsils are imbedded. The colour and size of the tonsils is observed, and the presence of any purulent material or cryptic contents is noted. Palpation will ascertain if they are tender, hard or soft, and if the finger presses firmly on the outer part of the anterior pillar in a backward direction, and if to push the tonsil out of its fossa, some idea may be formed as to how firmly it is attached to the pharyngeal wall. Then, with a bent sterile probe, the condition of the crypts and their contents is investigated, and after a little tincture of iodine has been dabbed on the tonsil. Similar observations can readily be made on the lingual tonsil with a laryngeal mirror. Finally, the condition of the submaxillary and inferior parotid groups of cervical glands is examined, and only then can an opinion be given.

Indications for Tonsillectomy.

If the tonsillar tissue is merely hyperplastic—that is, if no inflammation is present—and if it is not causing obstruction, then there is no indication for operation.

On the other hand, if there are definite signs of obstruction, but only in the nasopharynx, then the adenoids alone should be removed. Dyspnœa and ear symptoms referable to hyperplasia of the faucial tonsils will call for their extirpation. If examination suggests that infected adenoids are responsible for an ear suppuration, chronic rhinitis or sinusitis, pharyngitis or laryngitis, or, particularly, a retropharyngeal abscess, their removal is indicated. A definite history of peritonsillitis, or the presence of enlarged cervical glands not demonstrably due to another cause (teeth, malignant disease, syphilis, Hodgkin's disease, leukæmia, &c.), are clear indications for operation on the faucial tonsils, or, if the inferior parotid glands are involved, on the adenoids. If examination confirms that the faucial tonsils are responsible for recurrent sore-throats, repeated "colds" which always begin in the throat, frequent

rged glands, chronic rhinitis, inflammatory con-ons of the ears, pharynx, or larynx, or that they playing a part in a local degeneration such as sclerosis, then they should be excised. In systemic ase, if the tonsils show evidence of chronic (or ier continued) inflammation, in which the pillars he fauces may share, and are hyperæmic, tender, osed, or adherent to the wall of the pharynx, and a pure culture of streptococci is obtained from r crypts, and especially if they are associated n "glands," then they must be sacrificed.

Recommendations.

rom the fruit of a fairly extensive experience, ch has not been by any means an uninterrupted ch of infallibility, I offer three hints. First, ude neoplasms and blood dyscrasias before setting h to remove what appear to be "just ordinary ils." Secondly, if there is any tendency on the of the patient to bruise readily, have a blood gulation test done. Lastly, the possible presence of genital syphilis should be kept in mind when one sked to remove adenoids for "catarrh" or nasal rmity.

Clinical and Laboratory Notes.

TWO CASES OF ATYPICAL TETANUS.

S. T. IRWIN, M.CH. R.U.I., F.R.C.S. EDIN.,
SURGEON, ROYAL VICTORIA HOSPITAL, BELFAST.

HE reports of two cases of cephalic tetanus, one Drs. Fletcher and Fitzpatrick and one by Dr. Neil Simpson, in THE LANCET of Sept. 10th and respectively, afford me the opportunity of ing on record two examples of atypical tetanus h I saw some years ago.

SE 1.—A schoolboy, aged 18, consulted me on Oct. 16th, , on account of a small pustule on his right cheek.

story.—A fortnight previously he had cut himself shaving before playing football on a muddy ground. arly fall smeared his face thickly with mud and the d remained painful and did not heal. He had been from home, sitting for a scholarship examination, when he returned his mother noticed considerable ing and redness of the right cheek and right side s neck.

amination.—There was marked redness and swelling e right side of the neck filling up the space below the of the jaw and extending upwards in front of the ear. A small pustule was discharging just below the minence of the cheek and between this point and the angle of the mouth. The temperature was normal and ulse 100. There was no fluctuation, but the area was ny and tender, especially behind and below the angle e jaw. There was no spasticity of the muscles, but some in the lower jaw on the right side when the mouth opened.

this time there was no evidence of tetanus, and the n was thought to be a subacute lymphadenitis of the ds draining the cheek—the pre-auricular gland and those e neck below the angle of the jaw.

vo days later, as there was no material improvement fomenting, the boy was seen a second time. The ss and swelling had become more localised to the , but there was still redness and œdema of the whole side of the face as well. The boy was therefore sent to rsing home and an incision made in the centre of the en area over the point of maximum tenderness. No was found, and a prophylactic injection of antitetanic n of 1500 units was given subcutaneously. Next day swelling was considerably less. There was some pus arging from the incision and the wound in the cheek firmly healed.

ree days later the conditions in the neck had still er improved; there was only a slight discharge from incision and swelling was localised to this area alone. redness and œdema had vanished. The patient felt well except for some abdominal cramps which had ied him through the night, but which he had not erto mentioned. On pulling down the bedclothes I was fied to observe intermittent contractions of the recti cles of the abdomen. These were easily provoked by exposure, by light touch, and even by pretending to flick the skin in the boy's sight. The spasms were accompanied by shooting pain. On palpation the abdomen felt somewhat rigid, but not markedly so. With the onset of his spasms the abdomen became board-like. It seemed clear, therefore, that the condition was one of tetanus rendered abnormal by the injection of serum. It was hoped that the prophylactic injection of serum, added to the long incubation period, would justify a favourable prognosis. Prof. Thomas Sinclair kindly saw the boy with me the same day. He agreed with the diagnosis and the case was treated in accordance with the method described by Purves-Stewart—namely, 3000 units of antitetanus serum were given hypodermically, 3000 intravenously, and 1500 units intrathecally, after the withdrawal of a like amount of cerebro-spinal fluid. Next day 3000 units were given hypodermically and 3000 intravenously. For a week gradually diminishing doses of serum were continued until 30,000 units in all had been given.

The spasms ceased abruptly after the first series of injections, and the boy made an uninterrupted recovery. He has since gained considerable distinction, both in the examination room and on the athletic field, though a rather extreme degree of "nerviness" has been attributed, justifiably or not, to the use of the serum.

Cephalic Tetanus.

CASE 2.—On Friday, July 21st, 1922, I was asked to see a boy aged 5.

History.—On Monday, July 10th, he fell on his head from a wall five feet high in a farmyard. The right side of his forehead struck the ground and sustained a wound at the junction of the brow and scalp. The wound was about one and a half inches long and was situated about one inch from the middle line. He was somewhat dazed by the fall, but did not lose consciousness. The wound was dressed and sutured the same day. For two days and nights the boy was poorly, and on July 13th the stitches were removed and a fair amount of pus escaped. Next day the boy could not be induced to get out of bed, and even at this early stage his mother thought there was some asymmetry in his face. This asymmetry became more marked on the following days, and on the 21st—11 days after the fall—he could not swallow fluids and had some difficulty in separating his teeth. It was on this day that I saw him for the first time in consultation with his own doctor. I noted the following:—

1. A wound of the right frontal region about one inch from the middle line. This was apparently firmly healed and painless. 2. There was no sign of depression, irregularity, or tenderness in this neighbourhood. 3. The face as a whole was passive and mask-like. When the mouth was opened, the left angle was drawn outward and downward, the other parts of the face remaining immobile. The naso-labial fold on the right side was obliterated. 4. The child could not swallow. When he tried to take water there was a tonic spasm of all muscles of the face and neck, the water being expelled intermittently by a series of short expiratory explosions. He objected strongly to taking any kind of fluid into his mouth and seemed to be frightened when he was forced to do so. 5. There were no intermittent spasmodic contractions other than those produced by trying to swallow water. We watched him carefully for an hour without observing a single one, though his mother had seen them. 6. There was a tonic spasm in both sternomastoids, both splenii capitis, both recti abdominis, and the adductors of both thighs. This spasm was moderate in all muscles—e.g., his chin could with difficulty be brought down to his sternum, the thighs could be abducted, and the head could be laid on either shoulder. His masseters were somewhat more tightly contracted than the other muscles, but the tip of the tongue could be protruded and was not deflected. 7. The pupils were equal and dilated, and reacted rather sluggishly both to light and accommodation. The movements of the eyeballs were apparently normal. 8. The condition of the arms, chest, and abdomen, apart from the recti, was normal. The pulse was 120 and the temperature 98° F. The knee-jerks were somewhat exaggerated, Kernig's sign was absent, and tache cérébrale absent also. 9. The mental condition was quite clear. 10. The most marked feature was a striking right-sided facial paralysis which affected the whole of the right and upper part of the left side of the face. When he tried to close his eyes both globes moved upwards, but the lids themselves did not close. The only part of the face which could perform voluntary movements was the left lower quadrant. The mother told us that the whole face took part in the convulsions.

Having considered the other common causes of facial paralysis—depressed fracture of the skull, fissured fracture tearing the seventh nerve, hæmorrhage, meningitis, and abscess of the brain—we ultimately concluded that the case

was one of abnormal tetanus of the cephalic type. This view was corroborated by: (*a*) The distribution of the paralysis, affecting the side of the wound and the contiguous part of the opposite side of the face. (*b*) The mental condition of the child. (*c*) The fact that convulsions affected the apparently paralysed muscles. (*d*) The tonic contraction found in other muscles, such as the sternomastoids, recti abdominis, adductors, &c. (*e*) The condition of the pupils. (*f*) The so-called "hydrophobic" symptoms when fluids were taken into the mouth.

The boy was treated at once with all the antitetanic serum available in the village near which he lived, and next day by large doses by the various routes. In spite of this, however, more muscles became affected, and he died on the thirteenth day from the receipt of the scalp wound and the second day after I had seen him.

These atypical forms of tetanus have had an added importance in recent years owing to the prevalence of encephalitis lethargica. I have seen two patients with this disease in whom a localised painful contraction of a muscle group closely resembled that found in the early stage of a case of atypical tetanus. In the former, however, complete relaxation of muscle occurs between the spasms; the spasm cannot be provoked by slight stimuli as in tetanus; and even large doses of antitetanic serum have no controlling power upon their occurrence

A case of atypical tetanus has been recorded [2] in which an abdominal operation was actually performed, with a fatal result. In this case the violence of the spasms burst the wound on three separate occasions, and death was due to a low type of peritonitis after all convulsions had ceased for several days. It is reasonable, therefore, to assume that with a correct diagnosis the patient's life would have been spared.

There are many recorded examples of abnormal types of tetanus. As Simpson says, they are certainly rare in any one man's experience, but their recognition becomes daily of greater importance, since the increase in potency of antitetanic serum would seem to justify the hope that, even where the incubation period is short, lives will be saved by its prompt use. They will not, however, be saved unless they are diagnosed early.

RECOVERY OF STREPTOCOCCUS SCARLATINÆ FROM EXPERIMENTALLY INFECTED BOOKS.

BY A. R. BALMAIN, M.B., B.S. LOND., D.P.H. OXF.

(*A Report from the Southern Group Laboratory, Metropolitan Asylums Board.*)

THERE appears to be no certain information that scarlatinal infection is ever carried by books.[3] The whole of the information at present available on this subject rests on surmise, and administration in preventive medicine is handicapped by this lack of exact knowledge.

This investigation was an attempt to ascertain, under experimental conditions: (1) if the *Streptococcus scarlatinæ* would survive on books; and (2) the length of time this organism would live.

Whether infected books can give rise to fresh attacks of scarlet fever is a question which can only be determined by actual infection of human volunteers susceptible to the disease.

The basis of the following work rests on (1) the establishment of the *Streptococcus scarlatinæ* as the cause of the disease by the Dicks,[4] and its confirmation by other workers, and (2) the use of the intracutaneous test (Dick test) as a criterion of the specificity of the organisms used.

[2] S. T. Irwin: Brit. Jour. Surg., vol. ix., 308.
[3] McCartney, J. E.: THE LANCET, 1925, ii., 212.
[4] Dick, G. F., and Dick, Gladys H.: Jour. Amer. Med. Assoc., Oct. 6th, 1923, p. 1166.

Methods Used in this Investigation.

Two strains of streptococci were isolated from t throats of early cases of scarlet fever. The reactio of these strains were investigated and toxins prepar from them. The toxins (diluted 1 : 1000) were test on known positive and negative human controls the intracutaneous method (Dick test) and ga appropriate reactions.

Cultures of these organisms in blood broth w sprayed on to the pages of books in large and sm doses. The streptococci from these books w recovered and isolated daily, both by smearing pie of the infected pages over blood agar plates a dropping other pieces into tubes of blood broth. T heavily sprayed books were examined for 28 d and the lightly sprayed ones for 18 days.

(*a*) *Type of Book.*—The books used were: eig ordinary ruled unused exercise books, two exerc books with ink writing, two printed books with rou paper.

(*b*) *Preliminary Control Test.*—This was perform for all the books before inoculation by the meth described under (*d*). They all contained sporing bac allied to the *subtilis* group, and some books a fe staphylococci. No streptococci of any kind w found.

(*c*) *Method of Spraying.*—The books were spray with the whole blood broth cultures. The spray was of two kinds: (1) heavy spraying with a na atomiser so that every alternate page or selected pa were soaked (dried in three days); (2) light spray with a scent sprayer on every fourth page (dr same day). This corresponded to a good dro infection.

(*d*) *Method of Recovering Organisms.*—For the f 14 days the books were examined daily, then ev three days. A piece was cut out of an inoculated p of each book using sterile scissors and force Separate pieces of paper thus obtained w (1) smeared on blood agar plates, and (2) rolled and dropped into blood broth tubes. After 24 hou incubation the plates and tubes were exami microscopically for hæmolytic streptococci and wh necessary by further sub-culture.

(*e*) *Environment.*—The books were kept in gl jars under different environmental conditions as regards air, light, and temperature, but no differe in the time of recovery of the organisms was dem strated.

Results.

It was found that: (1) The number of streptococ colonies obtained on blood agar from the infec books diminished in number after six days (=sur infection), and no streptococci could be isolated by twelfth day from two of these books. (2) The num of streptococci discernible in stained smears from broth tubes diminished in 11 days. (3) With hea sprayed books recoverable streptococci were sca by the 18th day; not recoverable from one book the 26th day; only in very small numbers from other books on the 28th day. With lightly spra books streptococci were definitely present in sca numbers on the 18th day.

An attempt was made to determine the perio viability of *Streptococcus scarlatinæ* on books dire inoculated by droplet infection by two cases of sca fever. This experiment was not completed.

This investigation has thus shown that the *Strep coccus scarlatinæ* under experimental conditions survive on inoculated books and can be recovered f them during a period of four weeks. The numbe streptococci was scanty after the second week f the time of inoculation.

I am indebted to Dr. J. E. McCartney for encouragement and advice; to Dr. T. H. Woodf for placing cases at my disposal; and to the Me politan Asylums Board for permission to under research work in their laboratories.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

CRIMINAL LAW AND INSANITY.

LORD HEWART (Lord Chief Justice) delivered the th David Lloyd Roberts lecture on Nov. 16th at e Medical Society of London before a large and stinguished audience. The chair was occupied by r. HERBERT W. CARSON, President of the Society, ho reminded his hearers that the lecture was founded a former Fellow of that Society and was delivered rotation at the Royal College of Physicians of ndon, the Medical Society of London, and the Royal ciety of Medicine.

Medico-Legal Misunderstanding.

The medical profession and the legal profession em, said Lord HEWART, to have so much in common, d to be devoted in so unusual a degree to the public lfare, that any real misunderstanding between them on a matter of public importance would be much be deplored. Yet from time to time it is possible discern some indications, at any rate, of a lack of mplete harmony in the views with which the two ofessions respectively regard, or tend to regard, e attitude of the criminal law towards insanity. e true description of the subject matter of that ference, or apparent difference, is of no small portance. Accuracy in this point is essential, and k of it has sometimes led to mistakes. The ject matter is not insanity, but the attitude of the minal law towards insanity. It is natural enough, doubt, that the medical profession and the legal fession should regard and examine insanity from newhat different points of view. That circumstance, from being matter for regret, is matter for positive isfaction. What is to be regretted, if it exists, is lifference of view not upon insanity, but upon the ual and the proper attitude of the criminal law wards insanity. It is probably an underlying mis-ception of the precise nature of the subject matter t has led to a difference which is more apparent n real.

The Legal Principle.

The leading principle of the criminal law of England ating to insanity, Lord Hewart continued, is capable brief and clear statement. It is still to be found in answers given by the judges to the House of Lords McNaghten's case. The law is that every man is sumed to be sane and to possess a sufficient degree reason to make him responsible for his acts until contrary is proved to the satisfaction of the jury o are trying him. In other words, the burden of of where insanity is pleaded is upon the defence. s not for the prosecution to establish the sanity of accused; his sanity is presumed. It is for the used to prove, if he can, that at the material time was, within the meaning of the criminal law, insane. is to be observed that the word is "prove"; it is "suggest," nor "indicate," nor "insinuate," nor such word, but "prove." Nothing short of proof sufficient. In order to establish a defence on the und of insanity it must be clearly proved that at time of the committing of the act the person used was labouring under such a defect of reason m disease of the mind as that he did not know the ure and quality of the act he was doing; or if he know, that he did not know he was doing what was ng. The meaning of these words is sufficiently in. The crucial time is the time of the committing he act, and not some other time, either earlier or r. A sufficient defence of insanity relating to that e must satisfy three several conditions, the first of which are in every case obligatory, while as to third—contrary to an error which is by no means ommon—there is a choice of alternatives. It must proved, that is to say, first, that the accused was fering from disease of the mind; secondly, that in sequence of that disease he was labouring under a defect of reason; thirdly it must be proved that that defect of reason so brought about was of one of two particular kinds. It is here that the alternatives arise.

An Alternative Defence.

The defect of reason due to disease of the mind must be clearly proved to be such as either (1) to prevent him from knowing what he was doing, or (2) to prevent him from knowing that he was doing what was wrong. The defence is not required to prove that both condition (1) and condition (2) were fulfilled, but it must prove the fulfilment of one or other of them. This third requirement, with its two alternatives, may serve to illustrate the difference between the standpoint of the physician and the standpoint of the criminal law. For the purposes of a physician examining a person in order to ascertain whether he is insane, it may be enough to find that the patient is suffering from disease of the mind and is, in consequence, labouring under a defect of reason. When those two facts are established it may follow, naturally enough, that the patient needs medical care and attention. But when the question is the very different question whether a person is to be excused from responsibility for what appears to be his criminal act, the criminal law insists upon further investigation; disease of the mind, of itself, will not afford an excuse. Consequential defect of reason will not, of itself, afford an excuse. If excuse there is to be on the ground of insanity, it must be further established that the defect of reason was of a particular kind and exhibit particular characteristics; that is, at the material time it prevented the accused person from knowing what he was about, or, in the alternative, prevented him from knowing that he was doing what was wrong. A little reflection shows the importance and value of this third requirement. It satisfies at least two tests. In the first place, it seems to be manifestly in accordance with justice and good sense, as it is in accordance with the principles of the English Criminal Law that a man should be excused from criminal responsibility if, through mental disease, he is, at the time of his act, in such a state of unreason as not to know what he is doing. That, of course, is what is meant by not knowing the nature and quality of his act. It means, for example, that he thought he was peeling an apple when he was, in fact, cutting a throat. And a like observation may be made when a man is, through a like cause, in such a state of unreason that although he knows what he is about, he does not know that he is doing what is wrong. Such was the case of a middle-aged woman who strangled her mother-in-law, laid the dead body on the hearthrug, and brought in the neighbours to see how well she had done her work. "It was my duty to do it," she said, "and, you see, I have done my duty."

In the second place, this requirement of the criminal law has the effect of providing a useful test and criterion which the evidence in the case may well enable a jury to apply. In other words, what the prisoner has said, what the prisoner has done, and the surrounding circumstances very often yield material which helps the judge and the jury to perceive whether it is true to say that at the crucial time he did not know what he was doing, or did not know that he was doing what was wrong.

The Law does not Define Insanity.

Such, said Lord Hewart, is the leading principle of the English criminal law upon the matter. The law does not purport or presume to define insanity; that is a medical question. What the law considers is the conditions which have to be satisfied in order that a person may be excused from criminal responsibility. That is a legal question. And, at present at any rate, that question is answered, in this country, in accordance with the principles laid down in McNaghten's case. It is possible, no doubt, to find in text-books, and especially in footnotes, passages which seem to entertain, or to suggest, a broader—not to say a looser—view. It is even possible, perhaps, to find, here and

there, a similar passage in the report, whether accurate or not, of an individual summing-up in a capital case. But the law remains, and it is never to be forgotten that, as matters now stand, it is only the defendant who can appeal to the Court of Criminal Appeal. No such opportunity is open, in England, to the prosecution. Nor is it to be forgotten that while a physician tends to regard primarily the interests of his patient, the criminal law is concerned with the public security. "When I am invited," said Sir Matthew Hale, "to pity the criminal, I reflect also that there is a pity due to my country." That is not to say, of course, that criminal responsibility should be imputed where it does not really exist; but it does mean that criminal responsibility should not be overlooked in those to whom it properly belongs.

There is no reason why time should be consumed in the examination of the silly, the ignorant, or the captious criticisms which have from time to time been directed against the principle of the English law. The ancient philosopher, as everybody recollects, drew a distinction that remains eternally sound, between the kind of controversy called eristic, which seeks triumph, and the kind of controversy called dialectic, which seeks truth. No serious person in this matter has any concern with any argument or representation which does not seek to elicit and to establish what is true. Charlatanism and chicanery, for which, of course, there is a rich and attractive field, may be left severely alone. It would be idle, and worse than idle, to dwell upon their suggestions or to advertise their authors. On the other hand, every serious person is deeply concerned to examine every argument or representation which does aim at the truth, and to treat their authors with sincere respect, however acutely opinions may differ. The test was brought to a point five years ago when, after a certain notorious trial for murder, a committee was appointed, under a learned chairman of high distinction, to consider, among other things, any changes which might be desirable in the existing law relating to criminal trials where the plea of insanity is raised as a defence. The Council of the British Medical Association, among others, tendered evidence and submitted representations to the committee; the materials are fully set out in the extremely interesting and valuable report of the committee, dated November, 1923, and presented to Parliament in 1924. It seems accurate to say that the Association, in substance, approved the rules in McNaghten's case, but added the qualification that no act should be regarded as a crime if at the time when it is done the person who does it is prevented by defective mental power or by any disease affecting the mind from controlling his own conduct, unless the absence of the power of control is the direct and immediate consequence of his own default. The committee so far agreed with the report of the Association as to recommend, first, that it should be recognised that a person charged criminally with an offence is not responsible for his act when the act is committed under an impulse which the prisoner was, by mental disease, in substance deprived of any power to resist. And, secondly, that in other respects the rules in McNaghten's case should be maintained.

Suggested Modification of the McNaghten Rule.

It is important to see clearly the effect which this modification, if it were adopted, would produce upon the existing rule. Is it not manifestly an alteration, and a fundamental alteration, in what has been described as the third requirement or condition? In other words, if the suggested modification were accepted it would be immaterial that the prisoner knew what he was about, or that he knew he was doing what was wrong. He might, indeed, be well aware of the one and the other; but he would still be excused from criminal responsibility if he committed the act under an impulse which he was, by mental disease, in substance deprived of any power to resist.

This suggestion, whatever its merits may be, is not at all a product of the twentieth century; it is really, if the phrase may be employed without disrespect, the ancient and dangerous plea of the uncontrollable impulse, which, in practice, is so difficult to distinguish from the impulse that is not in fact controlled. The doctrine, it will be seen at once, involves two propositions which are by no means of the same kind, nor indeed upon the same plane. The first proposition is a proposition of fact—namely, that there are as a matter not of scientific imagination nor of controversial speculation, but of actual experience, unfortunate persons in existence who, though they know what they are about and also know that they are doing wrong, are nevertheless impelled by diseased and irresistible impulse to commit an apparently criminal act.

The second proposition is a proposition of legislative morality or expediency—namely, that these persons by reason of their number or otherwise, are of such importance as to require or deserve a fundamental revision of the criminal law. It seems to be highly necessary to observe the distinction and the real difference between the two propositions.

The Plea of Uncontrollable Impulse.

As to the first of them, a mere lawyer would, of course, hesitate much before he ventured to express an opinion. It appears evidently to become a proposition of a kind which belongs rather to the field of medical observation and experience, not, of course, provoked by questions asked in a particular cross-examination but derived from special opportunities of general study in an extremely difficult branch of scientific inquiry and research. Let it be granted, therefore, for the sake of the argument—and for the sake of the argument alone—that persons of this unfortunate type do in fact exist; the question remains whether for that reason, it is just and necessary to enterta or to make a drastic alteration in the criminal law. A moment's reflection will show how widely the do would be thrown open if the alteration were mad The objective tests for judge and jury wou immediately and finally disappear. It would be little use to explore the evidence in order to ascerta whether in the particular case the prisoner w perfectly well aware of what he was doing, or perfect well aware that he was doing what was wrong. T crucial, the overriding, the dominant question wou forthwith come to be whether he was acting under irresistible impulse. And upon what materials a with what guidance would the jury be called upon answer that question? Would there be any materia or guidance at all, except the medical opinion, whi the prisoner might be fortunate enough to be able adduce in his favour, contradicted by the medic opinion which might be offered on the part of t prosecution?

It seems natural to ask what are the true dimensio of the difficulty for which so far-reaching a solution suggested. Upon this important question the repo of the committee already referred to may be thoug to be illuminating. "It was established," the repo says, "to our satisfaction that there are cases f mental disorder where the impulse to do a crimi act recurs with increasing force until it is, in fa uncontrollable. Those cases of mothers who have be seized with the impulse to cut the throats of, otherwise destroy, their children, to whom they a normally devoted, are not uncommon."

To pause there for a moment, it is interesting to n that the illustration which is selected is the case f a mother killing her child. But already a spec statute which deals with infanticide offers a leni alternative in cases of mental disturbance falling short of insanity, where a mother not yet fu recovered from the effects of childbirth destroys newly born child.

"Guilty but Insane."

To return, however, to the report of the committ the very next sentence after the two sentences j quoted is in these words: "In practice in such ca the accused is found to be 'guilty but insane.'" I not that a very remarkable statement? It seems so say, in the clearest possible language, that what is

quired is already done. If the proposed change in e law were made the verdict in such cases would be e verdict which is briefly, popularly, and inaccurately scribed as "guilty but insane." But this verdict, it pears, is, in practice, already returned in such cases. What, therefore, remains? "We appreciate," the mmittee frankly add, "the difficulty of distinguish- some of such cases from cases where there is no ntal disease, such as criminal acts of violence, or ual offences, where the impulse at the time is ually not merely uncontrolled, but uncontrollable." d yet a far-reaching change in the law is recom- nded apparently upon the ground (to quote the act words) "that the McNaghten formula is not ically sufficient." Now, even if the hypothesis eady set out be accepted as true, it may be thought at lawyers and statesmen will hesitate long before y open the door to a quite incalculable flood of schief for the purely academic purpose of giving ical sufficiency to a formula, or a superior degree correctness to verdicts which, in practice, are eady returned. But, indeed, the doctrine or theory the uncontrollable or irresistible impulse is not in smallest degree novel. It is, without doubt, older n the McNaghten case itself, and therefore may be en as having been considered and rejected by the rned judges who answered the questions in that e. In the year 1859—that is, 16 years after the Naghten case—the matter was referred to by a at judge in a well-known case. "If an influence," l Baron Bramwell in R. *v.* Haynes, "If an uence be so powerful as to be termed irresistible, much the more reason is there why we should not hdraw any of the safeguards tending to counteract There are three powerful restraints existing, all ding to the assistance of the person who is suffering ler such an influence—the restraint of religion, of science, and of law." But if the influence itself is be held a legal excuse, rendering the crime dis- ishable, you at once withdraw a most powerful raint, that forbidding and punishing its perpetra- n. Four years later—in 1863—Mr. Justice Wightman, R. *v.* Burton, referred to the doctrine of the ontrollable impulse as a most dangerous doctrine, al to the interests of society and the security of life.

The Security of the Public.

As to the suggestion, which is more often implied n expressed, that under the law, as it now stands, ne prisoners are wrongly held to be fully responsible, nay be doubted whether any lawyer knows of any h case. The tendency is the other way—that is, to ept the defence of insanity, especially in a case ch for any reason excites sympathy, upon materials ch are too slender. This course is, no doubt, regarded umane to the prisoner. But perhaps it pays too e attention to the misery of prolonged confinement what is called a criminal lunatic asylum. For the urity of the public, on the other hand, can there any real doubt that the comparative stringency of existing law is necessary? After all, the mere that a man thinks he is John the Baptist does not tle him to shoot his mother. And if a man of ormally jealous disposition entertains suspicions as he chastity of his wife and his suspicions become t it is fashionable to call an obsession and finally xed delusion, is he with impunity to kill her by soning, having done all he could to conceal the ne?

seems true to say that in cases where there is lence of real mental disease antecedent to the mission of the alleged crime, and there is no lence of a motive which might influence a sane on, juries have no difficulty in finding either that prisoner did not appreciate the nature of his act hat he did not know it was wrong.

ut if, Lord Hewart concluded, the law were xed in the way which has been suggested, it might be that in cases where there has been no such lence of mental disease antecedent to the alleged ne, mental experts would be found to say that the ged crime itself afforded evidence that it was mitted under an uncontrollable impulse, and that upon that ground the inference might be based that there was mental disease. If so, the result might be to transfer to a section of the medical profession the question whether a great number of ordinary criminals should be held responsible to the law.

ROYAL SOCIETY OF MEDICINE.

A COMBINED meeting of the Sections of Electro Therapeutics, Medicine, Surgery, and Orthopædics was held on Nov. 17th, Sir HENRY GAUVAIN, President of the Section of Electro-Therapeutics, in the chair. The subject of discussion was

RADIOLOGICAL PITFALLS.

Dr. A. E. BARCLAY (Manchester) said that radiology could only show the gross outline and the density of the substances which the rays traversed. However vital the X ray evidence might be, the radiologist should not use the word diagnosis.

For present purposes he regarded a pitfall as no more than an appearance which gave rise to a blunder—the blunder being self-evident as soon as the interpretation was known. Unless there was real urgency it was desirable to carry out a definite routine and to study a radiograph quietly. This routine might sometimes appear to cause delay, but it would obviate many mistakes which were due to haste. If the radiologist knew beforehand what diagnosis had been reached clinically this knowledge must prejudice his own decision; but he should be supplied with all the vital points in the history of the case, so that he could make his examination on the right lines. There was always a tendency to look for the things which one expected to find, and the physician's diagnosis was very liable to be biased by the radiographic findings. The danger of prejudice was so great that it was of doubtful benefit to the patient if the clinician did his own radiology. The best plan was for the radiologist and the physician to come to their conclusions independently and then to discuss the case together afterwards. The tendency at present was to put too much responsibility on the radiologist.

It was obvious that unless films were of good quality their inferiority was in itself a real pitfall; another cause of error was dark-room carelessness. Dr. Barclay showed a number of skiagrams illustrating his argument. In early lesions of bone, he said, such as those of osteomyelitis, it should be remembered that the changes took time, and at an early stage the radiogram might give either no indication or a wrong interpretation. In conclusion he declared that most pitfalls could be avoided if the radiologist kept his mind alert not only radiologically but also medically, and seldom departed from a well-ordered routine.

Dr. E. I. SPRIGGS (Ruthin) spoke of the danger of allowing a radiological or other special examination to be a substitute for a study of early history and clinical symptoms. The radiologist shared with the surgeon and morbid anatomist the capacity to find something; the question was, had the something anything to do with the illness of the patient? A finding could not be regarded as a diagnosis. "Dropped stomach" or "dropped colon" was not a diagnosis; such a condition resulted from something outside the viscus, and to cure the viscus would not necessarily cure the patient. The second great cause of mistakes was a lack of coöperation between the radiologist and the physician. The radiologist should be told something of the general clinical character of the case. A third class of pitfall was that due to a partial or imperfect examination. Certainly many errors could be avoided by taking oblique skiagrams. A fixed technique meant incomplete examination, and no means which could yield information should be neglected. Dr. Spriggs also demonstrated a series of skiagrams.

Mr. MAX PAGE gave consideration to mistakes in the diagnosis of fractures and in the recognition of malignant bone disease. He had seen a number of gross errors in both these categories and had considerable sympathy with those clinicians who said that

nowadays the radiologist was allowed to take much too important a part in diagnosis. This was especially true in the matter of teaching. Radiology was a physical method which one should make use of as an addition to the information conveyed by the senses, but not as a substitute for it. The omission to take two radiographic views of a case sometimes resulted in foolish mistakes. Stereoscopic views should also be available. Not long ago even competent radiologists failed to provide the surgeon with a lateral view of the spinal column which was of any value in the interpretation of the bone condition. He demonstrated by a series of skiagrams the kinds of mistake caused by misinterpretation of X ray findings. Odd and unusual ossicle formations sometimes caused much hesitation —e.g., in connexion with sesamoid bones—whilst extra ossicles on the patella gave the impression of loose cartilage in the knee. These cases laid definite traps. He had been struck by the futility of relying on radiological plates to diagnose early tumours of bone. In cases of central cyst, or central tumour, or central abscess of bone, the diagnosis must not be attempted by radiology, for a number of serious cases would be missed by waiting for positive radiographic findings. Radiograms would not show whether a condition was simple or malignant; the early development of periosteal sarcoma was not shown by the ordinary radiogram.

Mr. H. A. T. FAIRBANK said that two not uncommon causes of inaccurate diagnosis were ignorance of the normal anatomy, as seen on the X ray plate, and forming conclusions on a case when the film was imperfect. He did not know of any more difficult cases to diagnose than those presenting a suspicion of caries of the spine. In such instances he refused to give an opinion without being supplied with good stereoscopic and antero-posterior films. Several cases of supposed caries were found to owe the spinal deformity to a developmental error. Sarcoma of the spine, perhaps associated with paraplegia, might cause a good deal of diagnostic difficulty. It was difficult to be sure, from the skiagram, of an early stage of adolescent coxa vara. When the displacement was slight a lesion of the epiphyseal line was often overlooked, especially if the film was not very clear. The two femora should always be compared.

Dr. A. F. HURST said that the earliest radiological sign of a growth in the stomach was a fading away of peristalsis as the wave passed along the greater or lesser curvature, a sign which an X ray plate did not reveal. Gastric ulcer near the cardia should only be diagnosed after careful consideration, as most of the abnormalities in that situation were not ulcers, but congenital gastric diverticula. Stasis alone—even a 12-hour stasis—should not be deemed a sufficient reason for diagnosing pyloric obstruction; to justify such an opinion there should also be exaggerated peristalsis. Quite 95 per cent. of cases of pyloric obstruction which were not caused by a new growth were due to duodenal rather than gastric ulcer. A pre-pyloric ulcer was very rare. In pyloric obstruction the stomach was nearly always full of gastric juice when the patient presented himself fasting in the morning. The stomach should be emptied by means of the stomach-tube, after which a meal should be given. The pyloric end of the stomach could then be seen and barium could be seen passing through the narrow pylorus and the irregular duodenum, and the duodenal obstruction was displayed. In such a patient duodenal deformity did not mean that duodenal ulcer was active; it was seen in all types, perhaps 20 years after an ulcer had healed, whether as a result of gastro-jejunostomy or of medical treatment. An ulcer should only be considered active when clinical or laboratory signs showed that it was so. Adhesion at the right iliac fossa was a favourite diagnosis when pain occurred in that region after the appendix had been removed. But this conclusion should not be drawn, whether the patient's appendix had been removed or not, without carrying out the very important test of inflating the rectum and pelvic colon with air. This would unravel the terminal ileum. Another error arose from diagnosing ile stasis, a condition which hardly ever existed; whil still another mistake was to conclude that the findi of a stomach low down meant gastroptosis. Som times the condition was simply a congenitally lo stomach. The same remark applied to ptosis of t transverse colon. In 50 per cent. of young girls t cæcum was erect. Mistakes could also be ma concerning the tone of abdominal viscera. At o time he had thought that duodenal ulcer was nece sarily associated with a hypertonic stomach, b investigation had now shown him that the tone these cases was not abnormal. The tone was sho by the upper level of the gastric contents.

Dr. A. C. JORDAN showed skiagrams illustrati intestinal conditions. Errors could often be avoide he said, by never omitting a barium enema, as th showed kinks in the pelvic colon which the bismu meal did not reveal, as it did not fill the late portions of the large intestine.

Dr. H. WARREN CROWE (Harrogate), speaking radiography of the teeth, said that this could nev prove that a tooth was healthy, however perfect might appear. On the other hand, a radiogram ma it possible to say that a tooth was infected. It w a mistake to suppose that because the bone round tooth was fibrous, dense, or sclerosed, therefore th tooth was not as dangerous as one which had an apic granuloma by its side. As a matter of fact the presen of such dense bone round a tooth indicated a great danger of the system becoming infected than did apical granuloma. The last pitfall he mentioned w that of concluding, because the teeth were very ba that any systemic disease the patient had was nec sarily caused by their presence.

Dr. F. HERNAMAN-JOHNSON emphasised a rema made by Dr. Jordan, that when an abdominal lur disappeared after an enema had been given it w dangerous to assume that it had been merely collection of fæces; it might be the first evidence f carcinoma, which had set up a functional paraly which was the direct cause of the fæcal accumulatio Mistakes might arise when dealing with an accide or emergency in a patient's house. In one such ca following a motor accident a neurologist had been su that the trouble was at the eleventh and twelfth dor vertebræ. The patient was in great pain and it w difficult to get the plates for the skiagram in positio Dr. Hernaman-Johnson had got a plate as far as t second lumbar and was told there was no need f anything further. The symptoms were put down shock. The patient did not get well, however, and months later he skiagraphed the whole spine and fou a very distinct fracture of the third lumbar spine, wh had been missed in the previous examinations. T moral of this case was to decline to accept what oth said about a case and to investigate at least five six vertebræ around the site of the alleged injury. was quite sure ileal stasis existed as he had seen a ca of it. He also thought, in spite of what Dr. Hurst sa that now and then actual ulcers occurred towards te cardia, though they might be missed unless the patie was first examined in the horizontal and then in t vertical position, to allow the opaque meal to fill the cavity.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

A MEETING of this Society was held on Nov. 18, when Dr. E. H. SNELL (M.O.H., Coventry) to the chair in the absence of the President, Dr. WHEATLEY. Dr. JOHN BUCHAN (M.O.H., Bradfo opened a discussion on

HEALTH ASPECTS OF THE FACTORIES BILL.

He said that factory legislation, which had had a gr influence for good on the people of England, be 125 years ago, thus preceding by many years legislat dealing with health and education. The Factory A were administered by a department in Whitehall wh

l little other relationship with either health or ıcation. The present Factories Bill was a consoli- ing measure; it marked but few fresh develop- nts in such legislation, and Dr. Buchan found it ficult to see why it was supposed again to stand need of such consolidation, this being the third empt since 1878. His criticism, he said, would bear n some of the minor points of the Bill. It used one m to denote both factories and workshops, but definition raised administrative difficulties. The ct of the change would be to lay the responsibility the administration of workshops on the Factories partment of the Home Office, and he thought this s unlikely to mean increased efficiency or economy. e last report of the Factories Department showed t in 145,000 factories the factory inspectors dealt h 19,000 cases of sanitation, whereas in 128,000 istered workshops the district councils dealt with r 40,000 matters of sanitation and cleanliness. It s provided that the Home Secretary could delegate ıe of the duties, but he was not paramount, and rict councils, as a whole, could not be said to have great love for duties which he had delegated to m. If those councils were required to do the work hould be part of the Bill and come as a decision of liament. He had wondered what had occurred he last 50 years to cause the Government to revert he position before 1878, but he found that the tories Department, in dealing with sanitation, often rted what difficulties they encountered in getting ective sanitary accommodation rectified. But the retary of State could not delegate to councils the ting of workshops. To make this new Act a kable one, much was left to the common sense of medical officers of health, and Dr. Buchan believed se officers would do their best to make it a success, he regarded it as a badly drafted measure. The ers to act in default of the district council (vide ıses 10 and 11) could not be put into operation. art of the new Bill which he approved was that ch took power to order a medical examination of loyees in particular circumstances. A very good ance was the common one in which dusty occupa- ıs were liable to set up pulmonary tuberculosis. hoped it would be a very effective provision. It st be carried out in consultation with the Ministry Health. As it was presented in the Bill, however, as somewhat weak, as medical supervision could efused by a workman, and what was allowed to be e in this respect was what the employer might sider reasonable. This would probably prove to different from what the Home Office and the istry of Health deemed reasonable.

he clause concerning the lifting of weights in a ory by women and young people was well ntioned, but naturally the weight which could be fortably lifted would vary with the individual, and clause was in the control of factory inspectors, would probably be slow to pass such opinions as framers of the Bill had in mind. Clause 53 dealt h basement bakehouses, and in the new definition age rooms were not regarded as part of the ehouse. The definition, which Dr. Buchan sidered defective, read: "Any place in which are ed bread, biscuits, or confectionery from the ing or serving of which profit is derived." Dr. han considered that the clause dealing with the ification by the doctor of young persons as fit for articular employment was a definite advance. sically defective children could be prevented from ring factories, but he thought that some further vision was needed dealing with the after-care of such dren; the factory question was for them not the one, nor the most important. It illustrated very the undesirability of dealing with factory services pendently from other health functions. Certainly ould not be the province of the factory inspector ay that a particular child should not be allowed to k in a factory.

ieut.-Colonel F. E. FREMANTLE, M.P., did not agree t the Bill brought in only minor changes. But at me when industry was hard put to it to make ends meet it was scarcely to be wondered at that employers were somewhat afraid of further legislation. This went to the root of the difference between the Home Secretary, who was determined to get this Bill through if he could, and the employers of labour, who were doing what they could to prevent it. Certain points in the new Bill closely affected the health of the worker. The alterations in regard to welfare provisions were negligible, but two important omissions concerned the means at the disposal of employees for washing and for drying their clothing. It was the boys who required protection against weight-lifting, as they liked to emulate men in feats of strength. Women and girls could usually be trusted not to go beyond their comfortable capacity. With regard to hours worked, the only restrictions in this Bill concerned women and young persons of 14 to 18 years of age. The hours they worked must not exceed ten a day, or 40 a week, or not more than 12 hours must be spent daily in the factory, including meal times. Some factories allowed a ten-hour day for five days, to permit a long week-end, but Colonel Fremantle thought that nine hours should be the limit. At present, except under special circumstances, overtime for young persons was illegal, but this measure now made that permissible. The Home Secretary might, for seasonal trades or exceptional pressure, allow young persons to work 50 hours a week, but on no day must the hours exceed 11, or with meal times 12 hours daily. He thought that overtime should not bring the weekly hours worked for young persons beyond 48. Where sanitary measures were concerned he thought powers should be given to the Home Secretary only after consultation with the Ministry of Health. A provision about such consultation should be inserted in the Statute. He thought the term "medical officer" should supplant that of "doctor," as the meaning of the latter was teacher. Many workshop proprietors already appointed medical officers for purposes of their own and for the welfare of their employees; and when such a medical man could undertake the general medical duties of the factory, he got to know the people in such a way that he was best qualified to maintain the health of the workers and prevent sickness. He doubted whether the average school medical officer would be suitable for factory work, which should be a complicated piece of clinical work. A factory surgeon could not well certify people as fit or not fit without knowing a good deal about the work in question. What was required, he thought, was an inspection as intimate in the factories as into ordinary works of sanitation, and he was doubtful how far this Bill would carry that out. The Secretary of State and his Department must be helped by constant consultation with the Ministry of Health.

Dr. A. H. BYGOTT (M.O.H., West Suffolk) described the Bill as a departmental measure, and did not see why the work of the whole office should not be taken over by the Ministry of Health; it was one of the purposes for which that Ministry was constituted. He regarded the Home Office as a moribund institution. He objected to so little a cubic space provision per worker as 250 cubic feet; at least 400 cubic feet should be allowed. Heating and the drying of clothing should be included in the Bill, and no overtime should be worked by young people, except in the case of breakdowns and other matters of emergency. He did not think the ordinary medical practitioner, with no knowledge of factories and no qualification in public health, should be appointed to deal with factories officially.

Dr. CYRIL BANKS (M.O.H., Halifax) thought it would be a pity if the local authorities were deprived of the powers they now possessed for supervising the conditions under which people worked; they had a good deal of influence with mill-owners in getting them to do necessary things. Factory inspectors were not by any means always reasonable in their demands.

Dr. STELLA CHURCHILL (London County Council) doubted whether the present number of factory inspectors was adequate, and thought that the conditions of work for young people in offices should be

included in the Bill. No person under 18 years of age should be allowed to work as many as 48 hours a week. Was there anything in the Bill to stop dwelling-houses being used for factories? If employers appointed their own medical officers she thought that the latter would not feel free to say what they thought.

The CHAIRMAN said he lived in a town which bristled with factories, and yet all they had was one-tenth of one factory surgeon devoted to those factories. What could he do in that time? It was a mere side-show. Medical officers were wanted inside factories and workshops to study the conditions of work, in connexion with both employees and employed.

Dr. BUCHAN briefly replied.

ROYAL SOCIETY OF ARTS.

AT a meeting of this Society on the evening of Wednesday, Nov. 16th, at which Lord DAWSON OF PENN occupied the chair, Dr. LEONARD HILL, F.R.S., delivered an address entitled

Overcrowding in Public Conveyances.

Governed by traditional fear of catching cold, he said, travellers demanded closed and heated cars, and shunned the invigorating blow and exposure to sunlight that they should have to keep them in health. Man was naturally resistant to cold, and had very little trouble in adapting himself to it; when he did so he was free from infection and dust, and enjoyed the stimulation of his heat-producing mechanism and of his whole system. The magical effects of open-air schools on weakly children were well known. Wind blowing on the face put the mucous membrane of the nose and throat in the best condition for resisting infection, but a cold floor and warm stagnant air caused it to swell and become congested and covered with thick secretion; it was then vulnerable to infection. Persons whose membranes were habitually in this state bred germs and enhanced their virulence. Since the body's defence against infection depended largely on the rate of evaporation from the membranes of the nose, throat, bronchi, and conjunctivæ, a supply of cool fresh air was very important. The more the heat loss from these surfaces, the greater the compensating flow of blood, and the greater the secretion of cleansing lymph. This loss might be four times as much out of doors as indoors. Prof. Hill had introduced a "kata-thermometer" to measure the rate of cooling from body temperature in a given atmosphere, and had measured with it the hygienic conditions in various public conveyances. In a fresh, warm room the cooling power was about 6 dry-bulb and 18 wet; in a stuffy room, 4 and 14 respectively. In a cool, fresh room, like a sanatorium ward, the readings might be 10 and 25. Out of doors the dry "kata" gave a figure of about 10 on a summer day, 20 in a cool breeze, and 40 in a cold winter wind. A cooling-power of 14 dry was required to increase the heat production of the body when resting in ordinary clothing. The cooling power of the atmosphere of a compartment in a steam train varied, according to season, position of passenger, and aperture of windows, from 5 to 18½. Inside a bus in October it might be 9, in a tram in August it might be as low as 4, and the reading in a North London electric train was 4 in August, and 7 in October. Tube trains showed a cooling power of 5–8 in August, and 7–16 in October. The ventilation of trains should be improved by the fitting of exhaust fans, to run when the train was stationary, and the heating should be applied to the floor itself and reduced in intensity. Fog was responsible for overcrowding, delay, and faulty ventilation alike, all of which made for ill-health. Some of the crowding in trains might be reduced by abolishing classes. The danger to health in crowded vehicles was not in chemical pollution, which was obvious and distressing, but in the sharp rise in the degree of bacterial pollution. The organisms might be those of catarrh only, or of any of the exanthemata, of diphtheria or tuberculosis, poliomyelitis, or encephalitis lethargica.

Air Pollution in Tubes.

Dr. GRAHAM FORBES gave a summary of the results of an investigation conducted by him in 1920 on the air of the tube railways. 20 per cent. of the organisms belonged to varieties which grew in the throat. Tube air did not greatly encourage the development of organisms which grew at room temperature; the pollution ratio with the outside air was between 11·7 and 15·7 to ten. It contained, however, from 2½ to 5½ times as many of the organisms which grow at body temperature—the more important class for public health. These figures included the old Southern London railway. The bacterial content increased rapidly with the passenger rate, but the increase stopped at a certain point of overcrowding, possibly because of the resulting stagnation of the air. Humidity was a factor very favourable to bacterial survival. Chemical investigations, not yet published, showed that the carbon dioxide content was slightly higher than the 1902 standard, and that an excess of this gas was associated with humidity and bacterial pollution. The chemical pollution in the tubes had been found greater than in most public vehicles above ground, but less than in some places of entertainment.

Lord DAWSON entered a plea for older people, who were less able than young ones to stand fresh air in large quantities when they were fatigued.

Mr. FRANK PICK, general manager of the London General Omnibus Company, said that as long as passengers had been left to provide their own ventilation there had been constant disputes; buses were now fitted with an unclosable set of louvres behind the driver's seat, and the side windows could be opened if necessary. In compensation for the covering in of the tops, sliding windows had been fitted which allowed a good draught; these were also being fitted to the insides of buses.

MANCHESTER MEDICAL SOCIETY.

AT a meeting of this Society held on Nov. 2nd, Dr. J. GRAY CLEGG, the President, took the chair, and Dr. N. KLETZ and Mr. A. H. BURGESS opened a discussion on

Chronic Gastric and Duodenal Ulcer.

Dr. KLETZ said that the one ætiological factor which seemed to be approved by experience was infection—i.e., by septic material carried from foci of latent infection and primary emboli in end-arteries of the stomach or duodenum. It was important to go on seeking for the causes, since in the absence of such knowledge both medical and surgical treatment were liable to fail, because the cause remained operative and was consequently liable to reproduce the lesion. Clinical diagnosis both of gastric and duodenal ulcer was difficult. Diagnosis meant not merely recognition of the presence of an ulcer but also of its size, extent, locality, and relation to surrounding points and, if possible, of its chronicity. Pain was the chief symptom, and its regular rhythmical occurrence was regarded as indicative of ulcer and even, according to the type of rhythm as showing the position of the ulcer, whether gastric or duodenal. These deductions were unwarranted. Gastric pain—i.e., pure visceral pain—was either "delayed" or "immediate." It arose not in the ulcer itself, but as a result of hypertonus or abnormal tension of the gastric musculature. Either type of pain might be associated with ulcer but could equally well be evoked by stimuli from distant organs, such as the gall-bladder and appendix, acting on the stomach through reflex nervous mechanisms. Fullness might have the same significance as pain, and the absence of pain did not prove that no organic gastric or duodenal lesion was present. Somatic signs, when definitely localised and clear-cut, were of great

lue. Dr. Kletz drew attention to the importance complete investigation by radiography, fractional stric analysis, and examination of stools for occult ood. Each of these must be correlated with a reful clinical history and a thorough physical amination. Treatment was by no means neces-rily surgical. The first step should always be to ek for any focus of infection and it was especially nportant to examine the accessory nasal sinuses d teeth by X rays. Operative treatment should ways be undertaken: (1) where there was any ganic obstruction or hour-glass deformity;) where there was relapse after adequate medical eatment; (3) in cases of penetrating ulcer; (4) in ses of recurrent hæmorrhage; (5) when the ulcers re extremely chronic and indurated; and (6) in favourable economic or social conditions. Other ses should be treated medically. Failure to reduce idity might follow gastro-enterostomy and lead to currence of symptoms or even to jejunal ulcer, d adequate dietetic and medical control was sential after operation.

Mr. A. H. BURGESS said that from the published ures duodenal ulcer appeared to be much mmoner than gastric ulcer in the North of ngland, whereas in London gastric ulcer was more mmon than duodenal. Coincidence of gastric and odenal ulcer was frequent. D. P. D. Wilkie,[1] in analysis of 300 operations, had found that in per cent. of all duodenal ulcers there was a gastric er, and that in 53 per cent. of patients with stric ulcer one or more duodenal ulcers were sent. Rosenow had isolated streptococci from teeth and tonsils of patients with peptic ulcers, d also from ulcers removed by operation, and by ravenous injection of these streptococci into imals had produced ulcers in their stomachs ilar to those in man. From these ulcers strepto-ci had again been isolated, and had produced ilar ulcers on intravenous reinjection. These earches, said Mr. Burgess, emphasised the import-ce of a careful search for any focus of infection in teeth, tonsils, nasal sinuses, or elsewhere before eration, and in the appendix and gall-bladder ring operations. He considered that the super-ation of carcinoma upon gastric ulcer did not occur more than from 5 to 10 per cent. of cases. The onic ulcer arose as an acute ulcer or erosion; st erosions of this kind healed under medical atment and only a small proportion become onic. Medical treatment should therefore be opted in the early stages, and surgical treatment ould be considered only when it failed to relieve symptoms, or when they repeatedly recurred. mplications such as hæmorrhage, obstruction, and acute or chronic perforation, were indications for gery, and operation should be seriously con-sered where radiological examination showed a finite ulcer crater or marked deformity of the mach or of the duodenal cap.

Gastro-enterostomy for chronic ulcer of the stomach d first been performed by Doyen in 1892, and for odenal ulcer by Codivalla in 1893, and for many rs it had been the only operation employed in se cases. It had soon become apparent that its sults, both immediate and remote, were much tter in duodenal than in gastric ulcer. Excision the gastric ulcer with gastro-enterostomy had been d, but was soon abandoned, since recurring ulcer l even perforation sometimes followed. It had w come to be recognised that so far as the surgical atment of gastric ulcer was concerned there were essentials: (1) removal of the ulcer itself, ner by excision or by the cautery (Balfour); and the performance of gastro-enterostomy, or at any e, of some other operation by which the bile and ncreatic juice was allowed to enter the stomach ely and so diminish the tendency to hyper-dity. If hyperacidity persisted after gastro-erostomy then a secondary (anastomotic) ulcer was more likely to follow. The two essential procedures could be carried out either separately, as when excision or cautery-destruction was combined with gastro-enterostomy, or could be combined in the single operation of partial gastrectomy, often technically easier. The objection to partial gastrectomy was that it involved the sacrifice of a large amount of healthy stomach, often many times greater than the actual ulcer; though usually this did not appear to cause any ill-effect, yet several cases of pernicious anæmia had been reported following partial gastrectomy. The most difficult cases were those in which the ulcer was on the lesser curvature, high up, near the cardiac orifice. In such a case the partial gastrectomy would involve the loss of almost the whole stomach and local excision combined with gastro-enterostomy, if at all possible, was a better operation. Jejunostomy had sometimes to be performed in these cases, absolute rest being given to the stomach for many months, but relapses might occur when oral feeding was recommenced. L. R. Braithwaite [2] advocated in such cases the operation of cholecystogastrostomy ("gastric bilification") which had previously been suggested by Babcock.

In duodenal ulcer gastro-enterostomy gave good results in from 85 to 90 per cent. of cases, and combined with the removal of the ulcer by excision or cautery, appeared to be the procedure of choice. The "fly in the ointment" was the occasional supervention of jejunal or gastro-jejunal (anastomotic) ulcer. The estimated frequency of this unfortunate complication varied according to different writers. Balfour found that it occurred in 1·6 per cent. of gastro-enterostomies performed at the Mayo Clinic, whilst Lewisohn, of Mount Sinai Hospital, New York, found that 34 per cent. of 68 cases re-examined four to nine years after gastro-enterostomy showed gastro-jejunal ulcer. To avoid this complication surgeons had worked along two lines; some confined themselves to operations on the pyloric region, such as pyloroplasty and its many modifications, Finney's operation, or gastro-duodenostomy, whilst others radically excised a segment of the duodenum, sometimes combining this with extensive resection of the pyloric portion of the stomach (Pannett, von Haberer, Finsterer). One of the main objects of extensive resection was to produce marked lowering of the gastric acidity, but secondary ulceration had been known to follow all these operations. Of 100 cases of gastro-jejunal ulcer operated upon at the Mayo Clinic, and analysed by Balfour,[3] 20 per cent. were associated with anacidity, so that anacidity after gastro-enterostomy was not a certain protection against gastro-jejunal ulcer.

EDINBURGH OBSTETRICAL SOCIETY.

Reduction of Maternal Mortality.

IN the course of a valedictory address on Nov. 9th, the retiring President, Prof. R. W. JOHNSTONE, discussed the means of reducing maternal mortality. At present, he said, not more than about 9 per cent. of mothers in Scotland attended antenatal centres; if this number could be increased to 90 per cent. the maternal mortality question would cease to be a burning one. As regards intranatal care the first general principle to be borne in mind was that in the absence of complications a natural unassisted labour was always more favourable to both mother and child than an instrumental one. The pendulum had swung too far in the direction of instrumental interference. Antenatal examination enabled cases in which any difficulty was likely to be encountered during labour to be separated from those in which labour was likely to be normal. If all the cases in the latter category were allowed to remain normal

by being permitted to take their course except in the presence of true obstetrical indications, the effect would be a far-reaching improvement in results. Discussing the advisability of handing such normal cases in larger number over to the care of competent chosen midwives, he contrasted this plan with the alternative scheme for an official maternity service such as had been advocated by some obstetric teachers. He was of opinion that such a service would lead to midwifery becoming purely a specialty and he contemplated any such outcome with reluctance. He thought that the available beds for maternity cases ought to be greatly increased, not only in large centres but in country districts, and that in the latter at any rate patients might be encouraged to enter hospital and be there attended by their own doctors. This would tend to raise the standard of midwifery practice throughout the country without actually making midwifery an exclusive specialty. In industrial class practice, he said, midwifery was inadequately paid, and until the remuneration was better it could not be hoped that the standard of obstetric practice would be raised very much. The time given to the clinical study of midwifery in the curriculum should be greater, for it was absurd that the study of a vital subject like practical midwifery should have the same period allocated to it as to diseases of the skin and other minor specialties.

Reviews and Notices of Books.

GONOCOCCAL INFECTION IN THE MALE.

By ABR. L. WOLBARST, M.D., Urologist and Director of Urologic Clinics, Beth Israel Hospital. London: Henry Kimpton. 1927. Pp. 237. With 82 illustrations and 7 plates. 25*s*.

Dr. Wolbarst considers that a book on this subject is called for because there has recently been "a considerable advance in our knowledge of the treatment of male gonorrhœa and its complications." Whilst welcoming his treatise we do not agree that there has been much progress during the last decade. It is true that during and after the war many new methods were introduced, involving the use of new instruments and the application of electrolysis, diathermy, and cauteries; but as a result the mucous membrane of the urethra has often been subjected to trauma which has had effects more distressing than those of the gonococcal infection itself. The over-treatment of ten years ago is, therefore, giving place to the laissez-faire policy of pre-war days, and with the exception of diathermy hardly any method of treatment is now in common use which was not then employed.

Dr. Wolbarst, however, considers that advance has been made in physical therapy, intravenous and local medication, protein therapy, and, most important of all, by Belfield's method of washing out the seminal vesicles through the vasa. In his personal experience "covering several hundred cases, this operation has proved of inestimable value," and is the "ideal method of treatment in the average case of vesiculitis." Dr. Wolbarst employs diathermy not only in the treatment of such complications as epididymitis, arthritis, prostatitis, and vesiculitis, but also in cases of uncomplicated anterior infection. For this application to the anterior urethra he uses a straight electrode inserted down to the bulb, or in some cases electrodes applied externally to the lateral walls of the penis like a splint. His results in localised anterior urethritis seem to be as good as those obtained in this country in the treatment of prostatitis and epididymitis. The final chapter of the book is contributed by Mr. J. E. R. McDonagh, whose views are stimulating, though for the most part cannot be understood without reference to his previous publications. The treatment of gonorrhœa has, however, proved such a stone wall that an original thinker ought to be encouraged rather than discredited on the score that his statements ar unproven.

Taken as a whole Dr. Wolbarst's book is the cleares and the most complete work that has yet appeare on modern methods of treatment in gonorrhœa.

PNEUMOTHORAX AND SURGICAL TREATMENT O PULMONARY TUBERCULOSIS.

Second edition. By CLIVE RIVIERE, M.D. Lond F.R.C.P., Physician, City of London Hospital fo Diseases of the Heart and Lungs, and East Londo Hospital for Children. London: Humphre Milford, Oxford University Press. 1927. Pp. 31 10*s*. 6*d*.

THE second edition of Dr. Riviere's book is i several respects an improvement on the first, publishe ten years ago. During this interval there has bee no revolutionary change in pneumothorax treatment its technique has been perfected, and its popularit has been further established. But important advanc have been made in the surgical treatment of pulmonar tuberculosis, and this is why the author has advisedl included in the second edition several chapters o this subject. In Part I. the original 14 chapters hav grown into 19, and much new material has bee provided in connexion with such important problem as the reduction of adherent pleura and the duratio of the treatment.

Dealing in Part II. with the surgical treatme of pulmonary tuberculosis, the author has wise avoided operative details and technique. He giv an account of the underlying principles of the vario operations, and of their prospects of success as judg by the available statistics. In this way he enabl the busy practitioner to form an estimate of t value of these operations. In the case of pneumothor treatment a certain amount of experimentation often justifiable, for if the treatment is a failu it can easily be discontinued without the patie suffering much from the attempt. But the surgic operations entail pain and discomfort and leave litt room for a tactical retreat; infinite caution and wide experience are necessary if the patient is to fairly treated. Discussing the results of the surgic treatment of pulmonary tuberculosis, the auth writes: "In gauging their value it is well to rememb that they represent the work of those surgeons mo highly skilled in this branch of work . . . ." Prac tioners responsible for the choice of a surgeon w insist on choosing one who has successfully master this highly technical subject.

HYGIENE AND SANITATION.

By JESSE FEIRING WILLIAMS, M.D., Professor Physical Education, Teachers' College, Columb University. London and Philadelphia: W. Saunders Company. 1927. Pp. 344. 10*s*.

THIS book is intended to present to the beginner t fundamentals of hygiene and sanitation, and is wl adapted to that end. It opens with a brief elementa review of the history of health care in modern tim and lays commendable stress on the need for a cle understanding of the descriptive terms in common u Subsequent chapters are devoted to personal hygien the care of expectant mothers, of children, and of t aged and infirm; the dual rôle of hygiene and sani tion in the prevention of disease; lighting, heati and ventilation in relation to the home and t factory; and national and international organisatio for preserving and promoting the health of the peop Lists of books for collateral reading are supplied, a questions at the end of each chapter, which will b useful to teachers. We notice that measles is includ among the diseases spread by milk, a mode of tra mission which has not, so far as we know, be substantiated. A statement on p. 19, also, mig give the impression that Jenner lived and worl subsequently to Chadwick and Simon. Such sm defects hardly detract from the value of a very use little book.

RGERY OF THE EYE AND ITS APPENDAGES.

Chirurgie de l'Oeil et de ses Annexes. Third edition. By F. TERRIEN, Professeur de Clinique Ophtalmologique à la Faculté de Médicine de Paris. Paris: Masson et Cie. 1927. Pp. 646. Fr.100.

THE number of excellent text-books of operative gery of the eye which have been published of late ars by English, French, American, and German iters makes the choice between them somewhat barrassing. English readers, besides Grimsdale l Brewerton's text-book, have access in their own gue to Torok and Grout's work, and to Dr. Sweet's nslation of Meller. For French-reading students rrien's work, enlarged and revised in this edition, npetes on equal terms with that of Duverger and lter, which appeared last year. Terrien's book is re complete, describing not only the common erations, but a large number that are very seldom formed, including some which are not even ommended by the author. Thus, owing to the portance of the subject, the operations for intra-sular extraction of cataract, both that of Smith and t of Barraquer, are described in some detail, but the hor recommends them only in very exceptional umstances. It would be difficult to include all operations that have been proposed for glaucoma, the majority of them are described. The same lies to lid operations. The descriptions themselves adequate, and are greatly assisted by the very e number of figures illustrating the text. These ires are not ambitious—there are no coloured plates, instance—but they are clear, and serve their purpose nirably. Only here and there could we wish for re copious illustration, as, for instance, in the cription of excision of the lacrymal sac. Perhaps operation is not so popular in France as it is here. greater space and far more copious illustration is orded to the operations which provide drainage for sac through an enlarged opening into the nose. his book is comprehensive in most respects, and h as a work of reference and a guide to intricate cedure will be found of great value. Only as ards the newer methods of plastic surgery of the and socket that have been devised since the war reader unlikely to find what he wants.

ACTICAL NURSING.

Including Hygiene and Dietetics. Seventh edition. By the late HERBERT E. CUFF, M.D., F.R.C.S., Principal Medical Officer to the Metropolitan Asylums Board, London. Rewritten and enlarged by W. T. GORDON PUGH, M.D., B.S., Medical Superintendent, Queen Mary's Hospital for Children, Carshalton. London and Edinburgh: William Blackwood and Sons, Ltd. 1927. Pp. 754. 10*s.* 6*d.*

N this edition many changes have been made to t the requirements of the examinations for nurses ituted since the previous edition was published. new matter is chiefly in the sections dealing with etics, ward work and hospital administration, lin treatment, diseases of children, and the use of a-violet light and X rays. Over 150 illustrations e been added. A special feature is the inclusion the appendix of the questions, except those in tomy and physiology, which have hitherto been at the written examinations of the General Nursing ncil of England and Wales. References are given r each question to those pages on which the ropriate answer is to be found.

he book is simply and clearly written, and besides ng all the essential facts which a nurse is likely require, contains enough medical and surgical ails to enable her to understand the dangers of h disease and the aims of treatment. She may then her part with some knowledge of the principles g followed by the doctor in charge. In some places duties of the nurse, apart from those of the doctor, not stand out in sufficient relief. For example, in the paragraph on the nursing and treatment of pneumonia, although stimulants and bleeding are discussed, no mention is made of the great importance of frequent cleansing of the nose and mouth in preventing nose and throat complications. The sections on hygiene, bacteriology, and dietetics are simple and clear, and contain enough of the groundwork of these subjects to help a nurse in her practical work.

The book contains all that a nurse need know in order to pass her examinations, and much besides that is relevant. Dr. Pugh is to be congratulated on condensing so much into a handy volume, and on the excellent index provided.

THE SKIN: ITS CARE AND TREATMENT.

By ALBERT STRICKLER, M.D., Professor of Dermatology and Syphilis, Temple University Medical School. London and New York: Appleton and Co. 1927. Pp. 194. 5*s.*

THIS small volume can be described as a household treatise, since its contents can be readily understood by any adult layman. The author, who is well known on both sides of the Atlantic as an expert dermatologist, has done well to emphasise the importance of prevention, and no detail in the daily skin toilet has seemed to him too trivial for mention. Bathing and washing, the value and misuse of soaps, their relative causticity, the question of "hard" water, rules for diet, the special treatment of infants—all these and many other subjects are discussed in the simplest terms. A good deal of space is devoted to the prevention and treatment of acne in the adolescent, pityriasis of the scalp and its possible sequelæ, and such common ailments as chilblains, sunburn, urticaria, rosacea, and warts. It is interesting to observe that Prof. Strickler does not offer any wholesale condemnation of the use of cosmetics, which have gained an apparently unassailable hold on the women of to-day. He discusses them rationally and indicates some of the more obvious fallacies and dangers. This section is one of the most original in the book, and should exert a healthy influence over some of the many victims of unscrupulous beauty specialists. The low price of publication doubtless accounts for the absence of illustrations and diagrams; nor need this be deplored, for Prof. Strickler's object is to educate the public, not to teach them dermatology. His book is probably the best of its kind from American sources.

RECENT ADVANCES IN ANATOMY.

By H. WOOLLARD, M.D., Elder Professor of Anatomy, University of Adelaide; late Assistant Professor of Anatomy, University College, London. London: J. and A. Churchill. 1927. Pp. 302. 12*s.* 6*d.*

AN anatomist of the latter part of last century, seeing a book which deals with such subjects as the different sorts of sensations, or central retinal projection, or the origin of the cerebro-spinal fluid, might consider it a physiological work. It is not so to-day. Physiology looks at the structure of the body from the viewpoint of function, while anatomy considers function from the standpoint of structure, and there was, at one time, a marked tendency in each camp to forget what it was looking at in the excitement of discovering new methods of observation. Recent years, however, have seen a more reasonable outlook and, consequently, a nearer approach to each other of the two fundamental medical disciplines. Anatomists in particular, dissatisfied with the functional ideas offered to them, have been pushing their inquiries beyond the dissecting-room, into the laboratories and experimental theatres, and gaining new notions about the structures with which they deal. While much still remains to be done in the middle of the anatomical field, its boundaries are now widened to such an extent that it is difficult for those who are actively working in some particular portion of it to keep in touch with all the activities going on elsewhere.

Prof. Woollard's little volume is, therefore, very welcome. It does not profess to deal with all the studies which are included under the usefully comprehensive term "anatomy," for this would hardly be possible, but it gives a good idea of certain modern work. Beginning with an interesting account of Prof. Chambers's new art of microdissection, the author goes on to a consideration of some aspects of tissue culture; subsequent subjects, in addition to those mentioned in our first sentence, include ovulation, the Miller ovum, growth centres and organisers, morphogenesis of nerve-fibres, vital staining, origin of blood cells, postural organs, the red nucleus, extrapyramidal system, cerebellum, and X ray anatomy—a good set of important matters, each chapter having a reference list of cited literature. Much of the work has been done in America, where a happy combination of enthusiasm and capital has opened up great possibilities. It is well that all these views should be put before us, although it remains to be seen whether some of them will stand the test of time and further research. There is much information in this book which will, we think, be new even to some anatomists, and its success is certain. In the next issue the author might look to his Latin grammar. The book is of handy size, well printed, and clearly illustrated, and a good member of an excellent series.

HYPOTENSION.

By ALFRED FRIEDLANDER, Professor of Medicine, University of Cincinnatti. London: Baillière, Tindall and Cox. 1927. Pp. 193. 13*s*. 6*d*.

THIS book is a reprint of an excellent article which appeared in an American medical journal and has already been the subject of comment in our pages (THE LANCET, August 13th, p. 345). Prof. Friedlander deals in succession with all the conditions in which a lowered blood pressure reading may be obtained, and with the various tissue extracts and other substances known to have a hypotensive action. His useful monograph should find many readers.

THE ELECTROPHONOÏD METHOD OF ZÜND-BURGUET.

By MACLEOD YEARSLEY, F.R.C.S. London: William Heinemann. 1927. Pp. 108. 5*s*.

THIS small book constitutes a manual of Dr. Adolphe Zünd-Burguet's method for the treatment of chronic deafness by auditory re-education, and it has been read by Dr. Zünd-Burguet who, in a modest foreword, suggests that the originality of scientific work "consists as much in the strictly correct interpretation of known facts as in the presentation of personal discoveries," the words being equally applicable to himself or Mr. Macleod Yearsley.

In a brief résumé of the methods employed during the past 100 years in the treatment of chronic deafness, Mr. Yearsley points to Victor Urbantschitsch, of Vienna, as the real precursor of auditory re-education. His method was much discussed from the obvious point of view that the improvements related by him lacked all anatomical explanation, to which he replied some 40 years ago (much as Zünd-Burguet replies to similar criticism to-day) that the trial of his method would prove its success, and both workers consider that re-education may be found of value in nearly all deaf cases. A description of the electrophonoïd apparatus for the mechanisation of the human voice is accompanied by an explanation of the scientific principles upon which its claims are based, and is followed by a wise chapter upon the need for a scrupulously careful examination of the patient before deciding upon the advisability of applying the treatment; the chapter concludes with a model case-sheet, leaving spaces for charting the various findings under general and special history, response to tuning-fork tests, and acoumetry. The results of the practical application of the method are asserted to be pedagogic and therapeutic, the patient learning to listen, while the pathological conditions—certain of them, at any rate—are definitely ameliorated. A section dealing with the indications and contr indications for the method suggests that all cases deafness, not caused by a complete destruction the organ of Corti, may be suitable for audito re-education; and in amplification of this vie Mr. Yearsley quotes Dr. G. C. Cathcart's figure published in THE LANCET some two years ago,[1] ar adduces, also, the results in a series of 41 cases und his own care.

It is well known that differences of opinion ex as to the value of Zünd-Burguet's method. But view of the wise decision of the Otological Section the Royal Society of Medicine to set in motion international research into the subject of otoscleros this method is sure to come under review, so th Mr. Yearsley's exposition of it is timely.

LIFE ASSURANCE IN THE TROPICS.

A Pocket Guide to Medical Life Assurance. Seco edition, revised and enlarged. Compiled JEHANGIR J. CURSETJI, M.D., L.R.C.P., L.R.C. Chief Medical Officer, The Oriental Life Assuran Co. Bombay: At the Times Press. 19 Pp. 92.

THE problems of life assurance in tropical countr are in some ways more difficult than those in mo temperate and equable climates. Apart from t special diseases incidental to life in hot climates a the marked incidence of parasitic infections, t influence of racial habit demands close consideratio The statistical data available to medical officers insurance companies overseas are at present l complete and perhaps less reliable than those up which premiums for lives in this country are bas The small guide before us, which is now in its seco edition, has been compiled by Dr. Cursetji to affo help in these matters. He has had a considera experience as medical examiner in India, mo especially as chief medical officer to the Oriental L Assurance Company. His book is presented in t forms, one intended for head office use, the oth for the occasional examiner. The author stresses t importance of securing full evidence of identificatio since impersonation and fraud are not infrequent India; statements in regard to age and family histo are frequently found to be unreliable. On the oth hand, addiction to alcoholic drinks is unusual, thou other intoxicants, such as bhang, ganja, and opiu are extensively consumed.

It is difficult for chief medical officers in t country to assess the question of physique in Indi applicants. The data included in tables as an append to this book in regard to the average height, weig chest, and abdominal measurements of Indi assured lives should be very helpful. These tab comprise details scheduled in over 51,000 liv examined by the Oriental Government Securi Life Assurance Society during the years 1914 to 19 carefully scrutinised under the close supervision the actuary, Mr. Douglas Forrest. There is also table giving the expectation of life in Indian lives the basis of the mortality experience of the sa Company over a period of 39 years. These statist comprise details in regard to Hindus in different pa of India, Mohammedans, Parsees, and Indi Christians, by far the largest number being Hind Considerable attention is paid to the recording blood pressure as a part of the medical examinatio Most companies now insist upon a record of blo pressure, at any rate in lives over 50; the autho clear practical description of the methods of recordi the systolic and diastolic pressures should be valuab The importance of the moral hazard in life assura is discussed, and, although this is a question rath for the management, it is one upon which the medi examiner should be prepared to express an opinio

Dr. Cursetji is concise and practical throughou he has a real grasp of the special problems of insura medicine, and his guidance will be found helpf more especially to the occasional examiner.

[1] THE LANCET, 1925, i., 968.

THE LANCET.

LONDON, SATURDAY, NOVEMBER 26, 1927.

THE LORD CHIEF JUSTICE ON CRIME AND INSANITY.

LORD HEWART'S Lloyd Roberts lecture, delivered before the Medical Society of London on Nov. 16th, and reported at length in another column, was a characteristically lucid exposition of the strict legal view of the criminal responsibility of the insane. But nothing is more clear than that the Lord Chief Justice will take no step to reconcile the different opinions which he ascribed to the legal and medical professions. He repudiated even the slight concessions which the Atkin Committee recommended In 1922, when the trial of RONALD TRUE had given the public the impression that all was not well with the administration of justice in such cases, the Lord Chancellor appointed a Committee to consider what changes, if any, were desirable in the existing law, practice, and procedure relating to criminal trials where the defence of insanity is raised. The predominantly legal character of the committee was unmistakable. The chairman was Lord Justice ATKIN. Besides the two law officers of the Crown, the other members were Sir HERBERT STEPHEN, with his unrivalled knowledge of trials in the assize-court, Sir RICHARD MUIR (then Senior Treasury Counsel at the Central Criminal Court), Sir ARCHIBALD BODKIN (Director of Public Prosecutions), Sir EDWARD TROUP (lately permanent Under Secretary at the Home Office, perhaps the sole member of the Committee who had never prosecuted or defended a prisoner), Sir ERNLEY BLACKWELL (the Home Office legal expert), and the late Sir EDWARD MARSHALL HALL. The Lord Chancellor having thus appealed for guidance to a body which certainly could not be accused of any bias towards the medical view, the Committee presented a unanimous report; it recommended two changes in the law, changes which fell far short of the proposals of the Medico-Psychological Association, but which coincided reasonably with the more conservative suggestions of the British Medical Association. What, however, the Lord Chancellor's Committee recommended, the Lord Chief Justice's lecture disapproves.

The Atkin Committee's main proposal for the alteration of the law was the recognition of the defence of uncontrollable impulse. "It should be recognised that a person charged criminally with an offence is irresponsible for his act when the act is committed under an impulse which the prisoner was by mental disease in substance deprived of any power to resist." Lord HEWART will have none of this. He will allow no medical witness to say that A's impulse was uncontrollable for fear that B and C and D should relax the effort to control their own. Lord HEWART is frankly afraid of the medical witness. The crucial question at the trial would be whether the accused was acting under an irresistible impulse. "Would there be any material or guidance at all except the medical opinion which the prisoner might be fortunate enough to be able to adduce in his favour, contradicted by the medical opinion which might be offered on the part of the prosecution?" If the issue in a trial is a matter of medical testimony, why should that testimony be ignored? It is a common enough practice in a criminal court to take the evidence of the prison doctor as to a prisoner's state of mind. Is the opinion of other doctors who have made a special study of mental disease to count for nothing? The Lord Chief Justice discounts the Atkin Committee's recommendation because it named infanticide as a known example of uncontrollable impulse. The Infanticide Act, he says, has made special provision for this class of offence. But all that the Infanticide Act has done is to make it lawful to reduce the charge of child murder to some lesser offence, and, as our columns showed last week, the statute withholds even this slight measure of relief if the infant is four weeks old. The Infanticide Act can scarcely be accepted as a sufficient substitute for the Atkin Committee's recommendation that the defence of uncontrollable impulse be legally recognised. The failure to implement the Committee's main recommendation extends also to its second and minor proposal for the alteration of the law. It recommended the abolition of the meaningless verdict, "Guilty but insane." As the Committee's report pointed out, this verdict is one of acquittal; the word "guilty" in criminal trials should connote criminality only; the word "insane" indicates that the criminality was negatived by irresponsibility. On any showing, this illogical verdict should be banished from our courts; the necessary legislation is presumably denied because of the official view that no change could be a change for the better.

LABORATORY BENEFIT.

THE recent annual conference of insurance committees, held at Harrogate, agreed to press for the inclusion of expert medical advice and treatment and in particular of laboratory service as part of the medical benefit under the National Health Insurance scheme. This, it will be remembered, was one of the recommendations of the Royal Commission, and the conference expressed satisfaction at the steps already taken on their own initiative by certain insurance committees to provide for pathological investigation. It is a healthy sign of awareness on the part of insurance committees throughout the country to the needs of insured persons that these matters should have engaged the attention of the conference; but the fact that schemes, such as that recently introduced in Lancashire, are being promulgated by individual committees is not without its drawbacks and dangers. In a service such as national health insurance it is desirable for the machinery to be standardised. Local differences in practice must lead to increased complexity of administration and consequent unnecessary labour. That was fully recognised by the council of the National Association of Insurance Committees, which, while taking cognisance of sporadic arrangements, insists that nothing short of a laboratory service established upon a national basis can be a satisfactory complement to the national medical service.

The only laboratory activity at present recognised by the health insurance system is the manufacture of vaccines. A panel practitioner may send a patient to a pathologist for a vaccine and for the preparation of this a reasonable payment will be made; no funds, however, are provided for the performance of any investigations directed towards ascertaining whether a vaccine or some alternative line of treatment is desirable. The pathological laboratory has of late years become so

essential an instrument of diagnosis that it is not surprising that efforts have been made in many parts of the country to remedy the shortcomings of the health insurance system in this respect. A simple and obvious expedient is for the practitioner who requires the aid of a laboratory in the diagnosis of his patient to send the said patient to a pathologist ostensibly for the preparation of a vaccine, but actually that the pathologist may make such investigations as may be necessary, the pathologist on his part charging a fee ostensibly for the preparation of a vaccine, but actually for the examinations performed. This subterfuge can hardly be regarded as satisfactory, but it is the line of least resistance for the active and intelligent practitioner in many parts of the country. Somewhat less surreptitious arrangements, inaugurated at the instance of various insurance committees, have been arrived at in certain parts of the country. Of these arrangements there are three general forms of which typical examples are in force in Lancashire, Cheshire and Flintshire, and the West Riding of Yorkshire.

(1) Under the Lancashire scheme the Wigan Royal Infirmary has agreed in consideration of a payment by the insurance committee of £500 to supply outfits for the collection and transmission of pathological specimens to all panel practitioners in the area of the committee and to perform all pathological investigations for insured persons in the area without further charge. (2) The Cheshire and Flintshire committees have an arrangement with the Chester Royal Infirmary by which the latter undertakes to perform pathological investigations for insured persons at a reduced rate; a similar scheme is in existence in Wolverhampton where it was inaugurated by the Wolverhampton and Staffordshire General Hospital. In this type of scheme the doctor sending in material assumes responsibility for the payment of the fee, which he may or may not recover from the patient. (3) In the West Riding of Yorkshire a scheme was inaugurated some years ago by which the county council laboratory offered to provide reports of pathological material for insured persons, free of any charge, in addition to the service specifically provided out of the public funds.

Of these three systems the first two involve arrangements between the insurance committees and those hospitals to which the patient will probably be admitted if in need of hospital treatment. This coöperation between the general hospitals and the insurance service offers obvious advantages, one of the greatest of which is the provision of a steady flow of paid work which would enable many voluntary hospitals, not now able to do so, to maintain a pathological department, and would assist those which already have them to increase their efficiency. Such departments are expensive to run and demand expert direction, which must be paid for. It is probable that few measures would tend more to raise the standard of all our medicine than the establishment of a network of pathological departments in connexion with the voluntary general hospitals. Many such, of course, exist at the present day; they serve as rallying points for the medical activity of their neighbourhood in so far as investigation and research are concerned. Elsewhere the newly settled practitioner too often finds himself cut off from the facilities for clinical investigation which he enjoyed in his teaching hospital, and his work is accordingly hampered. Few practitioners are out of reach of a general hospital, but many of these are without adequate pathological departments; this is a state of affairs which is being remedied as rapidly as possible in the circumstances, but it would be even more readily remedied could the governing bodies of voluntary hospitals be assured of a steady, even though small, income for their pathological departments when established. The system inaugurated in the West Riding appears to involve the use of public money for a purpose for which it is not specifically provided, and, if it became general, would lead to the locking up of a large amount of clinical data where they could be of no further use. Commendable as they are, the Lancashire and Cheshire and Flintshire schemes are in some respects open to grave criticism. As regards the former the difficulties of estimating the lump sum which shall represent an adequate repayment for work performed are obvious; as regards the latter the fees charged to insured persons must in the nature of things, so long as no financial responsibility is assumed by the insurance committee concerned, afford no adequate remuneration to the hospital undertaking the work. There is no dissentience as to the need of a pathological service for insured persons; there is grave danger that if the decision is much longer deferred disturbing differences in local practice in its provision may grow up. The time would appear to be ripe for concerted action.

MEDICAL WORK OF THE MINISTRY OF PENSIONS.

ON Saturday last, at the annual dinner of the Sussex Medico-Chirurgical Society, the Minister of Pensions, Major G. C. TRYON, spoke interestingly upon the urgent need for accurate medical knowledge that had been revealed in the course of the work of the Ministry. All who know how extensive and valuable that work has been, and still is, will endorse his statement that even amongst doctors there are too few who realise either its amount or the difficulty of the circumstances in which it has been done. How often, for example, that work has been of pioneer nature, because the results of war were outside the ordinary experiences of either civilian or doctor. An example given by Major TRYON to illustrate the provision of his department was a particularly apposite one, for he pointed out that, long before the recent Royal Commission on Lunacy made its report, the Ministry of Pensions had established hospitals for borderland cases; while as an example of promptness in the employment of medical discovery we are reminded that the Ministry set aside special wards for the effective treatment of diabetes as soon as the properties of insulin became known.

The first duty of the Ministry of Pensions, when it came into existence, was to investigate and decide the exact nature of the disability of any applicant—the extent to which that disability affected the life of the subject, for on this must depend the just assessment of compensation. The problems that thus presented themselves before the medical boards, which were established promptly throughout the country, were not easy, for in many directions there were no scientific precedents upon which decisions could be based. And the terms, "entitlement" and "assessment," were themselves novel, so that the boards were dealing, in their early days, with conditions where accepted knowledge proved no general guide and were expected to conform in their judgments with an unfamiliar scheme of categorisation. Further uniformity of procedure had to be ensured throughout the country. This was guaranteed by the coöperation on the boards of whole-time medical officers, specialists, and general medical practitioners, so making up an average of medical opinion, and that the average was capable of even-handed justice

endering its verdict is proved by the emergence of he boards with credit from considerable hostile riticism—criticism that was natural, no doubt, ecause of the sad quality of the instances of ardship under discussion, but which was none the ess usually unwarranted.

Following "entitlement" and "assessment" came reatment when the needs of the Ministry were otoriously greater than could be met by the ospitals of the country, civil and military, so that he Ministry was compelled to establish a network f hospitals and clinics throughout the country for he orderly development of this work. Major TRYON aid: "As the number of cases requiring treatment iminished, it became possible to concentrate cases f similar character in a few specially equipped stitutions—e.g., cases of dysentery and other ropical diseases; paraplegics and epileptics. The iscellaneous category of war neurosis resolved itself s time went on into the definitely insane, the borderne case, the true neurasthenic, and the mentally efective. For all these classes special arrangements ere made. For the insane the Ministry established close liaison with the Board of Control and eventually ranged for the allocation of separate wings in two rge mental hospitals for the treatment of those nsioners whose mental state permitted them to ppreciate the special accommodation provided. In ddition, patients discharged on trial are specially ccommodated for a time in Ministry hospitals, so s to minimise the difficulties of sudden transfer om asylums to civil life." The Minister's summary no way exhausts the story of combined and indidual effort undertaken for the treatment of penoners. The Royal Colleges, the Medical Research ouncil, and many distinguished clinicians have been gaged throughout in advising and collaborating ith the Ministry, and the need remains for a conuance of their labours. According to the estimate the Ministry of Pensions 3750 beds are still required the hospitals of the Ministry, while 5250 outtients are under its care. There is no room for laxation of activity, but the results achieved give od promise for the future.

ELIZABETH GARRETT ANDERSON HOSPITAL.—Over 000 was subscribed at a dinner in London last week in t of the fund for the extension of this hospital.

BIRMINGHAM HOSPITALS.—The new surgical block 120 beds which has been added at a cost of £100,000 to e Queen's Hospital was opened last week by the president, Charles Hyde, Bart. The additional accommodation nsists of three large operating theatres, six wards, two rilising rooms, three anæsthetic chambers, and conmitant apartments. The walls of two of the theatres e covered with grey opaque glass; in the third the glass mottled green. The board have had to realise the whole the hospital's available investments, but a further £15,000 needed to cover the capital expenditure, while the addins involve an increased annual outlay of £15,500.—The ort of the Hospitals Committee of the Birmingham ard of Guardians emphasises the heavy increase that has ken place in the work of the Dudley-road and Selly Oak spitals. In-patients have grown by more than 3000 to 989. At Dudley-road the out-patients have nearly abled; at Selly Oak they have exactly doubled. These ures eclipse all previous records—indeed, Dr. F. W. Ellis, chief medical officer, states that the continued increase ring the last seven years "probably creates a record for y hospital administration in the country." Major R. ey, assistant to the treasurer of the Royal Berkshire spital and organiser of the contributory scheme of that titution and the associated hospitals, has been appointed anising secretary of the Birmingham contributory scheme ich comes into operation on Jan. 1st.

Annotations.

"Ne quid nimis."

A YEAR OF CANCER RESEARCH.

IN the twenty-fifth annual report of the Imperial Cancer Research Fund Dr. J. A. Murray presents a brief résumé of a year's work at the laboratories of the Fund which he directs. Tumour material from these laboratories has as usual been supplied to assist investigators all over Europe, some of whom have responded with a similar courtesy. Ten papers by members of the staff have appeared in scientific journals, amongst them the Linacre lecture on Multiple New Growths, which we printed last month. Dr. Murray specially notes an effort made to meet the complaint frequently launched against laboratory workers on cancer research that they so seldom provide general summaries of the state of our knowledge suitable for the educated layman. In response to an invitation Dr. W. Cramer prepared such a summary which was published in the *Nineteenth Century and After* for April and May last. Only those who have attempted the task, writes Dr. Murray, can have any idea of the difficulties involved in conscientious work of this kind. The constant wariness which must be exercised to secure accuracy without the use of technical terms, or ordinary words which have acquired a special technical significance, makes the preparation of such articles a time-consuming labour. Two matters of special interest are mentioned at greater length. The work under the Atholstan grant at the Stroud laboratory has advanced sufficiently to permit of publication. In one paper Dr. A. M. Begg dealt with the successful propagation of very slowly growing fibro-sarcoma of the fowl. This was at first thought to be a benign tumour, but the occurrence of metastases in one of the propagated tumours relegates it definitely to the malignant category. This interesting observation draws attention to the close similarity between the benign and malignant tumours. In his second paper [1] is described a filtrable endothelioma of the fowl easily propagated by grafts of living tumour tissue and leading to the formation of large masses of new growth with metastases in internal organs and in superficial lymphatic glands. In addition growths can be produced by the injection of dried material and of cell-free filtrates. In this respect, writes Dr. Murray, the tumour behaves in the same way as the sarcomata of the fowl described by Rous and others, and Dr. Begg has been able to carry out inactivation and reactivation experiments on the model of those devised by Dr. Gye with the Rous tumour, with similar results. The tumour used by Dr. Begg differs in structure from the fowl sarcomata previously described, and provisionally it is regarded as arising from endothelial cells of the blood-vessels. A visit paid by Mr. H. G. Crabtree and Dr. Cramer last summer to the Kaiser Wilhelm Institute of Prof. O. Warburg in Berlin leads Dr. Murray to include in his report a short statement of Warburg's biochemical conception of the nature of cancer. The metabolism of carbohydrates supplies the chief energy-yielding processes for all the tissues of the body. Normal tissues obtain energy for growth by a pure oxidation process resulting in the production of carbon dioxide and water. If they are deprived of oxygen they fail to survive, on account of this restriction in their method of utilising carbohydrate. Tumour tissue, Warburg finds, has not merely this capacity to break down carbohydrates by normal respiratory processes, but also, when deprived of oxygen, can derive sufficient energy for survival by breaking down the carbohydrate (in the manner used by yeasts)—i.e., by a splitting process yielding lactic acid as the final end-product. Even when the supply of oxygen is not restricted tumour tissue makes use of both the oxidation and splitting processes, thus betraying a mode of metabolism

[1] THE LANCET, 1927, i., 912.

which is characteristic, and differentiates it from all other normal tissues, with the curious exception of the retina. On this basis Warburg suggests a hypothesis accounting for tumour origin. He conceives that normal tissues are not homogeneous but consist of a mosaic of cells, growing and surviving by oxidative breakdown of carbohydrate, interspersed with isolated cells which have the dual capacity of utilising carbohydrate by the oxidation or splitting processes. Under abnormal conditions, when any group of cells suffer an oxygen deficiency, the chances of survival are greatly in favour of the latter cells, which then provide the nucleus for subsequent development of malignant tissue, which retains this characteristic method of carbohydrate metabolism. The total expenditure of the Fund during the year amounted to just short of £12,000, of which office expenses absorbed less than 9 per cent.

THE USE OF WHITE LEAD IN PAINTING.

THE Lead Paint (Protection Against Poisoning) Act was passed on Dec. 15th last. Under Section 2 of this Act women and young persons were prohibited from painting buildings with lead paint as from the 19th day of this month except in the case of women so employed at the date of the passing of the Act. Two exceptions were, however, made to this prohibition in favour of (1) persons employed as apprentices, and (2) women or young persons employed in special decorative or other work, not of an industrial character. An Order just issued by the Home Office now makes these exceptions more precise. Its effect is to relax the prohibition under Section 2 of the Act (1) in the case of any male young person employed under an indenture of apprenticeship or under an established custom of regular apprenticeship (subject to the condition that his name, age, and the date on which he was first engaged as an apprentice are entered in a separate list attached to the register of employees which the employer is required to keep); and (2) in the case of any woman or young person employed in "the execution of wall or ceiling paintings, or any similar work of decorative design." Nothing in this Order, it should be noted, will relieve any employer from the obligations imposed by the regulations contained in Section 2 of the Women and Young Persons (Employment in Lead Processes) Act, 1920.

Those who would gain a concise view of the present use of white lead in the painting industry should refer to a volume [1] just issued by the International Labour Office at Geneva, wherein is brought together under one cover information gathered from all over the world. Previously the only volume claiming to cover similar ground was that compiled by F. L. Cantineau in 1921 [2]; but this was written definitely to present the case against white lead. The new volume is the outcome of the discussion which took place at the third session of the International Labour Conference, held at Geneva in 1921, when it was unanimously decided that delegates should advise their Governments to take steps to prohibit the use of white lead in paint used on the interior of buildings, while adopting stringent regulations where paint containing lead is used on the outside of buildings. The volume opens with an historical sketch of the movement against the use of white lead; it seems that the campaign originated and has been followed up by countries where zinc white, the great rival of white lead, is manufactured, while the leading opponents have been the countries where this material is not manufactured. The medical aspect of the question is then fully stated. The risk to which painters are exposed arises nearly entirely from the inhalation of lead-containing dust generated when painted surfaces are rubbed down dry, although the possibility of danger from inhaling turpentine vapour cannot be excluded. Statistical data indicate that the lead risk for painters is not confined to one country or one climate; it is widespread. Even the advocates of the continued use of white lead in paint allow the existence of the risk. They claim, however, that dry rubbing down can be abolished in favour of using waterproof sand-paper; recent experience indicates that the hopes entertained from this innovation are not being entirely fulfilled. Technical information is given as to the value of different paints and their costs; the economic aspect of the problem appears to be somewhat in favour of white lead. Next follows a discussion of legislative procedure adopted in different countries; two courses are open, either prohibition or strict regulation of the use of lead. In this and other sections of the volume the relevant information is stated fairly and without bias. Many of the facts, technical details, and health statistics are derived from work done on behalf of different committees, by experts in Great Britain and in other parts of the Empire. Thus we learn how two committees appointed in 1911, one to consider the danger arising from lead in paint used upon buildings and the other upon coaches and carriages, both reported in favour of prohibiting the use of lead in paint; that simultaneously with the holding of the conference at Geneva in 1921, a further committee was appointed which recommended that the conclusions arrived at in Geneva should be adopted; and that the Government, with this technical advice coming from its own experts before it, saw fit to adopt a code of regulations made under the Factory Act for the painting of coaches and carriages, and another code under the 1926 Act already mentioned. The book contains a number of valuable tables and useful graphs, and includes among its appendices the official report of the 1921 Conference.

THE STORY OF A PHARMACY.

IN the year 1715 Silvanus Bevan, apothecary, and afterwards Fellow of the Royal Society, took over the lease of premises in which the poet Pope was born. The pharmacy thus established in a small court off Lombard-street not only enjoys prestige as the oldest of its kind in London, and as the cradle of a business of world-wide scope, but also has sent out distinguished workers into the fields of pharmacognosy, botany and chemistry. Most of the early proprietors were members of the Society of Friends; and in the troubled international conditions of the late eighteenth century the formation of an overseas connexion was not accomplished without many delays and hesitations occasioned by privateers, conscience, or both. We find, for instance, one of the Bevans writing to a certain Dr. John Gill, of Barbados, in 1779: "... the books none specified are omitted that are in print except 'Chesterfield,' the 'Polite Lady,' and the 'United Friends.' I hope thou wilt excuse the freedom. From what I have seen of the first of these I know it is calculated to recommend folly, vanity and vice . . . ." The main interest, however, of the story, so well told by Mr. Cripps,[1] lies in the contributions to various sciences made by men who were either partners in the firm or near relatives. Daniel Hanbury, joint author with Flückiger of "Pharmacographia," was an accurate, highly-trained observer in pharmacognosy and in botany: he accompanied Sir Joseph Hooker to Palestine in 1860, and during the last few years of his life collaborated with his brother, Sir Thomas Hanbury, in stocking the garden at La Mortola, which is still one of the glories of the Italian Riviera. Botanical investigation has also been carried out by Mr. F. J. Hanbury, the owner of a remarkable rock garden in Sussex. From 1797 to 1806 William Allen, then head of the business, had as partner Luke Howard, who afterwards founded the

[2] La Céruse. Paris and Liége. 1921.

[1] Plough Court: The Story of a Notable Pharmacy, 1715–1919. Compiled by Ernest C. Cripps, M.P.S. London: Allen & Hanburys, Ltd. 1927. Pp. 227. 10s. 6d. (to medical practitioners, 5s.).

portant manufacturing concern now identified with e chemicals, and especially with quinine. During ose nine years many small-scale experimental ocesses were tried at Plough-court, and incidentally was realised, with the assistance of two outbreaks fire, that the heart of the city was not the ideal ace for the production of chemicals. John Thomas arry, who was admitted a partner in 1818, had a ghly individual method of dealing with such oubles. Finding, one Sunday morning, that smoke s issuing from a cupboard, he pasted strips of paper er the crevices and sat down to read his Bible, rrectly estimating, as it turned out, that the supply air would soon be exhausted. Barry is chiefly nembered by his invention of evaporation in cuo, the details of which were given in a paper esented to the Medical and Chirurgical Society in 19. William Allen, Barry's senior partner, became degrees a figure of European fame. A friend of the ke of Kent, Queen Victoria's father, he took a ding part in religious and humanitarian projects ich had the Duke among their patrons, and velled extensively to promote their success. The ume in which the story is told is admirably printed l illustrated, although it is odd that none of the npilers (of whom there have been three) has seen to correct "the Linnæan Society" and "Sir mphrey Davy." But the difficult transition from record of past achievement to the description of sent methods of manufacture has been accom- shed with discretion.

THE INVESTIGATION OF OTOSCLEROSIS.

AT a recent meeting of the Section of Otology of Royal Society of Medicine the President, Mr. S. Fraser, delivered an interesting address upon sclerosis, in the course of which he made a posal for a national investigation of the condition, ing that, while the problems appeared to concern logy alone, for their satisfactory evaluation the peration of other branches of the medical profes- n was required. "Some medical men failed," he l, "to diagnose the disease when confronted with it. en he began the study of otology in 1904 he spent ny useless hours in the hospital in testing patients o were supposed to be suffering from chronic is media, and who showed no improvement after ldle-ear inflation. It had since dawned on him that sclerosis was not an uncommon disease, and he nd that 10 per cent. of his patients suffered from it. he victims of it had been exclusively old, or past ldle life, it would not be so serious, but most of cases were in young people. Females were most cted, in the proportion of three females to one e. At least 50 per cent. of the subjects of it gave istory of deafness in the family. Microscopical mination carried out in early stages showed areas pongy bone in the labyrinthine capsule and at the erior margin of the oval window. Some of the es had also fragility of bones and blue sclerotics. Albert Gray's estimate was that 1 in every people suffered from otosclerosis. In its produc- n the main fault seemed to lie in some abnormality ndocrine glands, but inquiry had yet to go a long before any association could be established ween this disease and malformation or inadequacy ductless glands." Mr. Fraser went on to point that careful researches on the subject were now ceeding in America, but he deprecated waiting the American results, believing that coöperation better than competition, and that an international iry would be the most potent means of arriving the truth. The Otological Section thoroughly orsed the proposal which his words led up to—nely, that a central committee should be formed the Section to coördinate and organise research of vide character, the suggestion being to enlist help of the large hospitals and teaching ools of the United Kingdom. The proposal supported by Mr. Sydney Scott, Dr. Kerr e, Sir William Milligan, Sir James Dundas-Grant, Mr. G. J. Jenkins, Mr. Herbert Tilley, Mr. J. F. O'Malley, and Dr. Dan McKenzie among others, and the council of the Section was empowered to act in accordance with it.

HEALTH EDUCATION OF THE PUBLIC.

Sir Arthur Keith, in an admirable after-dinner speech which we report elsewhere (p. 1149), remarked on the real difficulty of getting through to the public with scientific medicine. Year by year young men and women, equipped with the spirit and knowledge of their craft, go out into the world to succumb to the craving for magic which lies deep in human nature. The British Association, of which he is this year President, has for its central aim to share the knowledge of trained observers with the public at large. Another agency for the same purpose is the League of Red Cross Societies, which publishes a monthly review in three languages, of which the English edition is called *The World's Health*. The contents of this review are not copyrighted, reproduction of the articles being welcomed, provided that due acknowledgment of their source is made. A special number for October deals with certain problems of health education. Dissemination of knowledge, as Sir George Newman lays down in a foreword, is useless unless it is in a form readily understandable by those to whom it is addressed. The channels along which knowledge should be made to flow are five in number: (1) sanitary environment; (2) healthy race; (3) resistant body; (4) methods of reducing mass infection; (5) early diagnosis and treatment of disease—and the field for public education in these matters is boundless in extent and full of opportunity. Dr. René Sand, who advises the League on popular health education, remarks that up to quite recent times it was possible for a man to assume high responsibilities in mercantile life without having the slightest notion of the importance of hygiene in industry; and for citizens to found families while being quite ignorant of domestic or sex hygiene. He deprecates the use of technical arguments in matters of diet, and advocates simple advice along the lines of what might be called intelligent omnivorousness. The place par excellence for health education of this kind is in the schools. It is a side of the work which the school medical service, as at present constituted, cannot adequately tackle, and there is urgent need to improve the standard of health knowledge among the teaching staffs in all the schools of the country, and, having done it, to send them out with a real desire to teach what they know. Twenty minutes a week devoted to the simple things of health in every school would within ten years do away with the need for most of the posters and pamphlets which Dr. Sand deals with so well. Any practitioner having to deal with young persons in industry will realise that one of the most hopeful ways of attempting to bridge the "gap" from 14–16 years of age in the medical benefit is so to educate children at school in the care of their health that they will be able in no small measure to bridge the "gap" for themselves by the simple method of avoiding sickness. Common-sense rules, devoid of fussiness or of the technicalities which Dr. Sand condemns, will, if inculcated at school during the plastic age, last as an abiding asset through life. There are many excellent black-and-white reproductions of various health propaganda posters in this number of *The World's Health*, together with a coloured inset of posters from different industries in all parts of the world. These are chiefly attempts to educate workmen in accident prevention. The art of producing attractive posters is comparatively new, and the specimens here given are good of their kind; but it is necessary to be aware of certain drawbacks to their use. Employers may spend much money on these things and forget the less spectacular but more important side of health education—namely, the written and, to a still greater degree, the spoken word. There is one curious omission from this health educational number—at

a rough computation 20 per cent. of the loss to industry in sickness is due each year to the common cold, which many believe to be largely preventable by more careful attention to ventilation and proper working temperature.

AVERTIN.

SOMEWHAT conflicting reports come from Germany regarding the recently introduced narcotic, avertin [1] (E 107, tribromethylalcohol). Some surgeons find that the anæsthesia it produces is as efficient as any that they know, besides being more pleasant, whilst others declare that the dangers of avertin put it out of court as a means of anæsthesia in practice. Experience is not yet very wide—some 3000 cases form the largest series yet reported—but it is probable that a definite generally held opinion will eventually be forthcoming as to the advisability of adding avertin to the commonly used anæsthetics. British anæsthetists would naturally like to play a part in the formation of this opinion by investigations of their own, and we are glad to know that through the zeal of Dr. Fritz Eichholz and the good offices of Dr. H. H. Dale, a certain amount of avertin is likely to be available in the near future for a limited number of clinical trials in this country. It is obvious enough from what has already been done that the solution of avertin requires of the anæsthetist special care in its preparation and testing shortly before use, and that the risks associated with all forms of rectal anæsthesia are certainly no less, even if they are no greater, with avertin than they are with ether.

WATER DIVINING.

Prof. J. W. Gregory, the well-known geologist, in a paper read on Nov. 17th at the Public Works, Roads, and Transport Congress, gave an historical account of the alleged art of water divining with descriptions and summaries of critical tests to which the method has been subjected. The use of the divining rod goes back to ancient times, and even to-day public bodies employ diviners to recommend sites for well-sinking. Some supporters claim that the rod responds to external physical influence, and the diviner himself usually denies exerting any muscular force when the rod is strongly moved. That such a widespread and powerful influence should exist and be incapable of other experimental demonstration is difficult to reconcile with scientific knowledge, and all the movements of the rod can be produced by anyone who cares to learn how to hold it. An alternative view admits the part played by muscular action, but retains a claim for the mysterious by postulating a kind of second sight, by which the diviner senses the presence of any object for which he is searching, such as oil, metals, buried treasure, letters in an envelope, future events, underground water, or some special person. This frankly places the divining rod in the same category as planchette and other spiritualist mechanisms. A third explanation brings such mechanisms into relation with other phenomena that have already been investigated by medical psychologists. The theory of dissociation of consciousness, which conforms to the scientific canons in so far as it usefully summarises many happenings and does not clash with anything in the general body of human knowledge, allows us to regard the water diviner as possessed of information and powers of deduction which he unwittingly applies in producing movements of the rod, just as the hysteric will, under the influence of motives not fully conscious, produce muscular movements or paralyses which he declares to be independent of volition. Whilst it does not involve the accusation of conscious fraud, this explanation denies to the diviner any knowledge that he could not attain by the exercise of his ordinary senses. Prof. Gregory describes many tests in which such knowledge failed to manifest itself. It is freely admitted that water is often found by sinking where the rod has given indications of its presence, but for obvious reaso negative findings are rarely tested, and he giv examples where only the hits were counted. T diviner is often ludicrously astray when he is test over areas where the distribution of water is accurate known. Diviners who claimed to detect undergrou oil were tested at the research station of the Angl Persian Oil Company and their results accorded wi rather unlucky guesswork. Prof. Gregory fears th it may seem disrespectful to those who believe in t divining rod to compare it with such an obsole habit as witch-hunting, but he remarks that t human mind in all people and amongst all ages h many features in common and is greatly influenced coincidences and unexplained phenomena. If wat divining really has such close affinities with witchcra and fetish as he believes the widespread trust in t method is rather disconcerting in a scientific age.

PROF. PIRQUET'S VISIT.

THE visit to London of Clemens Freiherr von Pirqu has given the medical profession an opportunity f attaching more personal characteristics to the epony of a tuberculin reaction and the originator of a wor wide system of dieting children. There are son apparently, who are unaware of an intervening peri in Dr. Pirquet's career, when he occupied the ch of pediatrics at Johns Hopkins University and infus an element of freshness into child study in Ameri Dr. Pirquet (as he prefers to be called) has recen been elected president of the "Save the Childre International Union at Geneva, and in this capac he addressed, while in London, a large gathering supporters of this Fund. He gracefully acknowledg the help given by this country to the children Vienna during the famine years, and attribut directly to this foreign help the fact that Vie itself is now doing more for its children than e before. Timely help in the crisis of their infancy l brought the children back to an almost normal st of health. Rickets, then extraordinarily preval in Austria, seems likely to disappear there entir within the next few years, and Dr. Pirquet is optim enough to believe that the same may be true tuberculosis in a quarter of a century. Sum diarrhœa among children, he said, was also d appearing in many countries; only in France the disease still rife, not because the French h child-life in any less esteem than we do, but beca of the prevailing custom to send the children i the country during the summer, where they dr unsupervised milk. He put in a plea for regard the common cold as highly infectious to infa many of whom, he thought, died from pneumo arising from a simple cold in the head. His fi remark, that possibly not more than 2 per cent. infantile deaths are unpreventable, was coup with the practical suggestion to concentrate on distr where a specially high mortality is recorded.

TREATMENT OF HICCUP WITH CARBON DIOXIDE.

IN a recent paper [1] Dr. R. F. Sheldon discusses treatment of hiccup by the inhalation of car dioxide. Hiccup is a spasmodic contraction of diaphragm, and its cause is probably abnor stimulation of the respiratory centre, either dire or through afferent fibres in the phrenic nerve. stimulus to the centre which produces nor breathing is an increase in the tension of car dioxide in the blood, and 5 per cent. of CO_2 in inspired air is more effective than anything else increasing the depth and strength of respiration. W this maximal stimulus it is reasonable to suppose t abnormal or lesser stimuli causing hiccup will ineffective, and that respiration will be uninterrup In administering CO_2 for this purpose Dr. Shel used the Henderson-Coburn machine in hospital

[1] THE LANCET, 1927, i., 718, 1037, and 1266.

[1] Jour. Amer. Med. Assoc., Oct. 1st, p. 1118.

ıe Gwathmey anæsthesia apparatus (Seattle model) h's private practice; both of them show the pproximate percentage of CO_2 in the air given. He escribes 11 cases. In seven of them hiccup came on fter a laparotomy; in one it followed an operation for bdominal hernia; in two it occurred during and after as-and-oxygen anæsthesia; whilst the remaining ase was one of the epidemic type. Carbon dioxide as inhaled for periods of from 1 to 20 minutes, eing breathed until the hiccup was controlled, which as usually within two to five minutes. Inhalation as resumed if hiccup returned, and the plan was to o on with the administration of CO_2 till there was o further recurrence. Success is reported in 10 out of cases. Most of the patients welcomed the treatment it produced no discomfort, although in one case halations were given regularly for five days (the eatest number in a day being 36), after which the ccup ceased permanently. Unfortunately the CO_2 uses an increase in blood pressure and respiratory fort and some exhaustion, so that Dr. Sheldon nnot advise its use for very debilitated patients. ieoretically, too, it may increase the chances of emorrhage after abdominal operations, especially ıen the stomach and gall-bladder are involved; but this respect the sudden contraction of the aphragm in hiccup is probably more dangerous than ep breathing. In order to control hiccup during æsthesia carbon dioxide may be given by the simple ocess of making the patient rebreathe his expired air.

ORTHOPÆDIC TREATMENT IN LONDON.

ORTHOPÆDIC surgery became prominent in the ddle of the nineteenth century because such erations as tenotomy and osteotomy were relatively e in pre-antiseptic days, and because the correction deformities could be largely carried out by chanical and non-operative means. When anti- otic and aseptic principles had reduced the dangers every kind of operation, the keen surgeon was awn to other lines of work, so that many of those o practised orthopædics were old-fashioned, relying ll on the simpler operations and on mechanical thods and failing to follow the more progressive nd of modern surgery. It is only comparatively ently that this important branch of treatment has ne back into its own.

In 1909, when the Royal National Orthopædic spital built its out-patient department, the new ommodation seemed to allow room for con- erable expansion. It was not expected that within years the hospital's work would increase more n fourfold and that considerable extension would ain be needed. The increase in work has not been e simply to an increase in the number of cases of same class as came to the hospital 25 years ago, t rather to an enlarged view of what constitutes a e suitable for treatment, and to a recognition of fact that the orthopædic surgeon, if he is a com- ent operator, is the right person to deal with most the surgery of the limbs, including the disabilities ulting from injuries. The new department, whose ening by the Lord Mayor we report on p. 1158, s long been under consideration, though the plans l building were delayed first by the war and then lack of money. Besides a handsome waiting-hall, sets of consulting rooms with operating theatre l plaster room, and ample offices for the almoners, contains large and well-equipped workshops which ble the hospital to make not only its own surgical liances for individual patients but also the various ints and frames, used as mechanical aids to treat- nt. The old out-patient department has been verted for use for massage and electrical and er forms of physical treatment, and there is a ge new radiographic department and photographic dio, besides fresh quarters for the resident staff, ich were badly needed. The in-patient department the hospital has also long proved inadequate, but ne years ago a decision was wisely made that no ension of in-patient work should be made on the Great Portland-street site. A small country branch had been established at Brockley Hill, Stanmore, only 10 miles from the parent hospital. Fortunately, a very large area around this has been purchased by the hospital, and simultaneously with the building of the new out-patient block a start has been made in building an entirely new country hospital on this site. So far an operating block, consisting of well-equipped theatres with two adjoining wards to house the patients before and after operation, has been completed, as well as one large, open-air block, and a building for kitchen and administrative purposes. It is proposed that additional open-air blocks shall be built as they are required and as financial conditions permit.

The Lord Mayor, in his opening address, called attention to the importance of extending orthopædic work to the treatment of adult cripples, and particularly of those suffering from industrial accidents and chronic disabling disorders of the joints. In the work of the hospital these branches of work are becoming more and more important. As the general organisation for the care of crippling conditions in childhood improves throughout the country, the children are treated earlier and more satisfactorily and require on the whole less in-patient accommodation, although the treatment of tuberculous disease of the joints still necessitates the upkeep of a large number of beds at the country branch. It is to be hoped that these extensions of in-patient accommodation will in the future enable the hospital to take more and more of the adult cripples besides carrying out the work that it has already done in the past for children. Heavy expenditure has been involved and, although Prince Henry was able to announce at the opening ceremony that the new out-patient department is paid for, the buildings at Brockley Hill are not in the same happy position, and a debt of £40,000 will remain outstanding upon these, unless it can be met by additional gifts.

WE regret to announce the death of Mr. Richard Anglin Whitelocke, lecturer on surgery at the University of Oxford, which occurred on Saturday last, Nov. 19th, in his sixty-seventh year. Mr. Whitelocke had been in bad health for some time.

THE King has approved the appointment of Sir Farquhar Buzzard to be Regius Professor of Physic in the University of Oxford in succession to Sir Archibald Garrod, who will shortly retire. Sir Farquhar Buzzard is physician to St. Thomas's Hospital and has been Physician Extraordinary to the King since 1923. He was created a Knight Commander of the Victorian Order at the beginning of this year.

EXETER ORTHOPÆDIC HOSPITAL.—The Duchess of York last week opened an orthopædic hospital for Devon and Exeter in the capital city of the county, which has been erected at a cost of £25,000, and dedicated a "Princess Elizabeth Cot" subscribed for by women and girls. The operating theatre block has been presented and equipped by the Rotary Club of Exeter.

WEMBLEY HOSPITAL STAFF.—The following have been appointed to the consulting staff of the new Wembley Hospital, which will be opened in the New Year: honorary consulting physicians, Sir John Rose Bradford and Dr. C. E. Goddard; consulting physicians, Dr. Batty Shaw and Dr. Norman Hill; consulting surgeons, Mr. E. K. Martin and Mr. P. H. Mitchiner; consulting surgeons for the diseases of women, Dr. J. W. Bell and Dr. Gertrude Dearnley; consulting surgeon for diseases of the eye, Mr. R. C. Davenport; consulting surgeon for diseases of the throat, nose and ear, Mr. Douglas Robertson; consulting physician for diseases of the skin, Dr. A. C. Roxburgh; consulting anæsthetists, Mr. A. F. Potter and Mr. H. N. Webber; consulting pathologist, Dr. H. A. Osborn. The consulting radiologist has not yet been appointed. The local staff will comprise the whole of the medical practitioners of the Wembley area.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLI.

THE TREATMENT OF SEA-SICKNESS.

THERE is a well-marked variation in liability to sea-sickness shown by different age-groups, sex-groups, and individuals. Infants under 1 year of both sexes are practically immune from this complaint, possibly owing to the non-development of their sense of balance. An adult could never experience with impunity the tossings and rockings a baby has to endure. Old people of both sexes are also practically immune. The athletic type in whom powers of oxidation are well developed suffer very little; heavy and even moderate drinkers who have acquired the habit of quickly oxidising carbohydrates also belong to this class. On the other hand, the hypoglycæmic diathesis is a direct predisposing cause. This group includes children liable to *cyclic vomiting*, certain types of *endocrine dysfunction*, sufferers from *migraine*, and those liable to ketosis from slight causes. *Pregnancy*, in which there already exists a disturbance in metabolism, causes excessive sea-sickness. Nephritis, with its diminished blood carbonate reserve, and diabetes with pre-existing ketosis are also predisposing causes. The well-known type of person who vomits before the ship sails again comes under a different category, and requires different treatment. Such a case should be treated by reassurance, and if very agitated a sedative such as pot. brom. gr. xx. is useful.

Differential Diagnoses.

Sea-sickness is liable to occur with, and to obscure, certain much more serious conditions, and it is imperative to ascertain that no grave underlying disease is present. The condition most commonly met, and one which may cause great difficulty in the differential diagnosis, is *acute appendicitis*. This may mimic sea-sickness very closely; vomiting, abdominal pain, and headache may be complained of in either case. The abdominal pain in sea-sickness, however, does not cause rigidity, there is no rise in temperature, but rather the reverse, and an hourly pulse and temperature chart will make the diagnosis clear. *Acute intestinal obstruction* may be a complication of sea-sickness, since the act of vomiting may cause either obstruction by a band or incarceration in a hernial sac. The pain in obstruction is far more severe than that caused by sea-sickness, and once suspicion is aroused a careful abdominal examination and the administration of one or two enemata will leave no doubt as to whether obstruction exists. Perforations, especially of gastric ulcers, may be masked by sea-sickness; a perforation causes much more severe pain and shows those characteristic signs of rigidity and collapse which are pathognomonic of this catastrophe. There are medical conditions also liable to be overlooked, including the typhoid and paratyphoid fevers, and, especially when sailing in the East, small-pox. These possibilities have been stressed because the patient invariably attributes all his symptoms to sea-sickness and may mislead his physician unless the latter always keeps the graver diseases in his mind.

The Breaking of a Vicious Circle.

When other diseases have been excluded and the type of case being dealt with has been ascertained, the treatment of sea-sickness resolves into the breaking of a vicious circle.[1] Whatever the cause of the initial vomiting, whether nervous, due to labyrinthine stimulation, irritation of the splanchnic sympathetic, gastric irritation, or ketosis following hypoglycæmia, the persistent vomiting combined with the absence of food soon causes a ketosis. It is vital, therefore, to administer carbohydrate to the patient, and the easiest and pleasantest way is to give orangeade made with glucose (glucose, one tablespoonful, one squeezed orange to one tumbler of water with ice). This is absorbed directly from the stomach, and if it is only retained a few minutes some is absorbed. The patient should be encouraged to sip a little of this drink as often as he likes and very soon the worst feelings will pass away. Diminished urinary excretion is a marked feature in sea-sickness, the urine giving a considerable deposit of urates on standing; if the kidneys are not very active they are unable to excrete this concentrated urine and waste products accumulate in the blood; this is another good reason for encouraging the consumption of fluids.

Drug Therapy.

Combined with the administration of fluids and glucose, various drugs which have been recommended from time to time may be tried. The list includes atropine, tr. belladonnæ, cocaine, sodæ bic., chloretone, pot. brom., morphia, hyoscyamus, acid. hydrocyan. dil., cerium oxalate, tr. iodi, bismuth and soda, sodamint tablets, mothersil, seoxyl, and many others. None is specific, but some are helpful under different circumstances. Pot. brom. gr. xx., combined with tr. belladonna ℥ v., is useful in nervous patients, especially in those suffering from insomnia. Belladonna is given with a view to inhibiting the motor effect of the vagus on the stomach. On the same principle atropine may be administered combined with strychnine (atropine gr. 1/100, strychnine gr. 1/30) hypodermically when a patient shows signs of collapse. Chloretone has its advocates. This drug is a gastric sedative and cerebral depressant, and is also suitable for the nervous case. It is given in cachet form in doses of gr. v. not more often than twice a day; generally it is absorbed with difficulty, but it may be absorbed in massive doses should it accumulate in the presence of fatty acids in the bowel. Chloral and bromide may be given per rectum in cases where nothing can be retained by mouth, in the form of a suppository containing chloral hydrate gr. xv. and pot. brom. gr. xxx., three times a day. Morphia may be given hypodermically, but its use very rarely needed if the other remedies are used with discretion. A useful routine mixture consists of two powders: (*a*) pot. bic., gr. xv.; (*b*) citric acid, gr. x.; glucose, ʒ iv. When dissolved in water and mixed these give a palatable effervescent drink which often cuts short an attack. In very bad cases where nothing can be retained by mouth, and where collapse is threatening or present, glucose should be administered with saline per rectum, or better 6 per cent. glucose. This solution should be given in 15-oz. doses every four hours, and is nutritive as well as useful in replacing lost fluid.

Diet and Management.

The patient should be kept warm, and the air fresh. This is very important as oxygen scarcity is a direct precursor of ketosis. Part of the increase in sea-sickness observable during storms is due to the necessity of shutting the portholes with a consequent diminution of oxygen-supply. Stewardesses have a habit of advocating a chair on deck as a curative measure; this is not advisable in a cold wind after an attack of sea-sickness, and the recumbent position should be maintained until two meals have been digested. In some cases closure of the eyes affords relief. All causes of emotional disturbance should be avoided, and it is therefore wise to have a receptacle, in a convenient position, for the early stages of the voyage, as this will allay fears rather than encourage its use. As soon as the patient begins to improve light food should be taken. Patients exhibit individual preferences, but chicken sandwiches without butter, biltong spread on dry toast, fruit. jellies, be f-tea are usually acceptable. Tea and coffee with milk are usually badly tolerated, but iced weak tea with lemon and sugar is beneficial. Dry ginger ale, with or without brandy, and cha-

[1] THE LANCET, Oct. 15th, p. 811.

agne have their supporters. It is wise to recommend he patient to avoid all fats, but otherwise to take lenty of food even if it is not all retained.

Complications.

Apart from the acute surgical emergencies which ay arise either along with or due to sea-sickness, here are sequelæ which require treatment. *Constipa-ion* is a common complaint which is due to the hange of diet and mode of life. An effervescent aline aperient given before breakfast is very useful, eidlitz powder being especially so, as it is laxative, ffervescent, and alkalising. If these do not agree he aperient habitually taken by the patient should e allowed.

Diarrhœa often accompanies severe sea-sickness. he exact cause of this is uncertain, but it is possibly ue to a pancreatic disturbance. It may be very oublesome but passes away as vomiting lessens.

Cystitis.—True cystitis does not occur as a sequela f sea-sickness, but a condition resembling it clinically frequently seen. It is due to the unusual con-ntration of the urine and not to microbial infection. A few doses of the following mixture will soon alleviate the condition: pot. cit. gr. xx., tr. hyoscyam. ℥ xx., inf. buchu co. ad. ℥ ss., t.d.s. This treatment is preferable to the giving of acid sodium phosphate and hexamine since the urine is usually very acid already; the condition is not an infection, and tends to clear up when the urine is rendered more alkaline.

Headache.—If there is no acetone in the urine the headache should be treated on ordinary lines by the exhibition of aspirin gr. x., phenacetin with caffein gr. x., &c.; the presence of acetone in the urine is a sign that more glucose is required.

Short Voyages.

For short journeys a rather different method of treatment is required. Poor sailors should partake of a good meal two hours before embarkation, and take chloral gr. v. or pot. brom. gr. x. to xv. Immediately on embarkation the dose should be repeated and the patient should lie down. In this way a short journey may often be passed in comfort.

G. H. ORIEL, M.D. Camb.,
late Surgeon, Canadian Pacific Steamships.

GENERAL MEDICAL COUNCIL.

PRESIDENT'S ADDRESS.

THE 126th session of the General Council of Medical ducation and Registration opened on Nov. 22nd th the customary address by the President, Sir ONALD MACALISTER. He began with sympathetic ference to the death since the last session of the uncil of Prof. Harvey Littlejohn, of Edinburgh, d Mr. Thelwall Thomas, of Liverpool, whose places d been filled by Prof. J. Lorrain Smith and Mr. W. Monsarrat. Another change in the member-ip of the Council was occasioned by the appoint-nt by Manchester University of Prof. J. S. B. opford to succeed Prof. R. B. Wild. The Queen's niversity of Belfast had sent Prof. R. J. Johnstone, P., in succession to Colonel Sinclair, M.P., who ained his seat on the Council in another capacity Crown nominee. The President continued:—

Registration in the Irish Free State.

"Four members of our body have been appointed the Irish Free State Medical Registration Council, ablished under the Free State Act, passed in cordance with the recent agreement to which I de reference in my last address. The election of colleague Dr. Coffey as President of the Irish uncil goes far to ensure its smooth and effective rking, in coöperation with our own body. The itish Bill for the ratification of the Irish Agreement s passed through the House of Lords. It is expected come before the House of Commons during the sent session of Parliament.

Pharmaceutics.

"The committee considering the question of the thod of preparing the next British Pharmacopœia s practically completed the taking of evidence, d will, I learn, proceed forthwith to the drafting its report. But I shall have no fresh information the subject to communicate to the Council at the sent session. We are still awaiting the conclusions the Privy Council Committee on the Poisons and rmacy Acts. These conclusions may have bearings medicine, which will call for your consideration a later date.

The Colonial List.

"The Executive Committee has had communica-ns, through the Privy Council, from Quebec, tario, and New Zealand, which indicate a disposi-n in these parts of the Empire to withdraw from ctitioners registered in the Medical Register the privileges of practising within their respective territories which have hitherto been accorded them, in virtue of reciprocal agreements made by Order in Council. The ground for the withdrawal seems, generally speaking, to be a desire to 'protect' certain local professional interests. If no modification of the views held by the provincial authorities on this subject can be brought about, the Privy Council will have to consider whether the privileges granted by this country to practitioners from these British possessions now registrable on the Colonial List of the Register can justly be continued.

Indian Standards.

"The reports of the Executive Committee, based on the results of the visitations and inspections of Sir Norman Walker and Colonel Needham, have been duly forwarded to the Secretary of State for India, the Indian Government, and the Indian Universities. There has as yet been time for little more than formal acknowledgments of their receipt; but from numerous unofficial communications we may gather that the desire of the Council to assist the Indian authorities in their efforts to improve the methods and standards of medical education in India has been gratefully recognised. We further learn that definite steps have been taken to bring before the Central Legislature the question of establishing, by the agency of an all-Indian Council, some form of control of Indian standards of professional qualification. It is of interest in this connexion to record that both Sir Norman Walker and Colonel Needham have been severally invited to visit the United States, within the next few months, for the purpose of giving to certain medical authorities in that country the benefit of their special experience in matters of medical education and examination.

Medical Education.

"The Education Committee will probably be able to present to you at this session a final report, setting forth the progress made by the several teaching and examining bodies in this country towards giving legislative effect to the Council's resolutions on the medical curriculum, which came into force in January, 1923. It is satisfactory to observe that, almost without exception, the regulations of the licensing bodies are now in practical conformity with the principles laid down by the Council. The circulation of the final report among the bodies concerned will without question be of service to the cause of professional training and testing. Each body will find something of value for its own use in the experience and practice of the others. The Examination Committee, in like manner, will have a report to submit on the visitations of professional examinations other than the final or qualifying examination. From this report also much may be learned regarding the merits

of diverse examinational methods and arrangements. The regulations for the registration of medical and dental students have been carefully revised by the Education Committee, with a view to greater clearness and consistency in their statement. The amended form will be submitted for your approval."

In conclusion, the President stated that in company with Mr. Eason he had appeared before the Departmental Committee on the Registration of Opticians Bill, and given evidence in support of the memorandum on the subject which appears in the Council's Minutes. So far as he was aware the decision of the committee had not yet been published.

Sir HOLBURT WARING proposed, and Sir NORMAN WALKER seconded, a vote of thanks to the President for his address. The following appointments were officially notified: (*a*) Mr. Robert James Johnstone, representative of Queen's University, Belfast, for three years from June 15th. (*b*) Dr. John Sebastian Bach Stopford, representative of Manchester University for three years from Oct. 22nd. (*c*) Dr. James Lorrain Smith, representative of Edinburgh University for five years from Oct. 24th. (*d*) Mr. Keith Waldegrave Monsarrat, representative of the University o Liverpool, until Dec. 31st, 1930.

The Council then considered penal cases.

MEDICINE AND THE LAW.

Unsuccessful Claim for Negligence.

Dr. J. M. Todesco, resident medical superintendent of the Croydon Borough Isolation Hospital, and Dr. J. Elder, formerly assistant medical officer at the hospital, are to be congratulated upon the failure of the protracted proceedings initiated against them by Mrs. Venn. The plaintiff, who claimed damages for the death of her husband (in June, 1922) on the ground of the alleged negligence of the two defendants, had made three attempts. The case first came before the Lord Chief Justice in June, 1925; it lasted five days, and ended in the disagreement of the jury. It next came before Mr. Justice McCardie in February, 1926, when it went on for eight days with the same result. It finally was tried before Mr. Justice Horridge from Nov. 11th to 17th, and ended in a verdict for the defendants. The learned judge, at the beginning of the recent trial, explained to the special jury that the claim was brought by the plaintiff under the Poor Persons Rules; this meant that her solicitors and counsel would get no fees, and the same fate, it appears, befell the jurymen. The history of this case seems to suggest that a "poor person" can indulge in litigation which otherwise only a very rich person could afford. If the jury had continued to disagree, Mrs. Venn might have continued indefinitely to occupy the courts to the exclusion of other litigants. Meanwhile, the unfortunate defendants, against whose professional reputation her attack has failed, have no prospect whatever of being refunded one penny of the heavy costs which her three years of litigation have imposed upon them.

Legitimacy Act Applications.

Although applications under the Adoption of the Children Act are heard in camera, both in summary proceedings before magistrates and in the county courts, no such encouragement is given to applicants under the Legitimacy Act. Under the latter Act, it will be remembered, an illegitimate child of parents who afterwards marry can claim a declaration of legitimacy if the parents were in a position to marry when he was born. It would seem at first sight that proceedings under the Adoption of Children Act and under the Legitimacy Act are alike in demanding protection from publicity and curiosity. But the Attorney-General, who is a party to all proceedings under the Legitimacy Act, has refused to agree to their being disposed of in private. It was laid down in Scott *v.* Scott ([1913] A.C. 417) that His Majesty's courts must be open to the public, and that publicity is necessary to the proper administration of justice. Exception is made only where publicity would prevent the proper administration of justice, as, for instanc on an injunction to prevent the exploitation of secret process or where particular evidence could n be given in open court. In Scott *v.* Scott Lo Halsbury declared that a mere desire to consid feelings of delicacy, or to exclude from public heari details which it would not be desirable to publis is not enough to prevent a public hearing. In recent case under the Legitimacy Act of 1926— case described as the first petition to be present under the Act—Lord Merrivale adopted Lo Halsbury's language and said that it was not the l that, if publicity deterred a person from taki proceedings, he should therefore be allowed to bri his case in camera.

There was a strange flaw in the drafting of t Legitimacy Act, 1926. The procedure under t Legitimacy Declaration Act of 1858 was appli without it being noticed that the 1858 Act had be almost entirely repealed and superseded by t Supreme Court of Judicature (Consolidation) Act 1925. This error was pointed out in a case report in the *Times* of June 22nd, but appears not to fatal. The main task before the applicant for legitimacy declaration is to prove his facts and ensure that all interested persons should be brou before the court, including possibly the next-of-k of the putative father. Where there are two three brothers and sisters who are making an applic tion upon the same set of facts, one set of affidav and one body of evidence will apparently be accept by the court on behalf of all the applicants. It m be added that, though proceedings cannot be heard camera, reputable newspapers may well decide r to publish the names of the parties.

Preservatives in Food.

As is well known, the Public Health (Preservativ &c., in Food) Regulations of 1925, amended in 19 and brought into operation at the beginning of 19 prohibit the use of boric acid and impose conditio upon the employment of permitted preservativ They provide, for instance, that sausages or sausa meat may contain preservative in the form of sulph dioxide in the proportion of 450 parts per milli Sausages or sausage meat, if containing preservati must be labelled to that effect, and articles sold a preservative are to bear the label "This preservati contains — per cent. of sulphur dioxide." The *Tim* of Nov. 16th records two prosecutions under the provisions. In one a firm of manufacturing chemi at Southall was fined £42, and ordered to pay £5 costs, at Brentford police-court for selling preservat which was labelled and warranted to contain 7 cent. of sulphur dioxide, whereas on analysis 11 per cent. was found present. It was stated that preservative powder was retailed to several butch who had been summoned and fined for using m than 7 per cent. sulphur dioxide in sausages. T defendant firm stated that the consignment, af being prepared, got wet, and that the constitu parts must have changed in the redrying proce The other prosecution on the same day was at Guildhall, where a West Smithfield company w summoned for selling preservative powder sausages which contained 0·3 per cent. boric a contrary to the Regulations. It was pointed out behalf of the defendants that this amount was trifl compared with what was permitted before the rec Regulations came into force. The Alderman, w heard the summons, refused to accept this as defence, though he inflicted only a small fin 20*s.* and a guinea costs. It is undoubtedly hard u defendants who buy in bulk and sell in retail u the faith of a manufacturer's false description. T defendant company, it was stated at the Guildh merely put up in tins the powder which they bou from a well-known firm. It was suggested that t company had done all it could reasonably be expec to do. The Alderman, however, remarked that could have analysed the powder as had been d by the prosecution.

ROYAL SOCIETY OF MEDICINE.

ANNUAL DINNER.

THE annual dinner, held at the Hotel Victoria
1 Nov. 16th, was well attended and made memorable
7 the presentation of a presidential badge, bearing
e new coat of arms already described in our columns.[1]
r JAMES BERRY presided, and the guest of the
ening was Lord Darling, who, in proposing the
alth of the Society, pointed out how his profession
d worked for the preservation of medical privilege,
rticularly by discouraging the administration of
senic and strychnine and the performance of
acheotomy by unqualified persons.

Sir STCLAIR THOMSON described the origin and
pearance of the new badge, of which he was the
nor. St. Cosmas and St. Damian had started their
reer, he said, as Arabian physicians, who resembled
eir modern successors in their title of "Anargyres"
oneyless) and their aspiration to sanctity. They
ffered persecution under Diocletian, but neither
prisonment, beating, nor stoning broke their spirit.
nally they were bound and thrown into the sea,
d there was a mural painting by Fra Angelico
picting an angel helping them ashore—"in the
esence of two witnesses," Sir StClair Thomson
ly added. Cosmas and Damian became patron
nts of the great Medici family, and as such appeared
mosaic, painting, and sculpture by the greatest
ists of Italy. They had, therefore, a strong claim
be the supporters of the coat of arms. The motto
the old Royal Medical and Chirurgical Society,
Non est vivere sed valere vita," had been retained.
meant (he hoped) "We're all alive and having a
od time." Giving of one's own out of love and
lowship was to him the salt of life, and in that spirit
begged the President to accept the chain, badge,
d coat-of-arms.

Sir JAMES BERRY, in acknowledging the toast,
d a letter from Sir William Church, first president
the amalgamated societies, written within a day
two of his ninetieth birthday. He reviewed the
r's progress. There had been an increase of
20 per cent. in the services rendered by the various
partments of the library, and the "Proceedings"
d been greatly improved. The number of Fellows
reased steadily, and an immense amount of valuable
rk had been performed by the sections. He thought,
wever, that more might be done by special scientific
mmittees in investigating questions of medical
ence. During the past year, for instance, a joint
mmittee of anæsthetists, surgeons, and pathologists
d been considering a matter referred to them by
Ministry of Health. The Society contrived to
y its way, but would be glad to be free of a debt
over £20,000 on the building.

Proposing the health of the guests and the kindred
ieties, Mr. WARREN LOW speculated on the origin
the custom of toasting the visitors. He liked to
nk that it was a signal that no further harm to
guests was intended than the speech. The Black
ner at Edinburgh Castle, and the meal to which
tain Roman bachelors had invited their neighbours,
Sabines, must have broken up shortly after the
al toast. He referred to the difficulties of the doctor
courts of justice, especially when called as "expert
ness," a term which he hoped would be judicially
demned as libellous; and when placed in the
ness-box to become the butt of judicial humour
l the victim of what was aptly called "cross"
mination.

Sir ARTHUR KEITH, replying for the guests, referred
the double personality of Barrie and McConachie,
l said that the President of the British Association
l enjoyed hospitality that evening, but that the
tleman replying to the toast was the humble
vant of a proud college. Adapting a remark of
Berkeley Moynihan's, he described himself as a
r medical practitioner who had been doomed to
practise anatomy, but had always kept his foot in the door of medical practice. He spoke earnestly of the rationalisation of medicine, but there were two great hindrances: the first was the difficulty of coming to a final conclusion as to the proper thing to do; the second, and greater, was to educate the public. There would never be a rational medicine until the public had been educated. If we were rational, a Harley-street address and the doctor's clothes would mean nothing to us. The hospitals sent out young men resolved that, as far as in them lay, they would not be quacks in any sense of the term, that they would be rational; but they did not know what they were up against. It was the public that kept science back. Those who desired to make progress should not look on the human body as a duality, but as a unity.

Among the guests were the Presidents of the kindred societies; the Master of the Society of Apothecaries; Mr. Martin Travers, the designer of the coat-of-arms; Prof. Pirquet, of Vienna; and Mr. and Mrs. Geoffrey Duveen.

[1] Nov. 12th, p. 1036.

BRITISH INSTITUTE OF RADIOLOGY AND THE RONTGEN SOCIETY.

THE inaugural dinner to celebrate the amalgamation of the Institute with the Society was held at the Hotel Great Central, London, on Friday last, Nov. 18th. The dinner was followed by some good and interesting speaking.

The toast of the Amalgamated Societies was proposed by Sir FRANK DYSON, the Astronomer Royal, who humorously contracted out of any necessity for making intimate references to either body, because, while he appreciated the importance of the wedding, he was unacquainted with the exact character of either bride or bridegroom. The Astronomer Royal described graphically the sensation which had been caused by Rontgen's discovery over 30 years ago and which vied with excitement caused by the exploit of Mr. Blériot in flying the English Channel 14 years later; each was an unmistakable demonstration of the march of science. He dwelt upon the suggestive fact that Rontgen to a certain extent had made his discovery accidentally, or rather incidentally, while working at other high problems in physics, but the influence which that discovery had had upon medicine was of a fundamental nature. No doubt, said Sir Frank Dyson, doctors, with vast material for observation and trial, would have discovered much in the location of foreign bodies by elaborately devised employment of probing and perfection of other methods, but medicine saw at once the great field of diagnosis that had been opened up, and was quick off the mark to annex it. He pointed to the development of radiology as instanced by the fact that shortly after Rontgen's discovery the popular exhibition of its surgical and medical significance was to give the guest at a scientific soirée an opportunity of seeing his own skeleton, while to-day a radiological exhibition was a highly standardised and technical affair. He said that from personal knowledge he had been much struck by the shortness of the exposures necessary to arrive at a diagnosis, while the safety of the procedures had also impressed him; and he evidently thought that the attendant at a radiological clinic, who showed the adjacent mortuary to a patient proceeding to the diagnosis chamber, had been unduly cynical. Speaking generally of the advantage of the amalgamation of the bodies working at radiology, he pointed out that the separation of different sections of a common branch of learning was always unfortunate. He would distinctly dislike the science of astronomy to be approached along two different lines of theoretical astronomy and astral physics; in the study of X rays, as in astronomy, the sciences must be ready to receive all advantages, from whatever branch of physics they may be derived.

Sir HUMPHRY ROLLESTON, in reply to the toast, endorsed the Astronomer Royal's plea for union and coöperation in science, pointing out that those who devoted themselves to radiology might otherwise be in danger of getting segregated in their own departments. It is not good, he said, for man to live apart; and if the marriage which they were now celebrating was to be profitable it must not be regarded as a Darby and Joan existence. Rather in this union they had projected a life of increasing activities and especially of thought for offspring, for they intended to found branches in the provinces to be affiliated with the central institute. The previous monthly meetings of the societies would not be given up, and the instruction for the diploma in medical radiology and electrology would be continued, while strong sections of physics and radiology in application to medicine would be active in medical societies. In allusion to the work done by the Rontgen Society in bringing about the affiliation he alluded specially to the President, Dr. Finzi, of whom it might be said that, whichever body was bridegroom and whichever bride, he was the best man. In allusion to the guests present, he pointed out that Sir John Rose Bradford, in his position of President of the Royal College of Physicians of London, was seldom allowed to dine at home, sacrificing the advantages of domestic union for the good of the general union of medical forces. He welcomed the presence among them of Prof. Wachtel, of the Radiological Institute at Cracow, and of Dr. Knox, fortunately recovered from recent illness. In conclusion he announced that the firm of Messrs. Watson and Sons had sent to the Amalgamated Bodies a donation of 100 guineas as a wedding present.

The toast of the guests was proposed by Dr. THURSTAN HOLLAND, who coupled with it the names of the President of the Royal College of Physicians, and Mr. E. H. Rayner, D.Sc., of the electricity department of the National Physical Laboratory.

Sir JOHN ROSE BRADFORD, in reply, categorically refused to speak for anyone like the Astronomer Royal. He was prepared, he said, to deal with matters terrestrial, but Sir Frank Dyson was immersed in matters celestial, while, judging from what occurred at the recent total eclipse in England, he could command the sun to behave in the way best suited to illustrate for himself the expected phenomena. He thanked the Society not only for their hospitality, but for giving him sound moral advice as to the cultivation of domestic instincts, and added that he did not think the company would expect him to expatiate upon the benefits derived by medicine from radiology—they were so obvious.

Dr. RAYNER spoke eloquently of future developments of radiology viewed from the aspect of physics. He claimed scientific descent from his grandfather and his father, and he welcomed the opportunity at the National Physical Laboratory for assisting the development of radiology in the cause of medicine, a development of which he spoke in eloquent terms. He proposed that the guests at this inaugural dinner of the amalgamated bodies should send a message of greeting to Prof. Coolidge, whose name was ever on their lips, as his tubes were ever in their hands.

The health of the President was proposed by Mr. G. W. C. KAYE, D.Sc., superintendent of the Physics Department of the National Physical Laboratory, who said that, from the moment the necessary fusion of the two became imminent, it was felt that there could only be one captain for the ship—namely, he who, from the position of a physician, had done more than any one man for the cause of radiology, and whose management of their affairs had throughout been conducted in so courteous and competent a manner.

Sir HUMPHRY ROLLESTON, in a brief reply, asked all present to join him in drinking the health of Dr. Stanley Melville, to whose efforts the entertainment they were enjoying was due, and mentioned in similar association the names of Dr. John Muir and Mr. Cuthbert Andrews.

Dr. STANLEY MELVILLE felt that he could not tak personal credit for what he believed had been a mos successful little congress, apart from his colleague Dr. Muir's capacity for strenuous work was we known to all the members of the Institute and neede no words from himself except to say that witho him all would have been chaos. Mr. Cuthbert Andrew had been a moving force in the organisation, f always he had given the impression that nothing wa too good for the business on hand, and even th Central Hall, Westminster, was all too small for wha he wanted. Dr. Melville concluded with an amusin suggestion for future festival dinners—namely, tha instead of formal orations the gathering should resol into a symposium, the speeches taking the form personal reminiscences. He instanced the pleasure would have given the company had their Presider discussed the value of the early morning game tennis, the Astronomer Royal his personal experienc during the last eclipse of the sun, and Dr. Finzi h Alpine climbs.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

THE following are some of the 1926 statistics four cities:—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rate per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Diarrhœa, &c., under 2 years.	Infant mortality.	Maternal mortality
Liverpool .. .. (849,593)	23·3	13·7	1·47	1·17	3·3	1·1	26·4	104	3
Manchester .. (761,320)	18·3	13·2	1·41	1·44	2·9	1·4	16·3	87	4
Sheffield .. .. (523,300)	17·2	11·3	0·93	1·19	2·1	1·4	13·6	79	6
Leeds .. .. .. (473,400)	17·0	12·8	1·24	1·39	2·3	1·6	18·2	93	3

The neonatal mortalities from above downwards were: 34, 37, and 39.

Liverpool.

Dr. A. A. Mussen reports that the infant mortalit rate was 104, as compared with 99 in the previc year, and that the increase is attributable to t prevalence of diarrhœa and enteritis in the cent parts of the city. An investigation of the cau again emphasised the importance of breast-feedi Two cases of plague were notified in August (report in THE LANCET, 1927, i., 870), but no evidence plague-infected rats was discovered. Immunisati against diphtheria has been carried out successfu in a number of institutions. In six of them th were 46 cases of diphtheria during the six mont before the inoculation, whereas there were only fo cases in the subsequent six months. An investigati has shown that in Liverpool 20 per cent. of t juvenile survivors from encephalitis lethargica ne institutional treatment. These "conduct" cases a often amenable to a kindly discipline, says J. Mussen, and to certify them all as moral imbeci under the Mental Deficiency Act or to place th among the insane appears to be unjustifiable, thou in a few cases this course may be desirable. Th is no special institution available in Liverpool, a the number of cases occurring in any particu district is too small to justify the establishment of o A general meeting of the larger municipalities w called together in November to consider the establi ment of a joint institution. Dr. Mussen says t

ne further decline in the deaths from alcoholism and infants from overlying affords "most eloquent stimony to the improved social condition of the ty."

The maternity and child welfare centres have en well attended. The births during the year mbered 19,792, and 1668 expectant mothers tended the four antenatal clinics under the control the Health Committee. Of these 412 were primi-avidæ and 1256 multiparæ. The Carnegie infant elfare centre has proved of great value. It pro-des clinics for infants and expectant mothers, ards for babies who are not thriving, and an educa-onal centre for students of preventive medicine.

The treatment of venereal diseases at the Seamen's spensary shows a marked growth; there were 1 new cases in the nine months of 1924 after the ening, 1084 cases in 1925, and 1360 in 1926. The tients are attentive to instructions and take an elligent interest in their progress. The tuber-losis scheme suffers badly from the lateness of tification.

Five cases of anthrax occurred; one of the patients ndled wool in a warehouse, another discharged les from a vessel, and a third was a "lime-jobber" a tannery. Two women were manipulating foreign hair at the time of infection. Of the five patients o died. Although the death-rate from respiratory eases was high, a table shows that it was nearly ice as high during the last three decades of the eteenth century. During 1926 eight cases of sentery were reported, in addition to three which ived on shipboard. Dysentery was formerly pre-ent in Liverpool, and Dr. Mussen thinks that some the deaths registered as from diarrhœa are really m dysentery. During the last 30 years there has n an apparent increase in the death-rate from betes, but it is suggested that the greater attention ently paid to this disease has led to its more quent recognition as a factor in mortality. About per cent. of the total births were attended by lwives, including 1471 by the midwives on the ff of the Ladies' Charity. As far as is known no hs were attended by uncertified women during year. Nearly 4 per cent. of the 347 stillbirths teriologically examined were found to be due to hilis. No damage to eyesight from ophthalmia natorum has occurred during the past two years. ty-one mothers with their infants were admitted St. Paul's Eye Hospital for the treatment of this ction.

About one-third of Liverpool's milk comes from 0 cows stalled in the city. Among these 20 tuber-ous udders were found during 1926. Among the side cows ten tuberculous udders were discovered. bacteriologist's report shows that out of 157 ples of milk supplied to the city hospitals 11 con-ed tubercle bacilli; that out of 81 samples sup-d to infant welfare centres six contained tubercle illi, and that out of 578 samples taken from milk ps, railway stations, &c., 38 contained tubercle illi.

The new houses built numbered 4838, of which 2 were municipal. This is a great advance on eding years. The replacement of insanitary ses in the centre has been begun in the Pitt-street a, where 57 tenements are now under construction.

Manchester.

Dr. R. Veitch Clark reports that the scheme of k initiated by the Manchester Committee on Cancer May, 1926, has proceeded actively. The main line research is the means of prevention of mule-ners' cancer. The effects of the various lubri-ng oils used in cotton-spinning are being studied. follow up of operation cases shows that 80 per . of cases of cancer of the breast were alive ten s after operation. A record is being kept of the ological examination of all tumours dealt with he Royal Infirmary. A post-graduate course of ectures for medical men on various aspects of the er problem has been held. The lectures will be published in book form and distributed to medical men in the neighbourhood.

In spite of continued municipal activity there is no real improvement noticeable in housing, but it is anticipated that the increased rate of building will have a recognisable effect within a reasonable time. Unfit houses cannot be dealt with at present. Three unhealthy areas have been scheduled, which include 1463 houses, but of these it has only been possible to deal with a small area containing 199 houses. The seriousness of the housing problem is emphasised in a special report on housing in relation to child-birth, in which an analysis has been made of the conditions under which 1000 confinements occurred in the working-class districts of Manchester. The outstanding fact revealed was that privacy was only possible in 46 per cent. of the houses occupied by one family and in 2 per cent. of the houses occupied by more than one family.

Since November, 1924, observations have been carried out as to the incidence of sunlight in Manchester as compared with the neighbouring districts of Timperley and Baguley, and since April, 1926, the available ultra-violet rays have been measured. During 1925 and 1926 Manchester only received 59 per cent. and 55 per cent. of the sunlight falling upon Timperley. The regional joint smoke committee is not yet in smooth waters. Very few of the constituent authorities favour the establishment of a united district, and the effort is being made to bring about instead some uniformity of procedure among the various authorities. The reorganisation of the inspectorate which took place at the end of 1925 has proceeded smoothly and realised a large and permanent economy. A large number of special inspectors have been drafted into district work and the staff of disinfectors has been abolished.

At Baguley Sanatorium tuberculin has been used in the diagnosis of doubtful cases, and it is claimed that this procedure has been "of value in eliminating a number of cases that might have been designated pulmonary tuberculosis for the rest of their lives." At Monsall Hospital the treatment of puerperal fever on the lines recommended by the Medical Research Council has been continued. The main lines have been lymph drainage of the uterus, blood transfusion, and the use of arsenical drugs. During 1926 defibrinated blood transfusion was discontinued owing to disappointing results, but a reliable apparatus for whole blood transfusion has now been obtained. In certain cases arsenical drugs have done good. The admixture of iodine with the glycerine used for the local treatment has been persisted in, despite its discontinuation elsewhere. The absence of complications has again been a marked feature of the glycerine-iodine irrigation. Other interesting work carried out at Monsall in connexion with the Dick and Schick tests is described in the report. Of the 474 samples of outside milk examined 49, or 10·3 per cent., proved to be tuberculous. Colonel Brittlebank, the chief veterinary officer, says the increase in tuberculous milk is due in some part to the increased area of supervision, "but it also clearly points to the fact that the Tuberculosis Order, limited in scope as it is, and administered very often in the unsatisfactory manner that it is, provides no protection against infection in the general milk-supply." Nothing is being done, he says, to encourage early notification, and although the discovery of tuberculous milk is generally evidence of widespread infection on a farm, the veterinary surgeon is frequently prohibited from examining all the animals in the herd, and is restricted to dealing with the case notified.

The services of experienced obstetricians have been made available under the puerperal fever scheme. Dr. Clark stresses the fact that puerperal fever shows no tendency to get less, that it is frequently associated with difficulties in labour which call for "an extension of our markedly inadequate antenatal work," and that other needs for its prevention are "more maternity hospital accommodation and more housing."

Sheffield.

Prof. F. E. Wynne says that the most important public health event of the year was the outbreak of small-pox. There have been a few cases in Sheffield in each year since 1921, but the disease did not gain any footing until the last quarter of 1925, when there were 44 cases. Special arrangements were then made by the equipment of the hutment camp at Redmires. During the early part of 1926 the disease seemed to be under control. The notifications in the first four months were 9, 3, 7, and 12 respectively. In May, June, and July the notifications numbered 1, 1, and 3, and then the prevalence began to increase, as there were 6, 13, 19, 31, and 52 notifications during the five months August to December. Dr. Wynne suggests that the rise towards the end of the year coincided with the reopening of the elementary schools, lowered resistance to disease in the industrial districts from the reduction of light, and the congregation of people in the ill-ventilated darkness of the cinemas. No case occurred in a recently vaccinated person. There were no deaths from the disease, although a number of patients were seriously ill and some had very severe eruptions.

The scheme for the conversion of privies made good progress, water-closets being substituted for 1820 of them. The repaving of 1322 yards was completed. The number of houses erected showed a material increase, "but the amount of overcrowding continues to be deplorable." Of 2714 houses erected during the year ended March 31st, 1927, 1752 were municipal. The maternity and child welfare work had outgrown the accommodation in the old premises, and in October the foundation-stone of a new building "with ample accommodation for many years to come" was laid by Sir W. Kingsley Wood. Copies of the elevations, plans, and sections are given in the report. The completed building was opened during the present year by the Minister of Health. A new maternity block with 30 beds has also been opened, and, equipped as it is in a thoroughly up-to-date manner, will be a valuable addition to the maternity and child welfare scheme.

Sheffield has reason to congratulate itself on its tuberculosis scheme. A table in the report shows that of the 16 towns of England and Wales with a population exceeding 200,000, Sheffield had, in 1926, the lowest death-rate from pulmonary and also from all forms of tuberculosis.

The report of the tuberculosis officer, Dr. John Rennie, shows that the dispensary is being well used for consulting purposes. Thus 79 per cent. of the cases notified during the year were sent there before being notified. Again, of the 2203 pulmonary cases dealt with in institutions, 21·3 per cent. were taken in for observation, 54·7 per cent. were at an early stage of the disease, 14·1 per cent. at an intermediate stage, and 9·9 per cent. at an advanced stage. During the year arrangements were made with the guardians to take over all cases of tuberculosis of the lung under their care, and a block of 60 beds for male patients has been allocated for this purpose. There are now 446 municipal beds available for all ages and both sexes of patients, in addition to the 130 beds for surgical tuberculosis at King Edward VII. Hospital. The X ray apparatus at the dispensary is now regarded as indispensable, both for diagnosis and as a record of the chest condition, and 1709 skiagrams were taken during the year. Dr. C. L. Pattison, the surgical tuberculosis officer, reports that the children admitted to his hospital spend a shorter time there, and that in consequence some of the beds are available for areas outside Sheffield. The shortened stay is partly due to improved methods of treatment, but much more to the valuable coöperation of the medical men of the city in sending in the children at an earlier stage of the disease. In 1919 the average duration of stay in hospital was 731 days. In 1926 it was 252 days.

About one-third of Sheffield's milk is produced by 2600 cows stalled in the city. Amongst these, 32 cows with tuberculous udders were found by veterinary inspection during 1926. Rather more than two thirds of the milk comes in by road and rail from presumably about 6000 cows. Amongst these, by the much more unsatisfactory method of following up tuberculous milk samples, the Sheffield veterinary inspectors found 48 cows with tuberculous udders.

Of the 993 samples of mixed milk examined during the year 64 were found to be tuberculous. The number of tuberculous udders discovered by the Sheffield scheme both inside and outside the city during the last five years were 71, 72, 75, 79, and 8

Leeds.

Dr. J. Johnstone Jervis reports that there was a fall both in the deaths and the notifications from tuberculosis as compared with the previous year, but that the figures are still much too high. The reorganisation of the scheme is nearing completion. There is need for more sanatorium beds, however, especially for surgical tuberculosis, and the acquisition of the Elmet Hall estate should make it possible to meet this need. The accommodation in the municipal institutions at Killingbeck and Gateforth is for 220 and 50 respectively; and "The Hollies" sanatorium school for children from infected homes and children with signs of early infection has accommodation for 40 more. Dr. Jervis complains much of the lateness of notification. He would also like to see municipal houses provided at a low rental for families attacked by tuberculosis. It is hoped to add to the scheme the advantages of X ray apparatus, artificial sunlight, and dental treatment. Coöperation with the school medical department has been improved, but closer coöperation between the infirmary and the tuberculosis dispensary is needed, especially in the field of surgical tuberculosis. The notifications during the year numbered 1460, 1299 being pulmonary cases, but only 404 new "contacts" were examined at the dispensary.

"The housing riddle," writes Dr. Jervis, "remains unsolved," and in spite of the erection of 80 houses since the war, and the opening out of new housing estates, there are no signs of an upward movement of the population or of relief of the congestion in the older central parts of the city. During 1926 2065 new houses were erected, of which 17 received State assistance. The municipal houses numbered 780 and are, practically speaking, the only ones built for letting. It is intended to build municipal houses with either gas or electricity as the only form of heating. Eight of these were erected during the year. The West Riding Regional Smoke Abatement Committee sent out a final report to the constituent authorities, and nearly half of the latter have adopted the report in its entirety. Nine of the constituent authorities have decided to provide instructional courses for stokers. The possibility of having an efficiency test for stokers was under consideration, but presents many difficulties. An agreement has been made with the Halifax Corporation whereby the expert services of its smoke inspector will be placed at the disposal of any local authority in the area who desires them. Dr. Jervis regrets that cremation makes such slow progress in Leeds. A table shows that the average number of cremations during the past five years was 18; the corresponding figures for Liverpool and Hull were 76 and respectively. In discussing the matter he refers to the forlorn, dilapidated, and ugly condition of the graveyards in the city. It may be pointed out, however, that many of the graveyards in London have been made beautiful and that the same might be possible in Leeds.

The shortage of hospital accommodation has been mentioned in previous reports. Arrangements have now been made by the guardians for the admission of paying cases to St. James's Hospital, and plans for an up-to-date maternity hospital have been approved.

The 2016 cows stalled in the city are inspected monthly by the veterinary surgeon. Amongst them nine cases of tuberculosis of the udder and six of generalised tuberculosis were found during the ye

Forty-eight samples of outside milk were examined for tubercle, which was found in five of them. The follow-up was only successful in two out of the five cases in tracing the source of infection at the outside farm. The revision course arranged for the midwives at the Leeds Maternity Hospital was repeated this year, but only four midwives attended. Stillbirths during the last decade have averaged 4·3 per cent. of the total births. There are 18 infant welfare centres all managed by the Leeds Babies Welcome Association, and at 15 of them antenatal consultations were held, which were attended by 1658 expectant mothers during the year. The facilities for the provision by the corporation of the services of an obstetric consultant were only used by medical practitioners on 3 occasions at a cost to the corporation of £43.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 12TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 58 (last week 219); scarlet fever, 2016; diphtheria, 316; enteric fever, 146; pneumonia, 892; puerperal fever, 43; cerebro-spinal fever, 8; acute polio-myelitis, 19; acute polio-encephalitis, 2; encephalitis lethargica, 13; dysentery, 8; ophthalmia neonatorum, 92. There was no case of cholera, plague, or typhus fever notified during the week.

Of the 146 cases of enteric fever 58 were notified from the county of Hertford, 48 being from Hemel Hempstead (U. and R.D.), and 9 from Watford (R.D.) (see also p. 1159).

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (2) from enteric fever, 31 (8) from measles, 6 (0) from scarlet fever, 13 (4) from whooping-cough, 24 (8) from diphtheria, 67 (17) from diarrhœa and enteritis under two years, and 47 (8) from influenza. The figures in parentheses are those for London itself. The third death from enteric fever occurred in Bristol. The number of stillbirths registered during the week was 119 in the great towns, including 28 in London.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. A. G. Taylor to be Surg. Comdr.

The following appointments are notified:—Surg. Comdrs.: W. Woodhouse to *Victory*, for Haslar Hospl., and as specialist in anæsthetics; and R. N. W. W. Biddulph to *Pembroke*, for R.N. Barracks, Chatham. Surg. Lieuts.: B. Devane to *Pembroke*, for R.N. Barracks, and to *Calliope* (on completing for trooping), and to *Sandhurst* (on arrival on station); R. L. G. Proctor to *Dryad;* and E. V. Barnes to *Calliope*, for duty on voyage home (on relief).

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs.: J. M. Ryan, L. S. C. Roche (Prov.), R. Oram (Prov.), and C. L. Emmerson. J. D. Cooper to be Temp. Lt.

TERRITORIAL ARMY.

Lt. J. R. Griffiths to be Capt.

INDIAN MEDICAL SERVICE.

The undermentioned relinquish their temp. commns. and retain their rank: Temp. Capts. Bantwal Panduranga Kamalga, Dhirendra Chandra Mazumdar, Joy Devananda Sinha, and Pyare Lal Dube.

The undermentioned relinquish their temp. commns.: Temp. Capts. Krishna Das Mukharji, Chandrian Krishna Sarkar, Atul Krishna Kar, Dara Hormusji Bharucha, Shamsul Haque Wali Mohomed Siddiqui, and Des Raj Nayar.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—This institution is about to be further extended. A new electrical treatment block was opened a year ago, and the present extension will consist of wards superimposed upon it, each containing 26 beds. There will also be three single-bed wards.

Correspondence.

"Audi alteram partem."

CRIMINAL RESPONSIBILITY: MEDICO-LEGAL DIVERGENCE.

To the Editor of THE LANCET.

SIR,—The medical profession must be grateful to Lord Hewart on his delivery of the Lloyd Roberts lecture for his very lucid and logical exposition of the attitude of the criminal law towards insanity. Medicine and law find agreement difficult in this complicated theme. Law is the fruit of ages of human experience, and its maxims are arranged in as logical a manner as may be for the regulation of human conduct. It is, however, in this logical systematisation that psychological medicine finds its stumbling-block. The instance given by the lecturer of the man who is morbidly jealous, develops delusions, kills his wife, and endeavours to conceal his crime is a good one of the divergence of views taken by the lawyer and the physician. The lawyer thinks the killing should not be with impunity. The killer knew what he was doing and no doubt was in possession of knowledge that to kill under such circumstances is to murder. He is therefore in the view of the law to be punished. The physician, on the other hand, is unable to take up so "logical" an attitude or to express so precise a judgment. Anyone with experience of the mentally afflicted has met a case in which the patient suffers from a quality of jealousy which is utterly unreasonable, is not by any known means to be diverted or rectified, takes possession of and entirely vitiates the whole personality and renders him a noisome automaton. Such a patient may "know" what he is doing and "know" that he is doing wrong, but cannot be held to be capable of exercising a normal control over his actions. Similarly, in numerous other analogous but less marked instances the physician learns from his experience of the insane that power of control is in them so often diminished by disease that, though with full knowledge of what they are doing and of the consequences of their acts the patients cannot be held as responsible for their actions as are the sane. It is impossible satisfactorily to bring all insane conduct leading to acts of violence or other wrongdoing within the logical scheme of the answers of the judges given in the inquiry arising upon the McNaghten case. It is, of course, not for the medical witness in a court of law to pronounce any opinion on the responsibility of an accused person, but it is entirely proper that our views in such matters should be insistently laid before the lawyers on all other appropriate occasions.

I am, Sir, yours faithfully,

E. D. MACNAMARA.

Harley-street, W., Nov. 19th, 1927.

THE NUTRITIVE VALUE OF BREAD.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 19th (p. 1093) Drs. Cramer and Mottram write: "It is to be regretted that on the basis of these faulty experiments Prof. V. H. Mottram, in whose laboratory these experiments were carried out, should have published in popular writings the erroneous statement that white bread contains an abundant supply of vitamin B and is not greatly inferior in this respect to wholemeal bread or germ bread, and that as the result of this propaganda this error should have been widely accepted."

May I quote my most recent "popular writing" (*The Nation and Athenæum*, Oct. 15th, 1927), one paragraph of which reads:" The arguments put forward for the use of brown bread instead of white are: that it contains more protein, that its protein is of better quality, and that it yields more mineral matter, more roughage, and more vitamin B. I think that each of these statements is unassailable, and at

the first sight the case for brown bread would appear overwhelming . . . ."

And may I further quote—I hope that the quotation will not be too long for the correspondence columns of THE LANCET—from my other recent "popular" account ("Food and the Family," James Nisbet and Co., second edition, 1926) on the same controversy:—

"*Bread.*—Naturally the first [food] which claims attention is bread, the so-called 'Staff of Life.' Probably it gets that name because every class in society eats so much of it, and because the poor find in it their mainstay. The best that we can say for bread, of any sort or description, is that, as a source of calories, it is cheap. That is why the poor eat it. Further, its flavour, such as it is, is one of which the palate does not easily tire. Bread dilutes the stronger flavours of meat and cheese, and it has an agreeable texture. Whether brown or white it contains vitamin B. These are the sum total of its good qualities. Otherwise it is a poor food *except in conjunction with other foods.* Alone it has too little and too poor protein. Animals grow but slowly upon it, and the stunted growth of the slum child is probably in part due to the poverty of building material in bread. There is no vitamin A nor vitamin C in it, and it leaves an acid ash. Therefore it needs to be fortified by animal protein (meat, fish, milk, or eggs); by fat (preferably containing vitamin A—e.g., butter); by fruit and vegetables for basic mineral substances and vitamin C. White bread contains no roughage.

"Nor is brown bread much to be preferred above white. It has a cleaning effect on the teeth, wherefore dentists recommend it above white; it contains roughage—too much for some people; and it has more vitamin B than white bread. Probably its proteins are a little better, for the male rat asserts his right to a greater stature than the female upon brown bread, upon white he cannot. In these slight superiorities over white there is no basis for the agitation to prevent the use of roller-milled and screened flour which some enthusiasts are raising. Used as a source of calories in a good mixed diet, with meat, milk, vegetables, and fruit, there is no reason to discard white bread. Only, perhaps, when the choice of foods is severely restricted by economy, and bread has to be relied on as the main source of energy, should brown bread be necessarily preferred to white. Otherwise the decision may be left to fancy."

Anyone who had had the patience to read thus far and to compare what Drs. Cramer and J. C. Mottram think I said and what I have actually said must hope that their scientific accuracy is greater than their controversial.—I am, Sir, yours faithfully,

V. H. MOTTRAM.

Nevile's Croft, Potters Bar, Nov. 21st, 1927.

To the Editor of THE LANCET.

SIR,—Dr. Cramer and Dr. J. C. Mottram have subjected some work of mine [1] to criticism, based on, as it seems to me, incorrect reading. No one can object to scientific criticism of scientific work, but it is another matter when the criticism is based on careless reading of or upon misrepresentation of what was actually written and done.

To take one example, they state "This experimental arrangement is obviously faulty, because it does not provide for any controls to show that vitamin B may not have been supplied by the only other article of this diet—namely, butter." Now this control actually was made. In five experiments (12 animals in each experiment) the animals were kept on screens to prevent their obtaining any vitamin B from excreta, and in one of these experiments lasting ten weeks, the only butter-fat they received was "rendered"—i.e., "stirred with hot water until melted and the fat, when cold, allowed to drain through muslin and then pressed as free as possible from liquid." Such washing of the butter is held to remove its vitamin B. The growth-rate of the animals was the same as before. Clearly th samples of bread used must have contained son vitamin B or symptoms of its lack would ha appeared in 70 days. Drs. Cramer and Mottra must have omitted to read this portion of the pape

As far as I know, I have never stated that "whi bread contains a considerable amount of this vitamin and that "the addition of yeast gives to white bre the relative high vitamin B content"—opinions wi which Drs. Cramer and Mottram credit me. Furth they say of my experiments: "the rats kept baking-powder bread and butter showed go growth," while I merely said "the rats fed on bakin powder bread did not thrive as well as the others and in other experiments that "the growth was slow

It is obvious that Drs. Cramer and Mottram ha misquoted me and so given entirely the wro impression of the findings of my work, which go to show that the sample of baker's bread whi I was using in these experiments contained enou vitamin B to supply the needs of the rat.

It is true that there are discrepancies betwe the results of Drs. Cramer and Mottram's and m own experiments, but these discrepancies can easily understood and explained by anyone famili with the current literature on the relation of vitamin to the protein of the diet.

I am, Sir, yours faithfully,

GLADYS HARTWELL.

King's College for Women, Household and Social Science Department, Kensington, W., Nov. 22nd, 1927.

RESIDUAL URINE IN PROSTATIC ENLARGEMENT.

To the Editor of THE LANCET.

SIR,—Many of your readers must have read Cuthbert Wallace's Bradshaw lecture with mu satisfaction and with great appreciation of the criti attitude with which he regards the problems of t surgical treatment of the enlarged prostate. I explanation of the mechanism by which residual uri comes to remain in the bladder after the act micturition, however, I should like to refute.

When the healthy bladder contracts its cavity completely obliterated; as a space it ceases to exi. A single muscle-fibre can only in action contract t certain fraction of its length. If it be stretched t maximal physiological shortening fails to occ. Hence it comes about that the dilated bladder of t prostate loses its power of reducing its inter capacity to nothing. After the greatest effort there still a space which contains residual urine. That t is the explanation can be demonstrated by a sim experiment. If, after the patient has attempted empty his bladder, a soft rubber catheter be pas a certain volume of urine will be drawn off. If n a silver catheter be inserted a further quantity urine will come away. In this second case the tip the catheter impinging upon the apex of the blad will fix it. The power of activity left to the muscu wall will now be sufficient to enable it to contr snugly around the shaft of the instrument, there squeezing out more of the contents. Without su assistance its maximal contraction will still leav bladder space unobliterated. This mechani explains why the bladder will be emptied by a me catheter, even when the eye is at the highest point its cavity, as is usually the case with the pati lying upon his back.

The amount of residual urine is thus a measurem of the degree of stretching that the bladder h undergone and becomes of supreme importance. I when it amounts to about 4 oz. the areas of the urete sphincters are so expanded that the sphincters beco incompetent. Then it is that at every act of mict tion the intravesical pressure, far greater than secretory pressure of the kidney, can be and transmitted upwards along the ureters to the kidn themselves. In this sense the term "back pressur is applicable and expressive. This hypothesis wo

em to be more plausible than that of Sir Cuthbert allace, who assumes that the damage to the kidney due to renal secretory pressure, which would only tenable if the pressure of urine in the bladder were ntinuously raised (which it is not) or the sphincter the ureter went into continuous spasm for which ere is no evidence.

Surgeons will thank Sir Cuthbert Wallace for his marks upon the propriety of distension for the rest of hæmorrhage and his suggestion that the erits of the open operation should be reconsidered.

I am, Sir, yours faithfully,

urrey, Nov. 22nd. CHARLES A. PANNETT.

TREATMENT OF ENCEPHALITIS LETHARGICA: A SUGGESTION.

To the Editor of THE LANCET.

SIR,—The very multiplicity of remedial measures vocated for the treatment of "sleepy sickness" dicates that the therapy of this disastrous disease in a very unsatisfactory state. This is undoubtedly e case even though, to judge from the literature, neficial results are occasionally obtained by the use sodium salicylate, mercurochrome, hexymethylena- ne combined with sodium acid phosphate and a v other remedies, amongst them a serum. One sitates to add to the number of drugs which have en tried in, or suggested for, the treatment of the ate stage of the disease, but, when the results are so satisfactory and the sequelæ of the malady so grave, th from the individual standpoint and that of the blic health, it is perhaps justifiable to advance an gument in favour of a trial of potassium perman- nate intravenously. I am encouraged to do so by e fact that there would certainly seem to be some sis for the use of this substance.

Many years ago Dreyer in Cairo showed that the ernal application of solutions of permanganate of tash is of marked benefit in small-pox. I drew ention to the matter in 1922 (THE LANCET, 1922, 1193) and, at a meeting of the Army Pathology mmittee, discussed the question of the action of rmanganate in this disease with Dr. Mervyn Gordon. a later date Dr. Gordon published an account of his eresting work on vaccinia and variola and showed t potassium permanganate, in a dilution of 1 in 0,000, is capable of destroying the virus of that ease and that it can also destroy the virus of variola a dilution of 1 in 10,000.

There is good reason for believing that the virus of ephalitis lethargica has a certain affinity, probably close one, with the viruses of vaccinia and iola as well as with the herpetic virus. This being s it occurred to me some time ago that potassium manganate might possibly be capable of acting on the virus of encephalitis lethargica. It seemed ar, however, that it could only do so if it were ministered intravenously and, from the nature of drug, I very much doubted if it could be given this route.

With a view to determining its action when given the vein I asked Dr. H. H. Scott if he would carry some experimental work on rabbits. He very dly did so, but had to abandon his investigations being appointed pathologist to the Zoological iety of London. The few data which he collected did seem to me to warrant a trial of the drug in cases encephalitis lethargica, and the matter fell into ayance for the time being. Now, however, I see m the *Indian Medical Gazette* for September, 1927, t J. H. Theodore, I.M.S., military assistant surgeon the King Institute, Guindy, impressed by the value permanganate of potash externally in small-pox l by the work of Gordon on vaccinia, has been ting the efficacy of the drug in vivo as a means of troying the viruses of vaccinia and variola. After eriments on the intravenous injection of per- nganate of potash in rabbits and after finding that, en in this way, the drug appears to exercise a cific and favourable effect on vaccinia in these mals, he proceeded to administer it intravenously in small-pox cases. So far he has only treated three cases in this way, proceeding with great and commendable caution. Naturally no conclusions can yet be drawn as to its efficacy in small-pox, but he has shown that the drug can be safely administered to human beings by the intravenous route, at least in doses of 10 c.cm. in a 1 in 500 solution. A single dose only was given in each case, but he considers that the maximum dose which could be tolerated is probably much in excess of that employed, a conclusion which seems justifiable, as he gave the same doses to his small-pox patients as to his vaccinated rabbits. In the doses he employed potassium permanganate administered intravenously exhibited no toxic properties.

It is of interest to know that Dr. Theodore tested the effect of 10 c.cm. of a 1 in 500 solution of permanganate of potash on himself before administering it to his small-pox patients. He found that it did not affect either liver or renal efficiency. As, therefore, this form of medication can, judging from Theodore's results, safely be employed in man, I think, for the reasons stated, that it might be tried in encephalitis lethargica, especially perhaps in cases where other remedies have proved futile or of little use. I am endeavouring to have such trials carried out and, at a later date, trust it may be possible to report upon them.—I am, Sir, yours faithfully,

London School of Hygiene and Tropical Medicine, Nov. 21st. ANDREW BALFOUR.

ORGANIC HYPNOTICS.

To the Editor of THE LANCET.

SIR,—In an Editorial note following our letter on page 1101 of last week's issue of THE LANCET it is stated, "These drugs have been placed on a statutory list of dangerous drugs." We should like to point out that the statutory position of Dial and barbituric acid derivatives generally is that they are legally regarded as Part I. Scheduled Poisons. The suggestion that they have been placed on a statutory list of dangerous drugs will cause your readers and the profession generally to assume that Dial is legally classed as a Dangerous Drug.

We are, Sir, yours faithfully,

Nov. 18th. THE CLAYTON ANILINE COMPANY, LTD.

*** We have received a similar representation from the Hoffmann-La Roche Chemical Works, Limited, but we are unable to agree that the use of the words "dangerous drugs" (not Dangerous Drugs) in our Editorial note would mislead professional readers. They would presumably know that neither the Dangerous Drugs Acts of 1920 and 1923 nor the Regulations issued thereunder contain any definition or statutory list of dangerous drugs so-called. We are surely entitled to speak of a poison as a dangerous drug when the Dangerous Drugs Acts themselves deal with the sale of poisons under the Pharmacy Act as well as with the restrictions on the possession, &c., of raw, prepared and medicinal opium.—ED. L.

EXTENSION OF THE MILLER GENERAL HOSPITAL.

To the Editor of THE LANCET.

SIR,—In reference to your note on p. 1083 of last week's issue may I say that our extensions, *which we are just taking into use*, consist of: 1. A new ward block containing three fine wards of 24 beds each, with two private rooms for paying patients on each floor. In the basement there is a dining-room and a class-room for the nurses, a servants' dining-room, a new main kitchen, larders, cold storage and ice-making plant, store-rooms, &c. The roof has been designed for giving open-air treatment with a shelter for use in inclement weather. 2. The first part of a nurses' home which will contain 73 bedrooms. The two buildings are costing £100,000, towards which King Edward's Hospital Fund have promised us £16,000 when the remainder (which now stands at £22,000) has been raised.—I am, Sirs, yours faithfully,

HARRY A. BONE,

Greenwich-road, London, S.E., Nov. 18th. Secretary

Obituary.

GEORGE COWELL, F.R.C.S. ENG.,

CONSULTING SURGEON TO THE WESTMINSTER AND THE ROYAL WESTMINSTER OPHTHALMIC HOSPITALS.

WE regret to announce the death of Mr. George Cowell, which occurred at his residence in Nevern-square, London, on Nov. 18th, at the great age of 92. He had outlived all his contemporaries, but to the end maintained a large circle of friends within and without the medical profession, generations of the former having been his pupils or having served with him as his juniors in various capacities.

George Cowell was the son of an Ipswich surgeon of the same name and was born in the last year of the reign of King William IV. After serving articles to a practitioner in Birmingham, as was the method of joining the medical profession in those days, he entered St. George's Hospital as a student, and held minor and residential appointments under Gray, the anatomist, Prescott Hewett, and Timothy Holmes. In 1858 he took the diploma of M.R.C.S. and shortly afterwards was appointed surgeon to the Saints George and James Dispensary. At the same time he became clinical assistant at the Moorfields Hospital, where he studied his special branch of surgery for ten years, though he remained for a long period a general surgeon like other ophthalmologists of his date. In 1867 he took the Fellowship of the Royal College of Surgeons of England and was shortly afterwards appointed assistant surgeon to the Westminster Hospital, with which institution he was connected until the day of his death, that is for no less than 56 years. Throughout the whole time he served the charity nobly. He lectured at the hospital on surgery for 20 years, and being promoted full surgeon in 1878 held that post until he was appointed consulting surgeon in 1896. The period covered the rebuilding of the out-patient department, the medical school, and the chapel, with all of which work he was closely associated. He was Dean of the school for five years, and at the expiration of this office he became treasurer of the hospital and held that post for a further 15 years. While still assistant surgeon to the Westminster Hospital he was appointed surgeon to the Royal Westminster Ophthalmic Hospital, a post which he held for 27 years; and here again not only did he give his scientific services but he took an active interest in the management of the institution.

Next to his work as an ophthalmic surgeon, and closely associated with that work, must be mentioned Cowell's activities in behalf of children. In 1866 he was the virtual founder of the Victoria Hospital for Children in Chelsea, and for 20 years he was associated as surgeon and ophthalmic surgeon with the new institution. During the same period he found time to hold the appointment of surgeon to the East London Hospital for Children, and also to lecture on surgery and ophthalmology at the School of Medicine for Women founded at the Royal Free Hospital in 1874.

As an author Cowell is well represented by his clinical addresses, and by the many papers contributed to the reports of St. George's Hospital, Westminster Hospital, and the Westminster Ophthalmic Hospital, while special reference must be made to his lectures which were published in THE LANCET at various periods from 1880 to 1887. The greater part of his writing consisted of notes on surgical procedure and records of special operations; these were published in various medical journals as well as in our columns and show the wide range of their author. He also was the author of "The Life and Letters" of his relative, Edward Byles Cowell, the well-known Oriental scholar.

It was natural that Dr. Barnardo should turn to Cowell for assistance when the well-known Homes for neglected children were founded, and no medical man did more than he for the establishment of this fine philanthropy upon sound grounds. No doubt its religious side had particular attraction for him as he was a zealous supporter of the Guild of St. Lul and except for the Rev. Canon Henry Arnott w at his death the senior brother of the Guild; on t chronological roll of the Fellows of the Royal Colle of Surgeons of England Cowell's name stands seco and Arnott's fourth.

Mr. W. G. Spencer writes of his old friend: "I h the honour of being Cowell's colleague at the We minster Hospital, but when I was elected he h already been senior surgeon and the senior on t medical staff for many years. It was well kno that he had headed the efforts of the staff in all t various improvements at the hospital and in t medical school, of the history of which he possess profound knowledge. Soon after my appointme he called a meeting at his house, at which the la Charles Stonham and I were invited to express o opinions. Mine, naturally, were those which I h picked up during six years of work at St. Bartho mew's, and I remember Cowell's courteous attenti intent on making the machine work smoothly, as did, until his retirement nine years later. In gene surgery he was level with his day; he accept Lister's methods without attempting to extend t scope of surgery which those methods facilitat Indeed, the special attention he had devoted ophthalmic surgery disposed him to smaller operati and finer manipulations. I had watched Her Power and Bowater Vernon when operating cataract, as I did subsequently Cowell, and I thi that his handwork was not then to be better After retirement from the active staff he attend hospital committees as a vice-president, at first re larly and then with decreasing frequency, and t last occasion occurred when he led the medical st at the service in the Abbey commemorating t reopening of the hospital after alterations in July, 192

George Cowell was, as this brief notice shows, learned and conscientious man, whose high standa of living and devotion to duty enabled him to act a pioneer in good works and to offer firm supp to colleagues in the discharge of joint responsibiliti

He married late in life Elizabeth, widow Dr. Hamilton Roe, and daughter of Mr. John Laur M.P.; there were no children and his wife p deceased him.

JONATHAN DALGLIESH, M.R.C.S. ENG.

Dr. Dalgliesh, who died at Newcastle-on-Tyne Nov. 9th, was born in 1839, and was educated the Newcastle College of Medicine. He spent m of his life in his native city, for after a short peri in London, where he qualified as L.S.A. a M.R.C.S. in 1862, he returned to the North practise as assistant to Dr. Raine and later to J Frederick Page. At the time of his marriage he s up in practice by himself and he remained co tinuously at work in various parts of the city un 1901. In that year he retired and went to live Harrogate, but on the death of his wife soon afterwa he returned to Newcastle, and for 11 years carri on, single-handed, a medical mission at Shieldfie A serious illness followed, but soon after the w broke out Dr. Dalgliesh was well enough to return practice once more to take the place of a young man, and gave much useful help, especially as anæsthetist to Newcastle practitioners and hospita Even after his final retirement in 1919 he took great interest in medical work and progress, and acted as public vaccinator until 1921. We ha received the following appreciation which spea further to his personal qualities: "He was a m energetic man and a real doctor; the best type general practitioner, always anxious to relie suffering and cure disease, and as anxious to lea and improve his knowledge of the science and art medicine and keep abreast of the times. He w most self-denying and never weary; I never on heard him say that he was tired, and he wou cheerfully work day and night in times of epidemi His generosity was as great as his courage, and it w always his earnest desire to promote peace and hap

s among those around him. Surely he can say h St. Paul, 'I have fought a good fight.'" During last few years of his life he suffered from failing s of sight and hearing, and these disabilities, ugh he bore them with patience, were a considerable uble to him, for he had drawn much pleasure n books.

)f Dr. Dalgliesh's five sons, the second, Dr. C. A. gliesh, was an ophthalmic surgeon in Sunderland died in 1910. His eldest son is Dr. J. W. gliesh, of Sutton. He leaves three daughters.

WILFRID WILLIAM PEARSE, M.D. ABERD., D.P.H.

)r. W. W. Pearse, late medical officer of health of ng-Kong, was a Devonshire man, his father being hysician before him. He received his medical cation at the University of Aberdeen, where he luated as M.B. in 1893 and took the D.P.H. in 4. After qualification he travelled extensively in East and eventually joined the Colonial Medical vice. He held the appointment of assistant lical officer of health at Hong-Kong for several rs before his promotion to the senior post, and ng this time he devoted considerable attention to plague work; his thesis for the M.D. in 1906 on the subject of bubonic plague, and was classed he best of the year. During the late war Dr. rse joined the Royal Army Medical Corps, rning to England via Siberia for the purpose, an ıtful journey in those times of difficult travel. saw service in France, and at the conclusion of ilities resumed his work in Hong-Kong. On hing the age-limit, he retired in 1926, after nearly years' service in the Colony. The Chinese staff e him a picturesque farewell dinner and he ived many gifts from friends and colleagues. was a man of unusual ability, whose learning was) and curious. He read widely, was an accom- ed linguist, and took a keen interest in microscopy bacteriology. His knowledge of public health, cially in the Far East, was excelled by few, and vas only his extreme modesty and dislike of icity which prevented his becoming well known his field of work. His talents were eminently ted for research, but he was not given facilities he Hong-Kong Government, and thus the greater of his time was devoted to the varied activities ne sanitary department, to the loss of epidemio- al science. He put all his energy into bringing department to a high state of efficiency, and it esented his life work, for his long service in the ics undermined what had been a strong consti- n, and he left Hong-Kong with little hope of ining his health.

. Pearse, whose death took place at Villefranche- ner on Nov. 11th, had many friends who will deeply t his untimely death. He leaves a widow and g daughter.

JOHN CARLYLE JOHNSTONE, M.D. GLASG.

. Carlyle Johnstone, whose death is announced, for many years medical superintendent of the burgh District Asylum at Melrose, and though d lived in retirement at Droitwich for some years, well remembered in the North by a large circle d colleagues. He was visiting a medical friend dinburgh at the time of his death, which came pectedly and suddenly. Born at Hobkirk, in county of Roxburgh, in 1855, he was educated rivate schools in England, Dumfries Academy, the University of Glasgow, where he graduated edicine in 1877 with distinction in most of his cal classes, having gained five medals. In the wing year he was appointed assistant medical r at the Fife and Kinross Asylum, and in 1880 ecame assistant physician to the Royal Edin- h Asylum, under the late Sir Thomas Clouston, n he assisted in the preparation of his "Clinical ures." In 1885 he went to the Roxburgh District um as medical superintendent, and there he remained until 1917, when he resigned on account of ill-health. During the period of his control the institution expanded considerably; fresh land was purchased, a new and satisfactory water-supply was obtained, and electricity was installed.

Dr. Johnstone was greatly interested in the nursing of the insane and devoted much energy to training his nursing staff. He was partly instrumental in securing the passage of the Act under which service in the Scottish District Asylums became pensionable, and he drew up a scheme of practical training for those engaged in mental nursing, which was found useful in other institutions. He also took an active part in the work of the local division of the British Medical Association, and was elected by the county council as a medical member of the Roxburgh County Insurance Committee. A few months after his resignation Dr. Johnstone was sufficiently restored to health to take up work under Dr. G. M. Robertson, as junior assistant physician at Craig House Mental Hospital, and he remained there until some months after the Armistice. His private interests were chiefly literary and artistic. A man of wide reading he was unassuming in character and averse to the limelight. "He was always ready," writes a colleague, "to place his experience and knowledge at the disposal of anyone who sought his advice and guidance, and his best memorial is the institution which he served so long and so well, and which under his able management became a model of what such an institution should be."

Dr. Johnstone is survived by his wife, a daughter of Deputy Surgeon-General Andrew Fleming, of the Bengal Army, and by a son and daughter. His son is at present medical officer of health at Nairobi in Kenya.

HOUSEKEEPING IN INSTITUTIONS.

THE task of catering for an institution of any kind, be it hospital, school, nursing home, hostel, or Poor-law institution, if it is to be well done from the health point of view and yet cheaply, calls for special preparation and high qualifications on the part of the woman who undertakes it. In a pamphlet entitled "The Reform of Institutional Housekeeping: A New Career for Women," which has been issued by the Food Education Society (24, Tufton-street, London, S.W. 1), Mr. C. E. Hecht outlines the dietaries which now obtain in hospitals and nursing homes, boarding schools, and hostels, and goes on to describe the steps which the Society has taken since 1910 to improve the situation. America and Canada, he points out, have gone much further than this country in training women to hold posts as dietitians in institutions. Several leading hospitals only accept candidates who hold a degree in household science, and this involves an academic training of four years, followed by a professional training, usually of six months, in the dietary department of a hospital. The result of employing these dietitians has given great satisfaction to the boards, the medical staff, and to the patients. Mr. Hecht considers that in England the problem of feeding in the hospitals has not yet received much attention and that the people into whose care it is entrusted are not experts. He recognises improvements of late years; since 1925 the Metropolitan Asylums Board have only appointed fully trained and experienced women to act as kitchen superintendents in their hospitals; facilities for training women are also afforded in many schools, notably by King's College for Women, which offers a three years' course in institutional administration; the University of London, too, grants a degree in household and social science. Yet qualified women are far too seldom employed, and he suggests that governors and committees of hospitals, schools, and other institutions must be made to realise that the presence of an educated and highly trained woman makes for efficiency and economy as well as the health of the residents. As a considerable time must elapse before reform on a large scale comes into force, it is suggested that post-graduate courses in dietetics should be arranged for hospital matrons, heads of schools, homes, residential halls, and other institutions, as well as for housekeepers and cooks.

ROYAL HALIFAX INFIRMARY.—A gift of £10,000 has been received from Mr. Ernest Shaw Redman for the provision of two open-air wards and the building and equipment of a pathological laboratory.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.

NEW OUT-PATIENT AND ELECTRICAL DEPARTMENT.

ON Tuesday last Prince Henry, President of the Royal National Orthopædic Hospital, received the guests at the formal opening of the new out-patient department by the Lord Mayor of London. A preliminary religious service was conducted by the Dean of Westminster. In welcoming the Lord Mayor, Prince Henry assured the company that the new building was already entirely paid for, and had been erected with a stern eye to economy. It had not come too soon, for in 1908, when the main buildings had been opened, the annual number of out-patients had been 11,000, and the aim had been to provide for 20,000. Last year the number had approached 78,000. The decorations marked a new era, in which patients were to be cheered by beauty instead of depressed by the gloom of a railway station waiting-room.

The Lord Mayor, in reply, complimented the hospital on its success and on the work it did for middle-aged patients as well as children. After he had declared the new buildings open, the President and guests made a tour of the various rooms, and saw patients at exercise in the gymnasium, clad in their purple tunics.

The New Waiting-room.

The extension, which is approached through a new main entrance in Bolsover-street and a wide bright corridor, centres round a large and attractive waiting-room. Broad mahogany doors lead to the various departments through five bays on each side of the hall and two at the far end. Below the mid-line of the bays the colour is dark ivory; above it is light ivory. Above the doors in each bay are paintings representing the months of the year, the work of Miss Nan West, a young artist trained at the Slade School. A big panel representing a picnic scene, "June and July," is at the far end of the room, between the two doors. The medium is a washable wax, and the execution is consistently gentle, with a quiet gaiety; a fitting expression of the desire hopeful and happy patients. Above the frieze roof is coved, and the cove is broken by large se circular windows above each of the ten side ba which are separated by pillars. The lighting is opal electric globes, suspended opposite each win space.

The Treatment Rooms.

Off the waiting hall are the consulting and dress rooms, an operating theatre for minor operati and sterilising, anæsthetising, plaster, and recov rooms. Leading from the hall is a corridor wh gives access to rooms in which patients are measu for and fitted with surgical boots, instruments, The exit is from the further end of the hall and le into Euston-road, so that cross traffic within hospital is eliminated. A second corridor from hall leads to the electrical department. The old o patient department has been remodelled and adap

Waiting-room of the new out-patient department of the Royal National Orthopædic Hospital.

for physio-therapeutic treatment, and contains ro for all the modern forms of electric massage light treatment, the old hall itself being used a gymnasium. The old electrical department has been reconstructed, and now contains a large ro for X ray work with dark room adjoining, as wel accommodation for medical officers, waiting patie and private treatment. The basement under the out-patient department is filled with large worksh for instrument makers. These are well lit and ve lated and contain the most modern machinery instrument work. The front portion of the build facing Bolsover-street has a first and second flo the first floor provides quarters for medical offic and a large lecture and reading room, whilst second floor consists of bedrooms for nurses. further feature is the provision of panel heat which warms wall and ceiling surfaces, and elimin pipes and radiators, thereby leaving fewer places dust and dirt to collect.

This hospital has also an in-patient departmen Great Portland-street of 200 beds, and a cou branch, in itself a fully equipped hospital, 11 miles away, with over 200 beds. The sum £40,000 is wanted to complete the extensions at country branch at Stanmore, which will provide cases of crippling from infantile paralysis, from b

formities and rickets, and from surgical tuberosis. This was the first hospital in the country to nbine education with treatment, and the children leaving the hospital can compete on equal terms h their more fortunate brothers and sisters.

IE OUTBREAK OF PARATYPHOID IN WEST HERTFORDSHIRE.

THE recent outbreak of paratyphoid B involved ts of the borough and rural district of Hemel mpstead and the adjoining border of the rural trict of Watford. The date of onset of the first e was Oct. 25th, and the majority of cases veloped during the first week of the present month, brunt of the attack falling on the 4th. Up to e 134 cases have been notified; the epidemic is v on the wane as only a few delayed cases have n reported during the past week. The type of er was early detected by means of the Widal ction and the clinical features in the early and sequent cases were characteristic of paratyphoid B. mmediately the existence of the outbreak became wn steps were taken to provide adequate hospital ommodation and to deal with the source of infec-n. As the notifications came in it became apparent t, although many of the cases were separated by a siderable distance, there was one factor common all—namely, the milk-supply. Steps were taken ecure the sterilisation of the supply from a certain y. This dairy received milk from ten different rces, one of which was pasteurised. The next step to examine the blood of all those who were in any concerned with handling the milk at the dairy to ascertain the conditions obtaining in the nine ns which sent supplies to the dairy, more especially n reference to the presence of any recent case of ss. The results may be summarised as follows:—

Two cases of paratyphoid occurred at the dairy, one he 11th and the second on the 17th. These were ediately removed to hospital.

Blood tests showed that the dairyman and five of his dsmen gave a positive or partially positive Widal tion. They were all removed to hospital for examination whether they were passing *paratyphosus B* in fæces or e.

At one farm a case of illness was discovered, the nt being a child, aged 3½, who subsequently gave a ive Widal reaction. This farm also supplied directly houses with milk and in one of these houses two cases aratyphoid occurred. This child, with her mother, was ved to hospital.

seems that the primary source of infection was child at the farm who infected the milk supplied he retailer, and through this induced a secondary ce of infection by infecting some of the members he dairyman's household and his staff. A second n was under suspicion where there was an oldier who had been in Mesopotamia, but samples blood gave negative results. All the milk lied from the nine farms has been examined eriologically.

he removal to hospital of over 100 cases was not ated by the gravity of their condition, but was rded as an essential precautionary measure. No s will be discharged until they are proved to be carriers of *paratyphosus B*. The general type of disease was mild although some serious cases rred; so far there have been no deaths. The t was acute with high temperature and headache, rged spleen, and constipation (occasionally diar-a). The paratyphoid exanthem was well marked, s appearing in some cases on the arms, and ed useful in diagnosis.

OYAL SUSSEX COUNTY HOSPITAL.—The casualty emergency departments of this hospital have long been ed to the utmost to meet the daily call made upon , arising in the main from the modern conditions of port and motor traffic. A donation of £10,000 has been given by Mr. Bernhard Baron towards the contion of a new department.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 16TH.

Treatment of Young Offenders.

Mr. CADOGAN asked the Secretary for the Home Department what steps he proposed to take to give effect to the recommendations of the Young Offenders Committee.—Sir W. JOYNSON-HICKS replied: The report of this Committee covers too wide a field to be dealt with fully in an answer to a question, but I will make a short statement. Generally speaking I accept the principles of the Committee's scheme for dealing with neglected children and young persons and with young offenders under 21, though I must not be taken as endorsing all its recommendations, some of which involve difficulties on financial or other grounds. Many of the recommendations do not require legislation. For instance, a great deal can be done by justices under their existing powers to establish juvenile courts on the lines recommended by the Committee. On Sept. 30th I sent out a circular on the subject to every court of summary jurisdiction, and I hope that all justices will take the opportunity of reviewing their procedure in the light of the suggestions made. In London I have appointed a small committee to consider the organisation of the juvenile courts. Some other proposals to which effect can be given by administrative action are being dealt with as quickly as possible. As regards recommendations which involve legislation, I have already given instructions for the drafting of a new Children Bill to amend and possibly to consolidate the Children Act of 1908. This is a task which will take time to complete, but there will be no avoidable delay. It would be premature at the moment to say when it will be possible to introduce a Bill. It is hoped to include not only many of the recommendations of the Young Offenders Committee, but also some of the suggestions of the Sexual Offences Committee concerning child welfare and of the Child Adoption Committee relating to the registration of voluntary homes. Some of the proposals of the Young Offenders Committee would involve considerable expenditure from public funds, and, as the House will readily appreciate, the consideration of these is affected by the financial situation. As I said in answer to a question the other day, I am in favour of Central Remand Homes, but there are difficulties—administrative as well as financial. The Committee did not enter fully into the details of its proposed scheme, but I am taking steps to examine the problem and to ascertain whether anything can be done now, even if only by way of an instalment of a fuller scheme. As regards Borstal institutions, there is already a need for one new institution, and I hope that this may be provided as soon as the financial situation permits. I sympathise with the desire of the Committee to avoid the imprisonment of young offenders under the age of 21, and I propose to explore every avenue which may help to the attainment of this object so far as it is justified and practicable, but there are some cases in which a sentence of imprisonment is called for. Every encouragement is being given to the development of the probation system, and I am considering the best way of extending the resources of that system by the use of hostels on the lines suggested by the Committee and in other directions. The report of the Committee is receiving, as it deserves, the fullest attention.

Importation of Foreign Skimmed Milk.

Sir ARTHUR HOLBROOK asked the Minister of Health whether it was proposed to prohibit the importation of skimmed milk, which was exempted from the standards of quality and purity with which British farmers had to conform, and whether the result of inquiries had established that the skimmed condensed milk so imported was not fit for human consumption.—Sir KINGSLEY WOOD, Parliamentary Secretary to the Ministry of Health, replied: The inquiries which my right hon. friend caused to be made in Holland and Denmark show that the condensed skimmed milk which is imported from those countries is produced under conditions as good as those existing in this country. My right hon. friend is advised that the commodity is certainly not unfit for general consumption, and he cannot take any steps to prohibit its importation on grounds of public health.

Pithead Baths.

Mr. GRUNDY asked the Secretary for Mines the total number of pits with pithead baths and the number of baths provided.—Colonel LANE-FOX replied: Excluding slipper baths, plunge baths, swimming baths, and baths provided for officials only, 32 pithead bath installations had been completed by the end of 1926 and four were in course of construction. The number of bath cubicles in these installations is 1954. I know of at least one additional installation

with 66 cubicles which has been commenced during the present year by the Miners' Welfare Committee, but I shall not have complete returns for 1927 until early next year.

Accidents at Mines.

Mr. GRUNDY asked the Secretary for Mines to give the latest available figures of fatal and non-fatal accidents to persons employed at the mines and the corresponding figures for 1925 and the percentage in both periods to the number employed.

Mr. WILFRID PALING asked the Secretary for Mines to give the number of accidents, fatal and otherwise, in mines from January, 1927, to the last convenient date.—Col. LANE-FOX replied: During the first ten months of 1927 there were 943 deaths from accidents at mines under the Coal Mines Act and 3889 persons were seriously injured. The death-rate per 1000 persons employed was ·91 and the serious injury rate 3·76. The corresponding figures for the first ten months of 1925 were 923, 3607, and ·82 and 3·22 respectively. I regret that comparable figures as regards the less serious non-fatal accidents are not yet available.

Cost of Food in Poor-law Establishments.

Mr. CECIL WILSON asked the Minister of Health the average weekly cost per head for food and drink in the case of children's homes, men and women, respectively, in Poor-law institutions, apart from the hospitals and in asylums.—Mr. CHAMBERLAIN replied: According to returns furnished to me the average weekly cost per inmate for the year ended March 31st, 1926, of the provisions supplied to the inmates of the separate Poor-law establishments for children (other than institutions wholly appropriated to sick children) in England and Wales for which separate accounts are kept, was 4*s.* 7*d.* According to the same returns the average weekly cost per inmate, for the same year, of the provisions supplied to the inmates (men, women, and children) of the general Poor-law institutions (i.e., institutions other than those wholly appropriated to the sick and mentally infirm and establishments for children in cases where separate accounts are kept) was 5*s.* 5¼*d.*

Vitamin A and Food Values.

Viscount SANDON asked the Minister of Health whether his expert advisers had examined, and would issue a report on the relative figure value as to vitamin A of sheep and oxen liver fats and the best butter for children.—Mr. CHAMBERLAIN replied: The occurrence of vitamin A in a variety of foods, including ox and pig liver and butter is dealt with in the "Report on the Present State of Knowledge of Accessory Food Factors (Vitamins)," issued by the Medical Research Council. The report does not contain any specific reference to sheep's liver, but I am advised that there is no reason to suppose that this article would differ materially from ox liver.

THURSDAY, NOV. 17TH.

Lease of Bellahouston Hospital.

Mr. BUCHANAN asked the Minister of Pensions if he had yet come to any agreement with the Glasgow Corporation as regards the continuance of the lease of Bellahouston Hospital; if so, for how long; and if he had considered any alternative building for the future.—Major TRYON replied: I am informed that the Glasgow Corporation have resolved that the Ministry's present lease of the site of Bellahouston Hospital be extended to Whitsuntide, 1929. The question of the provision to be made for patients after that date will receive the attention of my department.

Government Lymph Stocks.

Mr. GROVES asked the Minister of Health if he would state what were the original sources of the vaccine lymph stocks at present in use at the Government lymph establishment; what substances were now added to the lymph in the process of manufacture; and whether the lymph material was completely sterilised before being issued so as to secure that it should contain no living disease germ.—Mr. CHAMBERLAIN replied: The records show that the lymph now used at the Government lymph establishment is derived from calf lymph originally obtained from Cologne, and the strain has since been carried on by repeated transference from animal to animal. The substances now added to the lymph are glycerine, distilled water, and oil of cloves. The lymph complies with the standards laid down in the Regulations made under the Therapeutic Substances Act, 1925, but it is not completely sterilised, as otherwise its active principle would be destroyed.

Insured Persons and Dental Treatment.

Mr. WILLIAM M. ADAMSON asked the Minister of Health whether he could give under national health insurance the total number of dental treatment cases and the cost for the six months of the financial year.—Mr. CHAMBERLAIN replied: The complete information asked for by the hon. Member is not available. Certain figures have, however, been obtained from a number of the largest societies, with a total membership of over 6,000,000 insured persons, and these show that during the 12 months from July, 1926, to June, 1927, the number of claims for dental benefit sanctioned by these societies was 571,435, at a cost to the societies of £1,426,82 It is estimated that the total number of claims sanctioned in the year by all approved societies was about 1,100,0 and the cost about £2,500,000.

Old Age Pensioner and Disqualification.

Mr. ROBINSON asked the Minister of Health if his attention had been drawn to the case of Mrs. S. A. Helliwell, Prescott-terrace, Stainland, Halifax, who had been deprived of her old age pension on the ground that she is an inmate of St. Luke's Hospital, Halifax, a Poor-law institution, despite the fact that she entered the institution on the advice of her private doctor, was a paying patient, and had paid poor and district rates for her private dwelling; and whether he would issue instructions for the old age pension to be reissued with arrears from the date of suspension.—Mr. CHAMBERLAIN replied: An appeal by Mrs. Helliwell against the decision of the local pensions committee, that she has become disqualified for continuing to receive an old age pension by reason of having been an inmate of a Poor-law institution for the purpose of receiving medical or surgical treatment for a period exceeding three months, was received by me on the 12th instant. The case is now under investigation, and a decision will be given as soon as possible.

Horses and Chemical Warfare Experiments.

Mr. CADOGAN asked the Secretary of State for War the number of horses which died in the course of, or had to be destroyed as a consequence of, experiments at Porton chemical warfare station during August, September, and October, respectively; and whether the use of animals in these researches could now be dispensed with.—Sir WORTHINGTON-EVANS replied: No horses were used in experiments at the Porton chemical warfare experimental station during the months referred to. As regards the latter part of the question, experiments with animals are unfortunately essential in order to obtain the necessary data for ensuring adequate defence against poison gas and for evolving efficient methods of treating gas casualties.

Bodies of Paupers and Anatomical Research.

Mr. DAY asked the Minister of Health whether he had received any protest from boards of guardians in reply to the letter issued by his department asking the boards of guardians to hand over the bodies of paupers who die in their institutions, and who were without friends and relations to the medical schools for anatomical purposes; and whether poor and friendless persons were given an opportunity of specifying before they died what should be done with their bodies after death.—Mr. CHAMBERLAIN replied: Some boards of guardians have declined to exercise their powers under the Anatomy Acts, but I am not aware that any protest has been received. As regards the second part of the question, any inmate of an institution may express a desire that his body shall be interred without anatomical examination, and Section 7 of the Anatomy Act, 1832, provides that such a wish shall be respected.

FRIDAY, NOV. 18TH.

Landlord and Tenant Bill.

On the motion for the third reading of the Landlord and Tenant (No. 2) Bill,

Mr. DALTON complained that the measure was small and inadequate. Professional men were wholly excluded from the benefits of compensation for goodwill and they were only brought in as an afterthought and largely as a result of pressure from Members of the Labour Party in Committee. They were brought in to some extent in respect of compensation for improvements, but they were given far less than one-half of that to which they were entitled. The professional man, the doctor, the dentist, and so on, stood to gain very much more from a recognition of his right to compensation for goodwill than from a recognition of his right to compensation for structural improvements, which comparatively speaking such tenants seldom made, and therefore the professional man got next to nothing out of this Bill. But even so small, so miserable, and so paltry a measure would command the support of the Labour Party because they regarded it as the very thin end of a second wedge. That wedge having been inserted into the door they hoped to drive it in a great deal further in future.

Sir P. PILDITCH said the principal change undoubtedly which the Bill brought about was that in respect of all business premises and also a large number of premises of a residential character occupied by professional men, the whole of the settlement of questions arising between landlord and tenant would be taken out of the region of private arrangement and out of the play of supply and demand and free contract and placed in the hands of the tribunal.

ieved that if the tribunal were used, and if the provisions the Bill itself were very largely used by landlord and ant, it would not produce the desired effects. In that nt there would be uncertainty in regard to property ich had been apprehended by most of those who had picions about the Bill, and the general result would be t instead of it doing any good to either landlord or tenant re would be a general rise of rents. He hoped that the would not operate in detail at all, but that it would uce landlords and tenants to come together and appeal ther to the courts nor to the tribunal.

Ir. HARDIE said that with the great development in lical science to-day men in that profession had to have kinds of electrical and other apparatus, special kinds of hs and lights. In the same way as the ordinary iness man they ought to come under this Bill for any d or bad that was in it.

fter further debate,

he Bill was read a third time by 149 votes to 64.

MONDAY, NOV. 21ST.

Closing of Pensions Hospitals.

Ir. ERNEST BROWN asked the Minister of Pensions ch hospitals had been closed during the four years ing Oct. 31st, 1927; how many ex-Service orderly staff were ineligible for unemployment benefit had been harged; whether it was proposed to close any more oitals during the next financial year; and, if so, how ny ex-Service orderly staff would be discharged without other assistance than that of the local guardians.—t.-Colonel STANLEY (Parliamentary Secretary to the istry of Pensions) replied: The number of Ministry oitals (including treatment and training centres) closed ng the four years ended Oct. 31st, 1927, was 19, and number of ex-Service orderlies ineligible for unemploy- t benefit thereby discharged was approximately 470. ar as can be foreseen at present, three hospitals will be ted by accommodation changes contemplated during next financial year. The net total reduction of ex-Service rlies ineligible for unemployment benefit will probably exceed 30.

Old Age Pensioners and Medical Treatment.

r. GROVES asked the Secretary to the Treasury whether old age pensions were paid to persons who at be in receipt of medical treatment extending over a th in a Poor-law institution; and whether such pension, yable, should be collected by the next legally responsible on to the ordinary recipient; (2) whether he was re that during the week ended July 6th, 1917, 117 old pensioners, who were inmates of various institutions r the West Ham Board of Guardians, had their pensions cted by the said board and applied toward the cost of maintenance whilst in receipt of medical treatment; whether, in view of the provisions of the Old Age ions Acts, he would prohibit this practice.—Mr. A. M. UEL replied: A person who enters a Poor-law institution he purpose of obtaining medical or surgical treatment ot thereby disqualified for the receipt of an old age ion until three months from the date of his entry into institution, if he continues to receive such treatment ng that period. It is a fact that the West Ham Board guardians, in common with some other boards of dians, collect the pensions of inmates of their insti- ons; but in every case the pensioner has signed a form inting an officer of the guardians as his agent to collect pension, and there is no authority in the law under h such a practice could be prohibited.

Insured Persons and Specialist Medical Service.

r. HORE-BELISHA asked the Minister of Health whether ad now received the recommendations of the consultative cil regarding the proposals made by the Royal Com- ion on National Health Insurance that the scope of benefit should be extended to include a consultant and alist medical service, and that the necessary funds for purpose should be obtained by a partial pooling of e surpluses of approved societies; and what action it proposed to take.—Sir KINGSLEY WOOD replied: My hon. friend has now received the views of the con- tive council on the proposals referred to by the hon. ber, and they are having his most careful consideration, he is not yet in a position to make any statement on matter.

The Indian Medical Service.

r. SPOOR asked the Under Secretary of State for India ther he was aware that at a selection test held in August in India, to select candidates for permanent com- ions in the Indian Medical Service, only those candidates ing an English degree were successful; whether, in of this fact, instructions had been issued by the tary of State that those candidates who possessed an medical qualifications alone were unfit for per- nt commissions in the Indian Medical Service and that for this an English degree was necessary; and whether, in view of the recommendations of the Indian Students' Committee presided over by Lord Lytton in 1921, he could state the position of the Government of India and His Majesty's Government in the matter.—Earl WINTERTON replied: The answer to the first part of the question is in the affirmative and to the second in the negative. Candidates who possess the necessary qualifications prescribed by the regulations, whether they have been obtained in India or in this country, are selected strictly on their merits. As regards the third part of the question, I am not aware of any definite recommendation made by the Committee on Indian students on this subject. I can, however, assure the right hon. gentleman that every effort is being made to improve the standard of medical teaching in India.

Mr. WILFRID PALING asked the Under Secretary of State for India whether it was the policy of the Government of India and of His Majesty's Government to recruit candidates to the Indian Medical Service from Europeans rather than from Indians; and whether he was aware that the expense to the Indian taxpayer was very much heavier in the case of European than in the case of Indian medical men.—Earl WINTERTON replied: Recruitment for the Indian Medical Service is carried out strictly on a ratio of two Europeans to one Indian. This in present conditions has the effect of increasing the number of Indians in the Service. All officers draw the same rates of pay, but those of non-Asiatic domicile receive certain benefits to compensate for permanent service abroad. The additional expense in the case of the European officer is relatively small.

TUESDAY, NOV. 22ND.

Medical Practitioners' Privilege.

Dr. E. GRAHAM LITTLE, in asking leave to introduce the Medical Practitioners' Communications Privilege Bill, said that it was a measure which was intended to remove something like a deadlock which had resulted from a conflict between the regulations issued by a Government department in 1916, and the law as interpreted by certain recent legal decisions. In 1916 the Royal Commission on Venereal Diseases issued its report. Its personnel was admirably authoritative and representative. It included Mr. Philip Snowden, who had done him the honour to put his name on the back of this Bill. Unhappily there was a popular belief that venereal disease was a special order of disease resulting from excessive indulgence in a normal function, that this disease deserved punishment, and that people got it in some mysterious way which differed from other disorders. That view had never been held by the medical profession, and he hoped that it was out of date in this country. In practice venereal disease led to two dissimilar effects—syphilis and gonorrhœa. The report of the Royal Commission showed an unexpectedly high percentage of both diseases in this country. It was established by the evidence given before the Commission that syphilis ranked third as a killing disease, coming after cancer and tubercle. Perhaps it ought to come first, because in many cases it produced the two other diseases. Besides being very mortal, particularly among young children, slaying tens of thousands of victims, it was, with its companion diseases, easily the first of all the disabling diseases known to-day. Syphilis, in particular, was primarily responsible for a large proportion of cases of insanity, and for a long string of diseases of the nervous system which made life a prolonged agony. Evidence was given in the report of the Commission that at least one in every ten persons in our community were affected, and more than half the total number of cases of blindness in young children was due to this curse. The medical position of these cases might be summed up in an epigram of a medical man: "Who knows all about venereal diseases knows all about medicine, because they affect every organ and tissue of the body." The state of affairs disclosed by the report of the Commission was so appalling that immediate action was called for, and was happily taken. In consequence and pursuance of the recommendations of the Commission the Local Government Board, in the same year as the report was published, inaugurated a system of clinics for the treatment of this disease throughout the country, and issued regulations for their conduct. The foremost and most important among these regulations was an instruction to medical practitioners and other persons concerned that all information obtained as regarded any persons treated in these clinics should be regarded as absolutely confidential. The evidence before the Commission demonstrated that it was necessary for the success of any measure for the treatment of venereal disease that the patient should be fully assured of secrecy. The reason was surely obvious. Modern methods of treatment had completely revolutionised the prognosis of this disease, and a condition was that early treatment should be instituted. Irreparable mischief might result, and had resulted, from the disinclination of the victims of the disease to consult their family doctor. The reasons for that were obvious.

It was almost impossible to have the disease treated at home, and to conceal its nature. But the same patient would go to a clinic, where he was identified only by a number, and where he knew that he would get the very best treatment that the medical science of the time could afford. Under the present rules patients went to the clinics and received explicit assurances that no information whatever concerning their disease would be divulged, and that assurance was fortified by the issue of a leaflet, in which the same promise was given, emanating from the Ministry of Health, and carrying with it therefore the authority of Parliament. The success of these clinics rested upon two factors—the enthusiastic coöperation of the medical practitioner in charge, and the complete confidence of the patient treated. That coöperation and that confidence had been abundantly won by the assurance of secrecy. Doctor and patient alike had felt secured by the ministerial regulations from any possibility of being compelled to make any disclosure of these confidential communications. But the security had been completely shattered by the decision, given in Birmingham last July, by Mr. Justice McCardie, when a doctor was ordered to disclose the character of the disease from which his patient was suffering, although he had acted under the explicit protection of the regulations framed by the Ministry of Health. Medical men thus found themselves forced to betray the trust of their patients, and he contended that that betrayal was really an affront to Parliament, because Parliament must be responsible in some measure for the acts of one of its most important Ministers. The position which the Bill sought to remedy was that complete privilege should be given to communications, which had been erroneously supposed for the last 12 years to be privileged. It was clear that either the law must be amended in the way he suggested or that the Ministry of Health regulations must be scrapped. He was encouraged by the opinion of eminent Members of the House that any legal difficulty could be readily overcome. If, however, the regulations were scrapped, the fate of a highly successful and important ministerial and medical effort was sealed.

The sponsors of the Bill were: Dr. Vernon Davies, Sir Walter Greaves-Lord, Mr. E. C. Grenfell, Mr. Arthur Henderson, Mr. F. B. Merriman, Mr. Hopkin Morris, Sir Basil Peto, Mr. Goodman Roberts, Dr. Salter, Mr. Snowden, and Mr. Storry Deans.

Leave was granted to bring in the Bill, which was then read a first time.

Women and Lead Paint Poisoning.

Dr. LITTLE asked the Secretary of State for the Home Department if, since Clause 2 of the Lead Paint (Protection Against Poisoning) Act, 1926, came into force on Nov. 19th, he had made an order under proviso (*b*) authorising women to do special decorative work and other work not being of an industrial character; had he received any representation from women affected by the Act urging the making of an order under Clause 2, proviso (*b*); and would he accede to the request to receive a deputation from women affected by the Act.—Sir W. JOYNSON-HICKS replied: In pursuance of the provisions referred to, I made an order on the 14th instant which will have the effect of allowing women and young persons to be employed in the execution of wall or ceiling paintings or in any similar work of decorative design. Notice of the order, which will be published as a statutory rule and order, has been given in the press, and other steps have been taken to bring it to the knowledge of all concerned. Previous to the making of the order representations in regard to it were received from certain firms of women decorators. The order desired by these firms, however, was of a much wider character than the Act contemplates, and it was impossible for me to give effect to their suggestions. As regards the last part of the question, I have been asked to receive a deputation to protest against the general prohibition in the Act against the employment of women in painting buildings with lead paint, and to press for legislation for the removal of this prohibition. Seeing, however, that the prohibition was enacted by Parliament, after full discussion, so recently as 1926, and that leave was refused in July last by this House for the introduction of a Bill to remove the prohibition, I am not prepared to reopen this question, and I regret therefore I do not see my way ot accede to the request.

OBSERVATION WARDS AT BOW.—The Mayor of Poplar has opened a new maternity and child welfare centre in Wellington-road, Bow. Observation accommodation for ten children is provided in two five-cot wards, with nurses' duty room and milk laboratory adjoining, along with an isolation ward; there are also well-equipped dental and artificial sunlight clinics. Dr. F. W. Alexander, medical officer for Poplar, expressed his belief that the time is not far distant when maternity clinics will all be fitted with diathermy machines.

Medical News.

UNIVERSITY OF LONDON.—At a meeting of Senate on Nov. 16th, Dr. J. A. Braxton Hicks was appoin as from Sept. 1st, 1927, to the University Readership Pathology, tenable at the Westminster Hospital Med School. Dr. Braxton Hicks has worked since 1910 in Department of Pathology at the School, and since laboratories were enlarged under the John Burford Ca bequest he has been their director. He is also bacteriolo to the City of Westminster, and consulting patholo to the West End Hospital for Nervous Diseases. A of 250 guineas has been received from Messrs. J. Lyons Co., Ltd., towards the establishment of the proposed Cl of Dietetics.

A course of five lectures on the Technique of Bacte logical Research will be given by Dr. F. W. Twort in theatre of the Royal College of Surgeons, Lincoln's Inn-fie London, W.C., on Dec. 5th, 7th, 9th, 12th, and 14th 4 P.M. Admission is free, without ticket.

UNIVERSITY OF GLASGOW.—The two vac assessorships in the University Court of Glasgow have filled by the appointment of Dr. David Murray and John Freeland Fergus.

ROYAL INSTITUTE OF PUBLIC HEALTH.—It is unc understood that next year's meeting of the Institute i be held in Dublin, probably in the month of August. committee has been appointed to make the necess arrangements.

ROYAL MEDICAL BENEVOLENT FUND GUILD.—T Duchess of York will attend the May Fair Ball to be at the May Fair Hotel on Thursday, Dec. 1st, at 10 P in aid of the educational work of the Guild, for w £3000 is urgently required. Further particulars may had from the hon. secretary, Miss Tweedy, 100, Har street, London, W. 1.

COLLEGE OF PESTOLOGY.—Under the chairmans of the President, Sir William Bull, M.P., the College Pestology (Incorporated) held its annual dinner on Tues last at the Connaught Rooms. The Maxwell-Lefroy medal, for the best essay of the year on pest destruct was presented by Dr. E. Graham Little to Miss Fa O'Riordan, for her treatise on the extermination of fl an oil-painting of the late Prof. Maxwell-Lefroy, prese by Miss Blanche Harvey, was shown in the dining-ro In proposing the toast of The Ladies, Mr. A. Moore Hoga the chairman of the College, spoke of the part of wome practical pestology, and Miss E. Prentice replied. Am the guests were Sir Thomas Horder, Dr. Leonard Hill, Leslie Scott, K.C., Sir Alfred D. Fripp, and Dr. G. C Trotter.

FELLOWSHIP OF MEDICINE AND POST-GRADU MEDICAL ASSOCIATION.—On Monday, Nov. 28th, at 5 at the rooms of the Medical Society of London, 11, Chan street, Cavendish-square, W., Mr. Harold Chapple give a lecture entitled Practical Hints in Gynæcology Obstetrics. On Friday, Dec. 2nd, at 2 P.M., at the Nati Hospital for Diseases of the Heart, Westmorland-st Dr. John Parkinson will give a clinical demonstra The lecture and the demonstration are open to mem of the medical profession without fee. From Nov. to Dec. 3rd, at St. Mark's Hospital for Diseases of Rectum, a post-graduate course in Proctology will be during the afternoons and some mornings, the course sisting of lectures, operations, out-patient demonstra pathological demonstrations, and ward rounds. F Nov. 21st to Dec. 17th, at 5 P.M., the West End Hos for Nervous Diseases is holding a course in Neurol From Dec. 5th to 17th, at 2.30 P.M. daily, at the Inf Hospital, Vincent-square, a special course, with lect and demonstrations, will be held, and between the s dates at the same hour a course in Dermatology will place at the Hospital for Diseases of the Skin, Blackfr consisting of instruction in the out-patient department special demonstrations. From Jan. 9th to 21st, at Prince of Wales's General Hospital, there will be a co in medicine, surgery, and the specialties, and between same dates a course in Diseases of Children at the Childr Clinic. Courses in Cardiology at the National Hospita Diseases of the Heart, and in Psychological Medicine at Bethlem Royal Hospital will also be held in January. general course of work, which may be started at any and for any period, may be taken throughout the y Information, syllabuses, and tickets, and specimen c of the *Post-Graduate Medical Journal*, may be had from Secretary of the Fellowship at 1, Wimpole-street, Lon W. 1.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The arenga Prize for 1927 has been awarded to Dr. Emil ren, Cincinnati, Ohio, for an essay on Drunkenness.

NNS OF COURT.—Among those called to the Bar Nov. 17thwas Mr. A. Spong, M.R.C.P., F.R.C.S., who was ed at Gray's Inn.

MAUDSLEY HOSPITAL.—Lectures and practical ses of instruction for the Diploma in Psychological icine will be given at this hospital from Jan. 4th onwards.

OCIETY OF MEDICAL OFFICERS OF HEALTH.—The ual dinner was held on Nov. 17th at the Piccadilly Hotel, E. H. Snell presiding in the absence of the President, James Wheatley. In welcoming Mr. Neville Chamberlain, Snell said that he was the fifth Minister of Health within t years, and had held the office longer than any of his lecessors. It would be a good thing if the Minister had ter security of tenure. After long experience as a iicipal official, Dr. Snell found increasing difficulty in nguishing the political proclivities of the parties.

r. Chamberlain said that even in these days no one ocated the reduction of expenditure on the preventive ical services, on which the health and prosperity of people were founded. For efficiency it was important ave the heartiest coöperation between the Ministry and M.O.H.'s on the one hand, and between the M.O.H.'s nselves on the other. The health organisation in adminis- ve counties rather lent itself to friction, but the various als must work together in the closest possible relation. r efforts would never bear the best fruit unless they the coöperation of the public as well, and he was glad the society had established a Central Council of Health cation, with a new magazine, *Better Health*, which ed to be admirably adapted for its purpose. After ring to the value of annual reports, both to the Ministry to the public, Mr. Chamberlain concluded by urging M.O.H.'s should do their part in research by analysing masses of facts in their possession. He instanced ination, the period of infectivity of scarlet fever, and alue of disinfection, as subjects for investigation.

rd Eustace Percy (President of the Board of Education) ratulated the society on having arranged a visit of cal officers from abroad. Nothing, he said, could be valuable than to strengthen these international links. ointed out that the medical services of the Board of cation and the Ministry of Health were unified at the e and should be unified as far as possible at the peri- y. The system of medical inspection at three periods hool life was almost complete, and the main task of future was the preventive treatment of children's ses and defects. This work was making great progress, n the two years from 1924 to 1926 the number of minor nts dealt with had risen from 576,000 to 665,000. g the same period the number of visual defects treated isen from 160,000 to 190,000, and of ear, nose and t conditions from 34,000 to 68,000, whilst 852,000 l cases had been treated in 1926, compared with 00 in 1924. The public seemed to fear that a vast of officials was being created; the facts were as vs. The so-called army of nurses amounted to one very 1000 children in elementary schools, 40 per cent. em being district nurses, 30 per cent. engaged in public h work, and less than 20 per cent. employed as school s alone. There was one school medical officer to every children. Of these officers, 30 per cent. worked part- only, 47 per cent. were engaged in other branches of c health work, whilst only 20 per cent. devoted their time to the schools. There was only one dentist to 8000 children, and 50 per cent. of them were appointed part-time basis. These figures showed (1) that the was not extravagantly large in relation to the work done; (2) that the services of general practitioners being widely utilised; and (3) that public health and l work were often combined.

The Chairman, speaking of the rôle of the new Central cil of Health Education, said that many of the present educational societies could be swallowed up in an quake without harm to the community. It was clear nothing so needed reform as other people's habits. deal of the Council was to produce a journal free from s and fads. Dr. Snell ended an amusing speech by ing to the constant complaints of the Ministry that strict did not contain the proper quota of the blind, alt, and the mentally defective. Prof. Bostock Hill sed the health of the guests, and the Dean of West- er, Dr. Foxley Norris, who replied, spoke of the way ich the health services had taken over work previously by the Church. Prof. W. Silberschmidt, replying half of his foreign colleagues of the course of hygiene, ssed a high opinion of public health work in England. was a place for friendly rivalry between the nations, e family of medical officers should be international.

WE regret to announce the death of Dr. J. P. Purvis, treasurer of the West Kent Medico-Chirurgical Society.

STAFF OF PRINCESS LOUISE KENSINGTON HOSPITAL FOR CHILDREN.—The out-patient department of this hospital will open on Dec. 6th, and beds will be available for in-patients in the New Year. A formal opening ceremony is to be performed by the King and Queen next May if a further sum of £12,000 is raised before then to render this first portion of the hospital debt free. The following appointments to the consulting staff have been made: Consulting physician, Sir William Willcox; consulting surgeon, Sir Herbert Waterhouse; physicians, Dr. P. Montague Smith and Dr. Sydney A. Owen; surgeons, Mr. Neil Sinclair, Mr. R. M. Handfield-Jones, and Mr. Eric Lloyd; assistant physicians, Dr. Douglas Rice-Oxley, Dr. R. C. Lightwood, and Dr. Janet Aitken; assistant surgeon, Mr. Robert Paton; ear, throat and nose surgeon, Mr. G. Douglas Robertson; ophthalmic surgeon, Mr. A. E. Loosely; dermatologist, Mr. Lewes N. Gibbes; anæsthetists, Dr. Ernest F. Travers, Dr. Aileen Chester, and Dr. Audrey Phipps; medical officer in charge of electrical department, Dr. J. F. Carter Braine; radiologist, Dr. H. M. Worth; dental surgeon, Mr. L. Russell Marsh; pathologist, Dr. Robert Donaldson.

PROCEEDINGS UNDER THE LEAD PAINT ACT.—On Nov. 21st the first local case under the Lead Paint (Protection against Poisoning) Act, 1926, came before the Tunbridge Wells borough justices, when a firm of builders was summoned, as employers of persons engaged in painting, for not sending to the district inspector of factories the name and address of its office, contrary to the Act. Mr. C. B. Roos, H.M. Inspector of Factories, in conducting the prosecution, stated that, although not required by law to do so, the Home Office sent a letter on the subject to all employers, and also inserted notices in two trade papers. On Nov. 10th he visited the office of the defendant firm and inspected the time-sheets which showed that there were several men engaged on painting a house. A solicitor for the defence denied the receipt of a notice from the Home Office; and there was the further contention that the Act was obscure inasmuch as no time was provided for compliance with a particular section as was the case with other Acts of Parliament. The justices held that a technical offence had been committed, but as it was the first local case they decided that it should be dismissed on payment of costs. There was another summons against the same firm—for failing to keep for inspection by an inspector of factories at all reasonable times a register in prescribed form of persons employed in painting of buildings; but at the suggestion of the justices, in view of the Home Office object having been achieved in drawing attention to the requirements of the Act by way of the first summons, Mr. Roos withdrew this count. There was a plea of Not Guilty in each case.

IRISH MEDICAL SCHOOLS AND GRADUATES ASSOCIATION.—The autumn reunion of this Association was held at the Savoy Hotel on Nov. 17th, with Sir William Wheeler, the President, in the chair. There was a large assembly of members and guests, many ladies being present at what proved a very enjoyable function. After the loyal toasts had been drunk with musical honours, Dr. Lindsay Rea, in a happy speech, proposed "The Guests." Major-General Sir William Hickie responded and related many anecdotes about the deeds of Irish regiments during the war. He paid special tribute to the medical officers who served in the front line and with the field ambulances. Sir Bruce Bruce-Porter and Dr. William Hill also responded. Dr. Frederick Spicer proposed the toast of the President and Association. Sir William Wheeler, in reply, emphasised the importance of keeping and bringing Irish medical men together, and congratulated the responsible officers on the ever-increasing popularity of the Association. He referred to the admirable action of President Cosgrave's Government in establishing an Irish Medical Council which pleased everybody, in abolishing the union infirmaries, and in the setting up of machinery which would secure that appointments made to county hospitals should be no longer affected by local influence, but only by the real qualifications of a candidate for his job. There was an excellent musical programme, and the songs of Mr. Patrick Hughes and Miss Mabel Moore called for many encores. Miss Daci O'Niell acted as accompanist. One of the objects of the Association is to give opportunities for members to meet each other in pleasant circumstances, and the dinners, which are held in London twice a year, are well attended. The first takes place after the annual meeting on St. Patrick's Day, March 17th, whilst the second is held regularly on the third Thursday in November. The hon. secretary is Dr. F. R. Holmes Meyrick, 59, Kensington-court, London, W.8, to whom application may be made for membership.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Nov. 28th.—8 P.M., ODONTOLOGY. Mr. Bayford Underwood: Case of Pain and Swelling in Submaxillary Gland Caused by Pressure of Denture. Mr. Ivan S. Spain: The Uses of Nitrous Oxide and Oxygen in Dentistry.

THURSDAY, Dec. 1st.—8.15 P.M., TROPICAL DISEASES. Symposium on Technique by various speakers.

FRIDAY.—5 P.M., LARYNGOLOGY. (Cases at 4 P.M.). Discussion on Deep X Ray and Radium Therapy in Relation to the Mouth and Upper Respiratory Tract. Speakers: Dr. W. L. Watt and Dr. Finzi. Cases: Only cases bearing on the subject will be shown. ELECTRO-THERAPEUTICS: It is hoped that Members of the Section of Electro-Therapeutics will join this Discussion.—8.30 P.M., ANÆSTHETICS. Paper: Dr. T. P. Dunhill: Anæsthesia in Thyroid Surgery.

SATURDAY.—10 A.M., OTOLOGY. (Cases at 9.30 A.M.) Papers: Mr. Somerville Hastings and Mr. Gordon R. Scarff: Some Notes on Paracusis Willisii from the Ferens Institute of Otolaryngology. Dr. Dan McKenzie: Posterior (Mastoid) Drainage in Acute Suppuration of the Middle Ear. Cases: Dr. Russ Wood: Notes on a Case of Otitic Septicæmia. Dr. Leslie Powell: Case of Acute Otitis Media with very rapid Involvement of Lateral and both Cavernous Sinuses. Cases will also be shown by Sir James Dundas-Grant and others.

MEDICAL SOCIETY OF LONDON.

MONDAY, Nov. 28th.—8.30 P.M., Discussion on the Medical Society's Report on "The Late Results of Operation for Carcinoma of the Breast," introduced by Mr. T. P. Legg.

ROYAL SOCIETY OF ARTS, 1, John-street, Adelphi, W.C.

WEDNESDAY, Nov. 30th.—8 P.M., Prof. Henry E. Armstrong: Marcellin Berthelot and Synthetic Chemistry.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Nov. 28th, to SATURDAY, Dec. 3rd.—NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W. Special Clinical Demonstration by Dr. John Parkinson on Friday at 2 P.M.—FELLOWSHIP OF MEDICINE LECTURE, Medical Society, 11, Chandos-street, W. Mr. Harold Chapple on Practical Hints in Gynæcology and Obstetrics, at 5 P.M., on Monday, Nov. 28th. The above are free. ST. MARK'S HOSPITAL, City-road, E.C. Post-graduate Course in Proctology, occupying every afternoon and some mornings with Operations, Lectures, Out-patient Demonstrations, Pathological Demonstrations, and Wards.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Post-graduate Course in Medicine, Surgery, and Gynæcology. Afternoons and some mornings. Third week.—WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street, W. Post-graduate Course in Neurology. Every afternoon at 5 P.M. for four weeks. Further information from the Secretary, Mayfair 2236.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Nov. 28th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

There will also be a special demonstration of Surgical Cases on Monday, Nov. 28th, at 2 P.M., and of Eye Cases on Wednesday, Nov. 30th, at 2 P.M., by Mr. Ralph Coyte and Mr. N. B. B. Fleming respectively.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.

MONDAY, Nov. 28th.—2 P.M., Mr. Donald Armour: Operations. 2 P.M., Dr. Trevor Davies: Gynæcological Out-patients. 2 P.M., Mr. Addison: Surgical Wards.

Chief Inspector of Factories announces the following vacant appointment for Certifying Factory Surgeons: Maidstone (Kent).

Births, Marriages, and Deaths.

BIRTHS.

LE.—On Nov. 10th, at a nursing home, Dublin, the wife of Cecil D. Coyle, M.B., of a daughter.
LS.—On Nov. 18th, at West Bar, Banbury, the wife of Dr. C. J. L. Wells, of a daughter.

MARRIAGES.

NK—SHARP.—On Nov. 14th, at St. Stephen's, Hampstead, N.W., Herbert George Cronk, M.B., to Mary Sharp, late of Sarawak.
BURY—KAINES.—On Nov. 19th, 1927, at the Church of St. Mary-the-Virgin, Primrose Hill, N.W., by the Rev. Father Edward Wynn, O.G.S., Dean of Pembroke College, Cambridge, Lysander Montague Maybury, M.A., M.B., B.Chir. Camb., D.T.M. & H. Eng., eldest son of Dr. and Mrs. Lysander Maybury, of Southsea, to Florence Edna Kaines, daughter of Mr. and Mrs. H. Johnson Kaines, of Guernsey. Nuptial High Mass was sung by the Rev. A. S. Duncan-Jones, M.A., Vicar of St. Mary's, assisted by the Rev. Colin Dunlop, M.A., and the Rev. Leonard Williams, B.A.
CHESON—WALKER.—On Nov. 16th, at St. Mary Abbot's, Kensington, Victor S. Mitcheson, B.A. Camb., M.R.C.S., L.R.C.P., to Mildred Mary, only daughter of J. E. and Mrs. Walker, of Keswick.

DEATHS.

ELL.—On Nov. 18th, at 23, Nevern-square, S.W., George Cowell, F.R.C.S., Consulting Surgeon, Westminster Hospital, aged 92.
VIS.—On Nov. 18th, at "Thornhill," 16, The Grove, Greenwich, John Prior Purvis, M.R.C.S., L.S.A., in his 87th year.
TELOCKE.—On Nov. 19th, at Oxford, Richard Henry Anglin Whitelocke, M.D., F.R.C.S., in his 67th year.

—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

ENFORCEMENT OF VACCINATION LAWS IN COUNTY WEXFORD.

DEBATE IN THE DAIL EIREANN.

ON the motion for adjournment of the House on Nov. 24th Mr. M. J. JORDAN raised the question of the enforcement of the vaccination laws in County Wexford, arguing the case from the ratepayers' point of view. These laws had, he said, been in abeyance in the county for the last 20 years. There were now at least 17,000 defaulters, and the expense of serving notices and of doctors' fees would amount to £2550, apart from the cost at £5 per case of prosecuting, say, 5 per cent. of those who refused to comply.

General MULCAHY (Minister for Local Government and Public Health) asked the Deputy to develop the point as to who was going to bear the expense of an outbreak of small-pox if such should occur.

Mr. JORDAN: The fact remains that for the past 20 years the vaccination laws in Wexford have been in abeyance and no case of small-pox has broken out.

Sir JAMES CRAIG read a letter stating that £7,000,000 would be the price the British nation would have to pay during the year 1928–29 for dealing with small-pox if the present rate of increase were continued. Vaccination, he said, was in the nature of an insurance.

Dr. RYAN remarked that the big grievance in Wexford was that there was no conscientious objection clause, as there was in England. The people of Wexford were not prepared to see their children suffer. There was nothing political or what you might call antigovernment in the thing.

General MULCAHY said that he could not hold out any hope that he would not do everything possible to enforce the vaccination laws. The Free State was in the happy position since perhaps 1908 of having had only 11 cases of small-pox, and owing to the vigilance of the public health authorities these cases had been dealt with without the infection spreading. But during last year Britain had had 90 per cent. of the small-pox cases that existed in Europe and the danger of an extensive and dangerous outbreak spreading thence was serious. They had no assurance that the mild form of small-pox existing in any particular area would not develop into the virulent form, and it had not been suggested that the medical basis upon which the vaccination laws were framed was unsound. It had been argued that the administration of the laws in Wexford would cost a considerable amount, but the total legal expenses in New Ross since the urban district council had taken over from the guardians the administration of vaccination had only amounted, including 38 cases of default, to £21 14*s.* 7*d.* On the other hand, small-pox in Monmouthshire had already cost the ratepayers £10,000 in capital expenditure and equipment, while the maintenance of 200 beds for six months would mean another £13,000. There was no reason, if the danger were clearly shown, why the Wexford people should not be as sensible as any others. He could assure them that infantile vaccination was going to protect the children of the country up to the age of 12 years practically completely against the danger of small-pox. The Government had a duty to the people to prevent small-pox being brought over from England and developing in the country, and they were prepared to carry out that duty. "If there is a feeling," he said, "that there is not a sound medical basis to our present vaccination laws, we ought to have the position stated from the medical point of view. Do not let us act blindly in the dark because someone said antivaccination was always connected with the national movement in Ireland."

SICKNESS AND LIFE ASSURANCE FOR MEDICAL MEN.

AT the annual meeting of the Medical Sickness, Annuity, and Life Assurance Society, Ltd., on Nov. 14th, the chairman, Dr. F. J. Allan, was able to report that in spite of industrial disputes and influenza epidemics, the Society was in an improved position. That the medical and dental professions appreciated its soundness was evident, he said, from the fact that the premium income on the sickness fund was larger than the premium income of any other company doing permanent sickness insurance in this country. The Society endeavoured to treat its members fairly and he was pleased to say that it had never gone to law or even had to refer a claim to lawyers. The feature of last year's business had been that although the amounts insured were greater the actual new premiums were smaller because a large number of younger men had come in soon

after qualification and were therefore entitled to rebates on their first and second years' premiums.

Although medical men are constantly in touch with illness in persons of all ages, there are many who, especially when they are young, do not entertain the possibility that they themselves may become patients. That this view is short-sighted is shown by the fact that 24 per cent. of the Society's members come on the funds each year, whilst there are about 50 members who have been incapacitated for a long time, one of them having drawn benefit for 24 years. It is stated that in each year 19 out of every 1000 members undergo operation.

The Society's sickness fund at present amounts to £333,712, whilst only £245,071 is required to meet its liabilities. A new method has now been adopted for the distribution of the surplus, based on the complaint that a member may pay for sickness benefit for many years but never gets any cash return for his money unless he is ill. In the past the surplus has been distributed by offering a rebate to members on their annual premiums, but this has not proved wholly satisfactory, and in future the bonuses declared will be allowed to accumulate for the benefit of the member, and will be given him in a lump sum when he reaches the attainment age. Assuming that the Society's position is maintained, a man aged 30, who takes out a sickness policy for 5 guineas a week should receive a cheque for over £130 on closing the policy at the age of 65, besides any sums he may have drawn out in benefit in the interval. The advantages of the Society's life assurance policies may be shown by another example. A man aged 30, who effects a policy for £1000 payable at the age of 65, or at his previous death, will be asked to pay a premium of £25 6*s*. 8*d*. a year for 35 years—i.e., a total of £886. With income-tax rebate on the present scale the actual cost will be £798, but assuming that bonuses continue to be declared by the Society at the same rate he will receive at 65 the sum of £1350, which is equivalent to a return of all he has paid plus £552.

Of special interest to the young practitioner are the Society's schemes for assistance in the purchases of a house or a practice. The Society is in a strong position and is able to offer good terms in many directions because it caters only for the medical and dental professions (who are good clients from the point of view of honesty and health), and because its overhead charges are low.

ARTIFICIAL DEFORMATION OF THE SKULL.

To the Editor of THE LANCET.

SIR,—In my recent note on artificial cranial deformation (THE LANCET, Nov. 5th, p. 1001) I referred to an artificially deformed skull published in 1918 by Dr. G. Sobhy, but my attention has since been called to the fact that the gravest doubt must attach to the authenticity of that author's statements. He stated definitely that the skull was in possession of Dr. L. Gatineau, and that it was found in a tomb at Tell el Amarna (a statement which, if true, would definitely associate the skull with the reign of Akhenaten), but I have since ascertained that Dr. Gatineau himself afterwards published the identical skull as having been found by himself during excavations in a Coptic burial-ground of the Christian period at Medall, near Fachre, in Upper Egypt (La Semaine Dentaire, Jan. 22nd, 1922). I am endeavouring to ascertain the truth of the matter, but in the meantime I wish to withdraw any conclusions that may depend upon the authenticity of this skull. My original suggestion, however, that the heads of Akhenaten's children may have been deliberately deformed in imitation of their father's is not affected by eliminating from the discussion the skull mentioned above, for my note was intended to be no more than a tentative suggestion.

I am, Sir, yours faithfully,

WARREN R. DAWSON.

Palace Mansions, W., Nov. 19th, 1927.

PNEUMOCOCCI IN MICE.

IN a recent paper Dr. F. A. Coventry [1] has published the results of his investigation of the course of Type I. pneumococcal infections in mice by plating samples of blood at intervals. He considers that this method gives a more accurate record than that based only on survival time. In series of mice to which gradually increasing doses of whole Type I. antiserum and a constant dose of pneumococcal culture were injected simultaneously, plate cultures showed some bactericidal action on the organisms even when the survival time was not lengthened. As the dose of serum was increased alternate recurring zones of protection and partial protection were shown, but there were no zones of complete inaction as had been previously suggested. For example, with a constant dose of culture, 0·1 to 0·4 c.c. of serum (per 20 g. body-weight of mouse) completely protected the animals. Somewhat higher doses did not. Still higher doses—1·4 to 1·8 c.cm.—gave complete protection and doses above that showed protection in some cases but not in others. Similar results were found to follow Felton's concentrated antibodies instead of serum and also gave fewer cases of partial protection than did whole serum. Experiments on the curative action of concentrated antibodies in which the injection were made four hours after the dose of pneumococci showed that, although there was some initial inhibitory action in all cases, this was small with large doses (10 million M.L.D.) of pneumococci were used. When the dose was reduced, however, to 1 million M.L.D. complete protection was afforded by antiserum both in protective and curative experiments. No final explanation of these phenomena can at present be given, but the results are interesting in view of the fact that Type I. is the chief pneumococcus for which an antiserum of even moderate efficiency in man has been prepared. To have any effect in lobar pneumonia due to this type the serum must be given as early as possible, in large doses and preferably by the intravenous route. Until a means has been found of preparing this serum in a more concentrated form it is unlikely to become a common therapeutic agent.

[1] The Protective and Curative Action of Large Doses of Pneumococcus Antiserum in Mice. By F. A. Coventry. American Journal of Hygiene, Sept. 1927, vol. vii., No. 5, pp. 515–541.

NEEDLES FOR RECORD SYRINGES.

THE new "Summit" needle possesses distinct advantages. The old difficulty of having to thread the wire through a point has been overcome, and the wire can be passed easily from the cone end by means of a converging bore. The needle is so constructed that it cannot become dislodged from the cone, the junction being fluid-proof. It is easily picked up and held as the cone has concave surfaces. The needles are made in all the standard sizes and sold in packets of a dozen, fixed to a metal plate to prevent the point from being rubbed. The needles may be had from all surgical instrument houses. Details are obtainable from Messrs. Van Bros., Ltd., 3, Eden-street, London, N.W. 1.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—Recently my attention was drawn to an advertisement issued by a firm of manufacturing chemists, in which a passage from a paper published by me in the medical press was introduced in such a way as to leave the impression that one of their preparations was recommended by me. I had no knowledge of the preparation advertised, and the use of my name was entirely unauthorised. Following a protest made by me the quotation has been withdrawn from the advertisement, but the company decline to offer any apology for their action.

I am, Sir, yours faithfully,

DOUGLAS GUTHRIE.

Rothesay-place, Edinburgh. Nov. 21st, 1927.

*** Our correspondent is justly incensed at the employment of his name in any way that might give colour to the impression that he had behaved unethically.—ED. L.

A Retrospect OF DYSPNŒA.*

Y J. CRIGHTON BRAMWELL, M.A. CAMB., M.D. MANCH., M.R.C.P. LOND.,

TANT PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY, ND HONORARY ASSISTANT LECTURER IN EXPERIMENTAL PHYSIOLOGY, MANCHESTER UNIVERSITY.

HEN I selected dyspnœa as the subject for this re I was not aware that the "Causes and Treat- of Dyspnœa" had been the title of the first post- uate lecture ever given in the Manchester Royal mary. That lecture was delivered in the year by the late Dr. Daniel John Leech, who was our professor of therapeutics and senior ician to this hospital. My friend and colleague, Bosdin Leech, has kindly lent me the manuscript at lecture in order that I might compare the nt position of our knowledge on this subject that of 40 years ago.

e term dyspnœa implies not merely an increase e respiratory function, but a consciousness of increase on the part of the patient; or, as Dr. n expressed it, "dyspnœa is present when the *a de respirer* becomes apparent." The depth frequency of respiration in each one of us is nually varying, just as the force and rate of the -beat vary, in response to the requirements of oment. For the most part we are not conscious ese variations, and it is not until the lungs and begin to experience difficulty in meeting their ties that we suffer from dyspnœa or from ation.

with other subjective symptoms, a second plays a part in the production of dyspnœa—ty, the susceptibility of the perceptive nervous anism. At the end of the year's work, when we n down and in need of a holiday, most of us are o become unduly irritable and conscious of annoyances which at other times would pass iced. There is a class of unfortunate individuals, we speak of as hypersensitive, whose nervous n is always in this state. For them the threshold sciousness at which hyperpnœa becomes dyspnœa a lower level than in normal people.

healthy young subjects, during light and moderate ion, pulmonary ventilation increases in propor- o metabolism (Fig. 1), but when exercise is very ous, ventilation tends to increase more rapidly. n the region of this transition that the threshold pnœa is situated. The lowering of the threshold ersensitive subjects must be distinguished from rly attainment of the threshold under patho- conditions. In patients with congestive heart , for example, the pulmonary ventilation is ive, even at rest, and since on exertion it ses more rapidly than in healthy subjects, the old of dyspnœa is reached abnormally quickly.

CHEMICAL REGULATION OF BREATHING.

depth and frequency of respiration is controlled entre in the medulla, and the normal stimulus excites the respiratory centre is an increase acidity, or, to use the modern terminology, a n its hydrogen-ion concentration, The body raordinarily sensitive to minute changes of gen-ion concentration; in fact, only a very range of variation is compatible with life. Two , the kidneys and the lungs, are principally ned with maintaining the reaction of the blood the prescribed limits. The kidney is, so to the coarse adjustment which eliminates from stem in bulk the excess of acid or alkali as the ay be, while the lung is the fine adjustment, by varying the depth and frequency of respiration, can regulate the output of carbon dioxide in such a way as to maintain to a nicety the normal hydrogen-ion concentration. On account of its action on the respiratory centre, carbon dioxide is used therapeutically in carbon monoxide poisoning, and Yandell Henderson[4] has pointed out its value as a respiratory stimulant in anæsthetic practice.

When the kidney is diseased and fails to excrete the acids formed in the body, the readjustment of the acid base balance depends on an increase of lung ventilation. Consequently it is not surprising that dyspnœa is a prominent symptom in certain forms of nephritis. Similarly, in the condition known as ketosis, which is met with most commonly as a complication of diabetes and in association with starvation, abnormal acid substances are produced in the body from the incomplete combustion of fats. By increasing the hydrogen-ion concentration of the blood these ketone bodies provoke dyspnœa.

FIG. 1.

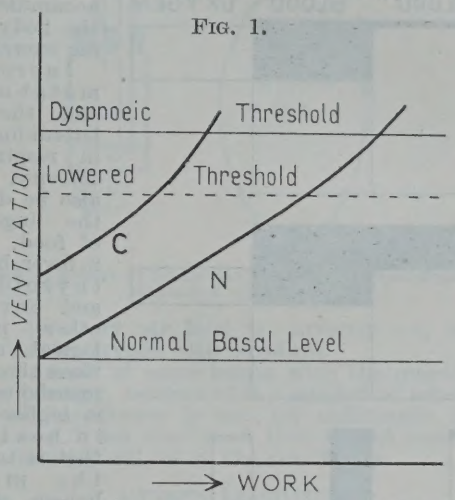

Diagram to illustrate increase of respiratory activity with work in normal (N) and cardiac (C) subjects, and the lowering of the threshold for dyspnœa when the perceptive nervous mechanism is hypersensitive.

It is interesting to note that 40 years ago the dyspnœa of nephritis and diabetes was attributed to an increased sensitivity of the respiratory centre. In fact, it was not until it was shown that carbon dioxide stimulated the respiratory centre by virtue of its acid properties that these two conditions were brought into line with the more familiar types of dyspnœa.

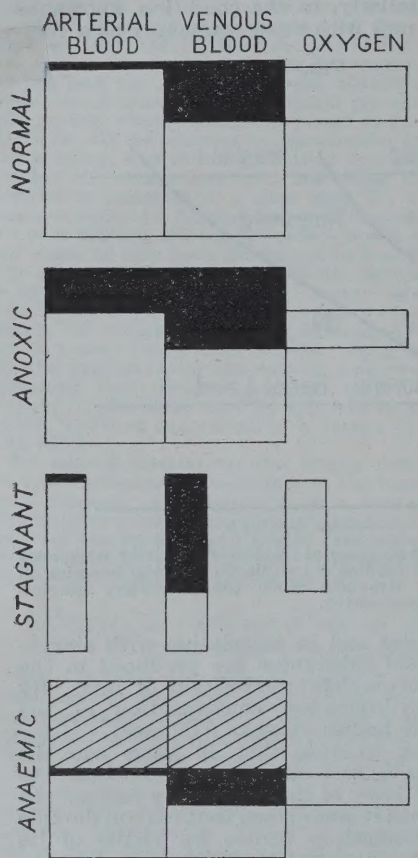
The essential factor, then, in the regulation of breathing is the hydrogen-ion concentration of the blood. The slightest bias towards the acid side stimulates the respiratory centre to increased activity and, if sufficient, will produce dyspnœa, while any change in the alkaline direction leads to a diminution of lung ventilation. There is, however, an additional factor to be considered—namely, the oxygen content of the blood. Oxygen-want renders the respiratory centre unduly sensitive to the chemical stimulus by which it is normally excited—namely, the hydrogen-ion concentration of the blood circulating through it. In people living at high altitudes, for example, the respiratory centre will not tolerate such a high tension of carbon dioxide in the alveolar air as it does at sea-level, and this is one reason why in them dyspnœa is more easily provoked.

Under normal atmospheric conditions, healthy young people, in good physical training, rarely suffer from dyspnœa, except during and immediately after violent exertion. We now know[5] that the actual process of muscular contraction is entirely anaerobic and depends on the conversion of glycogen into lactic acid with the liberation of energy. This is followed by what is called the "recovery phase," during which the lactic acid is disposed of, partly by oxidation to carbon dioxide and partly by reconversion into glycogen. During exercise the contraction and recovery processes are taking place concurrently;

* t-graduate lecture delivered at the Manchester Royal ry on Sept. 27th, 1927.

and so long as the removal of lactic acid keeps pace with its production, an equilibrium is established and exercise can proceed. As soon, however, as the oxygen supply becomes inadequate to provide for its oxidative removal the lactic acid begins to accumulate in the tissues, and, as A. V. Hill and his co-workers[5] have expressed it, the body "goes into debt" for oxygen. The panting which follows the cessation of exercise in human beings is necessary to pay off this debt, by supplying sufficient oxygen to provide for the removal of the excess of lactic acid which has accumulated in the body during exercise.

FIG. 2.



Types of anoxæmia. Ordinates represent percentage of hæmoglobin, white = oxyhæmoglobin, black = reduced hæmoglobin. Abscissæ represent blood flow. Hence white and black rectangles represent minute volume of oxy- and reduced hæmoglobin respectively in arterial and venous blood.

Increased metabolism, and the collateral increase in respiratory activity, may also be due to the ingestion of food, while in fever, hyperthyroidism, and certain other pathological conditions the basal metabolic rate is higher than in health—that is to say, the metabolism of the body is increased even at rest and while fasting. Consequently, under all these conditions, when physical exertion is superadded, the threshold of dyspnœa is reached more quickly.

Anoxæmia.

The amount of oxygen available for the tissues is determined principally by two factors: (1) the quantity of blood flowing through the tissues per minute (i.e., the circulation-rate), and (2) the oxygen content of that blood. To maintain an adequate circulation-rate is the business of the heart, while the oxygen content of the arterial blood depends on (1) the oxygen tension in the alveolar air, (2) the ability of the lung to allow the oxygen to pass into the blood, and (3) the hæmoglobin content of the blood. Barcroft has accordingly classified the various types of anoxæmia into three groups.

1. *Anoxic*, in which the pulmonary mechanism is primarily at fault and the arterial blood is not fully oxygenated. This may be due to a low tension of oxygen in the alveolar air, such as occurs at high altitudes, to some gross obstruction in the respiratory passages, or to an actual lesion of the lung itself, as in pneumonia or irritant gas poisoning.

2. *Stagnant*, in which the arterial blood is fully oxygenated, but the circulation-rate is too slow to provide an adequate blood-supply to the tissues. Heart failure is responsible for these cases.

3. *Anæmic*, in which the hæmoglobin content of the blood is reduced to such an extent that, even when the circulation-rate is normal and when the blood, such as it is, is fully oxygenated in the lungs, the quantity of oxygen which it is capable of carrying is insufficient for the requirements of the body.

I have attempted to illustrate these three types in a purely diagrammatic fashion (Fig. 2) by representing the total quantity of oxy- and reduced hæmoglobin in the arterial and venous blood respectively. The rectangles on the right of the diagram illustrate the difference between the arterial and venous blood—i.e., the quantity of oxygen abstracted by the tissues.

OXYGEN THERAPY.

My reason for referring to the different types of anoxæmia is to point out that it is only in anoxæmia that the arterial blood is not fully saturated with oxygen in passing through the lungs, and consequently it is only in those cases of dyspnœa which fall into this group that we are likely to obtain real benefit from oxygen therapy. I do not wish to suggest that, in cases of dyspnœa due to either of the other two types of anoxæmia, oxygen therapy is entirely useless, for by increasing greatly the oxygen tension in the alveolar air we can increase the amount of oxygen carried in solution in the plasma, though not the amount which is in chemical combination with hæmoglobin.

There are two conditions in which defective saturation of the hæmoglobin in the arterial blood will be relieved by oxygen therapy. In certain congenital heart lesions part of the blood is shunted directly from the right to the left heart without passing through the lungs, while in pneumonia that part of the blood which passes through the capillaries of the hepatic lung reaches the left auricle in an unoxygenated state.

It is important to remember, however, that in particular case there may be more than one factor involved. Profound anæmia, for instance, is frequently accompanied by fatty degeneration of the heart; while in congestive heart failure the reduced cardiac output is often complicated by œdema of the lungs; and in so far as the dyspnœa is due to impeded aeration of the blood from this cause, relief may be expected from oxygen therapy. Even in the early stages of heart disease there is a pulmonary factor involved in the production of dyspnœa, for, as Peabody has shown, the vital capacity (i.e., the maximum ventilation per breath) in these patients is reduced owing to impairment of elasticity of the lungs resulting from pulmonary congestion. Still another factor which contributes to the production of dyspnœa in cardiac patients is their increased basal metabolism, and I am inclined to think that, in some cases at any rate, there may also be an element of bronchial spasm, for I have sometimes seen benefit obtained from hypodermic injections of adrenalin, which strongly suggests an analogy to true spasmodic asthma. In conditions such as pneumonia, cyanosis is generally regarded as the principal clinical indication for the therapeutic use of oxygen. It is, however, important to remember, as Lundsgaard and Van Slyke[7] have pointed out, that general cyanosis does not appear until the hæmoglobin of the arterial blood is less than 85 per cent. saturated with oxygen. Since the normal saturation of the arterial blood is 96 per cent., and the threshold of cyanosis is about 85 per cent., a degree of anoxæmia probably sufficient to damage, at any rate, the more sensitive tissues such as those of the central nervous system, is already present before cyanosis appears. The aim of oxygen therapy should therefore be to prevent, and not merely to abolish, cyanosis.

Dr. Daniel Leech, in his lecture on the treatment of dyspnœa delivered in 1890, did not even refer to oxygen therapy. I have no doubt that the reason for this omission is that he did not consider the subject of sufficient practical importance to be worth mentioning. The pharmacologists at that time had not realised its possibilities, whilst the clinicians were naturally dissatisfied with the results obtained by the methods of administration then in vogue. It was not until 1915, when the treatment of soldiers suffering from chlorine gas poisoning became a problem of the utmost urgency, that a notable advance was

he technique of oxygen administration by J. S. lane's[3] introduction of the closed mask method. aim of oxygen therapy is to increase the partial sure of oxygen in the alveolar air. Judged by the only true criterion, the method of delivering gen from a funnel suspended at a distance of some es from the patient's face, is absolutely useless. ful measurements[2 6] show that the old open iod is incapable of producing any appreciable in the oxygen tension in the alveolar air, unless funnel be actually in contact with the face, and even so the results compare unfavourably with e obtained by means of a nasal catheter or a d mask. Even if the funnel had been capable elivering the oxygen to the lungs, the rate at h it was given by the open method rarely exceeded e per minute, whereas about eight times this rate w is usually necessary. As Davies and Gilchrist[2] pointed out, any apparent benefit which accrued such a parsimonious dose can only be attributed e psychotherapeutic effect.

om the point of view of the patient's comfort, the method of raising the alveolar oxygen tension place his bed in a closed chamber in which xygen content of the air breathed can be raised ie required concentration. The expense, how- of the apparatus renders this method extremely ed in its application. I do not therefore propose scuss it further, beyond saying that a modifica- of this method—namely, the "oxygen tent"— ed at the Mayo Clinic and elsewhere, brings it n the scope, at any rate, of hospital practice: a miniature oxygen chamber, the "oxygen has been designed by Raper[1] and used with ss in the treatment of marasmic infants.

ere remain the various types of oxygen mask he nasal catheter, both of which fufil the funda- al requirement of raising the alveolar oxygen on. The nasal catheter method is perfectly actory in many cases, but when it is necessary tain a high concentration of oxygen in the lar air, the rapid rate of flow entails considerable nfort to the patient. The drawbacks of the are obvious. A dyspnœic patient will not the idea of having anything put over his mouth ose which may still further hinder his embar- breathing. In this connexion there is a prac- point worth noting. When the mask is first d the patient is apt to take a very deep breath. encounters any undue resistance, or if with this reath he merely takes in air instead of the n-enriched mixture, his discomfort will be sed and he will probably refuse to give the a further trial. To overcome this difficulty, s and Gilchrist have introduced a modification ldane's original apparatus, attaching a reserve about 5 litres capacity to the mask, and filling h oxygen before the mask is applied. This is nt to satisfy the patient's requirements; his gasp will bring relief instead of producing onal discomfort, and he will be encouraged ceed. In Davies and Gilchrist's apparatus v-meter attached to the cylinder serves to te the volume of pure oxygen in litres inute which the patient is receiving, while ldditional adjustable air inlet in the mask s the operator to dilute the oxygen with the ed quantity of atmospheric air. The general ure with Davies and Gilchrist's modification ldane's instrument is first to set the reducing on the oxygen cylinder so that it delivers the ed quantity of oxygen per minute to the reserve nd then to vary the aperture of the accessory let in the mask until the volume of oxygen into the mask from the reserve bag during tion is approximately equal to that flowing uously from the cylinder into the bag during hole respiratory cycle.

e in many pathological conditions oxygen istration must be continuous over considerable s of time, the question of cost becomes impor- and economy has been considered in designing the more modern types of apparatus. It is obvious that it is only during the inspiratory phase of respiration that oxygen can serve any useful purpose, and that at least half the oxygen will be wasted if the supply to the mask be continuous. In Davies and Gilchrist's instrument (Fig. 3) there is a water valve which serves a threefold purpose. It automatically cuts off the oxygen-supply during expiration, it serves as a tell-tale to indicate whether the aperture

FIG. 3.

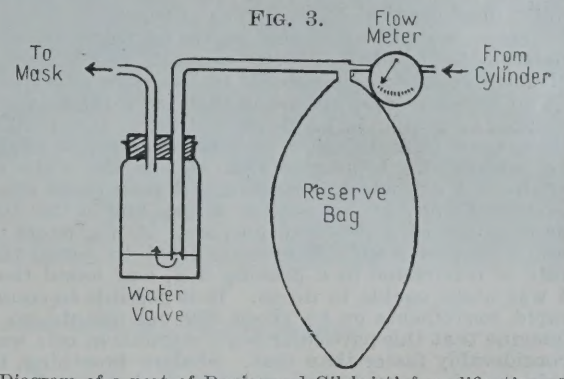


Diagram of a part of Davies and Gilchrist's[2] modification of Haldane's apparatus.

of the accessory air inlet is correctly set, and it saturates the oxygen with moisture.

I have dealt at some length with the question of oxygen therapy, because it is a subject of which the practical importance is not yet sufficiently appreciated, and I am convinced that it will come into much more general use in the near future.

OXYGEN LIABILITY.

Disease in its various mainfestations continually brings us face to face with the economic problem of supply and demand. When the demand of the body for any particular commodity exceeds the supply, symptoms of distress supervene. The relief of those symptoms depends on the restoration of the normal balance, and that may be brought about in one of two ways, either by increasing the assets of the body, or by reducing its liabilities. In dyspnœa we increase the assets by the administration of oxygen. Let us now see how we can reduce the liabilities.

Except in those conditions, such as diabetes and nephritis, in which dyspnœa is directly attributable to an acidosis, and the purely functional cases of nervous origin to which I shall refer later, pulmonary ventilation varies with metabolic activity. By reducing metabolism, therefore, we can diminish the liabilities. Consider, for example, the beneficial effect of rest in cardiac dyspnœa. An attempt to make a badly damaged heart increase its output is unlikely to be successful, but by reducing the demand for oxygen until it no longer exceeds the supply, the normal balance may be restored. Indirectly, by resting the heart muscle, we enable it to recuperate, and so not only diminish the patient's liabilities but also increase his assets. In pneumonia the beneficial effect of opium derivatives in relieving dyspnœa is in part attributable to diminished metabolism, through the abolition of restlessness; morphia is also a most useful drug in cardiac dyspnœa. In urgent cases of severe heart failure with auricular fibrillation I have often obtained most dramatic results by giving morphia hypodermically, in conjunction with massive doses of digitalis; and I am convinced that, by ensuring a period of much-needed sleep, the morphia played an important part in improving the condition of these patients.

The reputation of opium rests primarily on its power to relieve pain. The pleural pain so commonly associated with pneumonia is responsible for limiting the movements of the thorax and producing shallow breathing, and, as the depth of respiration diminishes, its frequency has to increase, even to a greater extent than is at first sight apparent. The reason for this

is as follows. A considerable portion of the air which enters the chest with each respiration remains in the "dead space" formed by the trachea and bronchi, and never reaches the alveoli of the lung. The tidal air (i.e., the amount of air which passes to and fro through the larynx with each breath) during quiet respiration amounts to about 500 c.cm. Of this some 150 c.cm. are required to fill the dead space. Supposing then, for example, that in shallow breathing the tidal air only amounts to 250 c.cm., 150 c.cm. still remain in the dead space and only 100 c.cm. reach the alveoli. In other words, when the depth of respiration is reduced to one-half of the normal, the effective alveolar ventilation is reduced to less than one-third. In an extreme case, supposing that the tidal air were reduced to a quarter of its normal value (125 c.cm.), then, apart from diffusion, only the dead space would be ventilated. I imagine that this is the state of affairs in a dog which is panting. A man pants after exercise to pay off his oxygen debt; but in the dog panting serves a different purpose. A dog pants in order to cool itself. I recently tried to count the rate of respiration in a panting dog, and found that I was quite unable to do so. It is possible to count rapid movements up to about 300 per minute, so I imagine that this particular dog's respiration-rate was considerably faster than that. Shallow breathing, in this case, is a necessary protective mechanism, for, if the dog were to take 400 full breaths per minute, it would in a few seconds reduce the tension of carbon dioxide in the alveolar air to such an extent that the respiratory centre would produce a complete inhibition of respiration—the condition which we speak of as acapnia. Similarly, the functional dyspnœa of nervous origin is so shallow that it fails to produce over-ventilation of the lung alveoli. In this connexion I might point out that shallow breathing is not only a cause but also one of the symptoms of anoxæmia. Hence a vicious circle is established which tends to aggravate the condition. Now, by relieving the pleural pain of pneumonia with morphia we increase the depth of respiration and improve the alveolar ventilation, and so help to relieve the dyspnœa.

The therapeutic use of alkalis in the relief of those forms of dyspnœa associated with acidosis may give temporary relief in nephritis; and, in some instances, the ketosis of diabetes has been found to yield to alkali and insulin when insulin alone was ineffective, but these observations are perhaps of academic interest rather than of great practical clinical importance.

Stimulation of the respiratory centre provides another theoretical possibility for the relief of dyspnœa. At first sight it might seem paradoxical to endeavour to increase the ventilation in cases of dyspnœa; but, from what I have already said, it will, I think, be apparent that we aim at increasing the depth and not the frequency of respiration. To this same mechanism I am inclined to attribute the relief which can sometimes be obtained in the paroxysmal type of cardiac dyspnœa from inhalation of the fumes of an ordinary ammonia smelling-bottle.

In this lecture I have merely touched on the fringe of a big subject. But I shall be satisfied if I have made it clear that we are progressing, not merely in unravelling the complex mechanism of dyspnœa from the scientific aspect, but also in the application of our new knowledge to the rational treatment of disease.

SUMMARY OF RESULTS OF EXPERIME ON THE PROPHYLAXIS AND TREATMENT CHILDHOOD GOITRE

IN HEANOR, DERBYSHIRE.

BY P. H. J. TURTON, M.D. EDIN.,
PHYSICIAN TO ILKESTON HOSPITAL AND HEANOR MEMOR HOSPITAL.

THE urban district of Heanor is situated i south-east of Derbyshire, on the southern end c coalfield. Its total population is approximately 2 It is a busy industrial area, the chief occupations coal mining, iron founding, and hosiery and manufacture. The district is hilly in all parts highest point being situated on Codnor Commo comprises Heanor, Marlpool, Langley, Langley Milnhay, Aldercar, Loscoe, and Codnor; all places have a common water-supply and no h now obtain their water-supplies from wells.

Water-supplies of the Area.

Before the introduction of the present supp 1902 the whole area depended upon surface wel the bulk of its water; there was also a local supply of bad quality, intermittent and t inadequate for the needs of the people. present supply is obtained from two sou viz.: (1) deep springs in the carboniferous lime in the vicinity of Wirksworth, 12 miles north-w Heanor; and (2) from two boreholes in the mil grit in the Derwent Valley close by the waterwo High Peak Junction, near Whatstandwell. The of the supply is obtained from the former (seven parts to three parts of borehole water). *limestone water is certainly liable to pollution*, b borehole waters are of exceptional purity (Ta A, B, C).

The softened water (Table I. (B) was turbi opaque, from the presence of white suspended consisting mainly of $CaCO_3$. The softened and fi water was clear and slightly greenish-yellow in c The softened water was decidedly alkaline fro presence of CaOH, whilst the softened and fi water was slightly alkaline from the presence of

The waters from the boreholes are of very s character and there is no indication of pollution free ammonia is of mineral origin. The waters free from lead and are satisfactory for d purposes. The analyses were made by Mr. White, the county analyst.

The water at the consumers' end is frequen spite of softening, carbonating, and filtering *turbid from the presence, as suspended matter, of c carbonate, in a very fine state of subdivision.* present time the water is softened with lim carbonated. There are not as yet a sufficient n of filters in use to deal with the total quantity of consumed. The water contains eight parts of per billion, the iodine content being among highest of any water-supply examined in Derb

Goitre has been endemic in this area for gener It was and is exceedingly common, though less in its endemicity than in days gone by. I have the above particulars, as those who are esp interested in goitre problems will appreciate significance.

Experiments with Iodised Sweets.

During 1926 a series of observations was carri by me in several schools in the Heanor Urban D on the effect of varying doses of iodine (as s iodide) upon the prevention and treatment of in children in the age-groups 8 to 17 years (incl The iodine was administered in the form of scotch sweets, each sweet containing the *equ* of 1/10th of a grain of iodine as sodium iodide. sweets were proved to be of standard streng analysis. In every case the written consent

ent was obtained before any treatment was plied.

Each child was first examined in the following nner :—

1) *Inspection of the Neck.*—The standard adopted s to include as goitrous any child whose thyroid at the final examination an allowance was made for natural increase in the size of the neck (for six months, 1 cm.; for 1 year, 1½ cm.).

(3) In a large number of cases photographs were taken before and after the experiments. This was found to be unreliable as a means of checking observations.

visible on inspection, so as to cause an alteration he contour of the neck.

) *Measurement of the Neck.*—In the case of every ous child the neck was measured before and after experiments, from the tip of the seventh cervical e behind to the centre of the neck in front at the of the cricoid cartilage. In measuring the necks

Approximately half the children of each age were given iodised sweets, the remainder acting as controls. With the exception of the children seen at Codnor, who were specially selected and were few in number (24), the total number of children examined at the five schools was 925, of whom 663 were girls (aged 8 to 17) and 262 were boys (aged 8 to 13). A large

number of those who left school before the completion of the experiments are not included in the returns (Table II.).

Normal.—In two of the groups (Nos. 2 and 3) the percentage of increase in size (i.e., those who developed visible signs of enlargement of the thyroid) amongst those untreated is greater than amongst those who were treated. In the three remaining groups, however, the position is reversed, where the percentage of increase in size is greater amongst those treated than in those who were *not* given iodine. The excess percentage of " increase in size " of the treated over the untreated is in one case as much as 10·8 per cent. The conclusion I draw from these results is that normal children in this goitrous area are, on the whole, better without iodine, even in small amounts.

Goitrous: (a) Increased in Size.—Amongst those who were treated with iodine the percentage of goitres which actually increased in size is in excess of the percentage of those which increased in size in four groups of those which were untreated (Nos. 1, 2, 4, and 5). In group No. 3 (boys) there were more which increased in size amongst the untreated than amongst the treated.

(b) Decreased in Size.—In a large number of instances those who were marked as having " decreased " were found to have lost their goitres entirely. This was the case both in those who were given iodine and in those who received no iodine. The remarkable fact is that as many as 47·5 per cent. of goitres in childhood disappear or decrease in size spontaneously. I have observed this tendency before in many children; McCarrison has done the same. In forming an opinion regarding the value of iodine in the treatment of childhood goitre insufficient notice has been taken by many people of this tendency to spontaneous disappearance. There is little doubt that many of the alleged cures following the use of iodine would have happened without it. In four of the groups (Nos. 2, 3, 4, and 5) there is an *excess* of percentage of those which decreased in size amongst those who were not treated over those who were treated with iodine.

Conclusion.

The observation of a large number of school-children over periods ranging from 6 to 12 months proves, in this particular goitrous area, that a large number of goitres seen between the ages of 8–17 either decrease in size or disappear entirely without the aid of iodine. The results of treatment of cases of goitre show that, whatever their cause may be, deficiency of iodine cannot be the cause, on account of so many being adversely affected.

In this connexion the recent work of R. McCarrison[1] proving that diets defective in their vitamin content, and, in particular, vitamin B, are capable of causing goitre of a type hitherto unproduced experimentally and in no way related to iodine intake is illuminating.

Whilst no actual harm has been observed in any individual child the good which has been done in those who responded favourably is overbalanced by the considerable number of those whose goitres have reacted unfavourably to the treatment. In other words, both the prophylaxis and treatment of goitre with iodine is not to be recommended as a general measure. It is not difficult to cause considerable distress with iodine, and as far as treatment of goitre is concerned this is a matter either for clinics or the attention of individual doctors.

The administration of the *equivalent* of 5 gr. of iodine as sodium iodide during two periods of five weeks each within six months would be deemed by many to be sufficient to prevent the onset of any goitre in those receiving it, but in spite of this amount over 31 per cent. of girls developed goitre during the period of observation.

Much smaller amounts of iodine as iodide have been claimed not only to prevent goitre, but to do many other things as well. I have not observed that inhabitants of Derbyshire are in any way thic headed than the inhabitants of other counties, th their necks may be thicker; indeed, it is by no m unusual to find children with quite large goitres are sharp, intelligent, and well developed. In n instances the goitres seen in children are nothing than physiological swellings, and it is an impertin to interfere with them.

It is perhaps worth recording that at the examinations I took pains not to know which chil received iodine or which child had been untr until the examination of the school had been pleted.

I acknowledge with pleasure my indebtedne Dr. W. M. Ash, the county medical officer of healt Derbyshire, for permission to publish the figures in this paper.

TYPHOID CARRIERS IN WESTER NORWAY:

RESULTS OF CHOLECYSTECTOMY.*

BY MARGIT HAALAND, M.B.,
STATE EPIDEMIOLOGIST, WESTERN NORWAY;
AND
MAGNUS HAALAND, M.D.,
PATHOLOGIST, MUNICIPAL HOSPITAL, BERGEN; SUPERINTEN DR. F. G. GADE'S PATHOLOGICAL INSTITUTE, BERG

ON the Western coast of Norway typhoid a paratyphoid B are still rather frequent. distribution is very unequal; in certain localiti disease is constantly recurring, whereas other areas are quite free A distribution of this kind s strongly for the presence of carriers.

Since 1919 a systematic search for carriers has undertaken at Dr. F. G. Gade's Pathological Ins in Bergen. Up to the present 42 carriers have found—18 typhoid and 24 paratyphoid B.

Of this total number one-half are old chronic c found in the endemic foci mentioned, 14 are new found by a careful control of convalescents whe excretion of bacilli has persisted more than a year, found by bacteriological examinations of gall-bl surgically removed for stones, and 5 by post-m examination. Of these 42, 3 were urinary carrie 39 intestinal carriers. In this latter group there 2 men and 37 women. The preponderance of the sex which is found everywhere is in our material even than usual. While in Germany about 75 per cent. hav found to be women and in Denmark 77 per cent., material the percentage at present is about 95 per cen

These carriers are scattered all along the coas to their occupation about half of their total numb wives of small farmers, having to do both the c for their family and the milking for sale. On i gation of the modes of infection for the seco cases, which are known to be infected from carriers, it is found that at least two-thirds of are due to milk or food infection. In the other the cases occur in the carriers' own family an be put down either to personal contact or t and food again. Thus in the cases studied mi food infections are dominant. The simplest w meet this danger, as far as the general pu concerned, would be to pasteurise all milk in districts, but so far it has been of little avail t for pasteurisation. As yet the State has beer too willing to give compensation for lost inco these carriers. The problem how to prevent in from them is therefore in Norway very di perhaps more difficult than in most other cou and one is forced to look around for some other to deal with them.

Removal of the Gall-bladder.

The main point of interest about these car that in a certain number of them the surgical re

* Read at the Pathological Section of the Royal So Medicine, Nov. 15th, 1927.

he gall-bladder has been carried out, as an attempt obtaining a final cure. It is well known that there close connexion between the carrier condition and presence of gall-stones. Without entering upon question of the relation between chronic typhoid lecystitis and stone-formation, it is enough to say t once a stone is formed which is too big to be reted through the bile passages, this will, for an finite period, prevent the gall-bladder from freeing lf from the typhoid infection. As long as the ie remains in the gall-bladder it both hinders hanically the complete evacuation of the infected and the fresh in-coming bile is reinfected by the ie. It is important to know whether stone-nation in the gall-bladder is the only typhoid focus hese carriers. There seems to be some confusion cytes have free access. Practically speaking, it is only where the bacilli are given facilities such as are afforded by a gall-bladder with stones or by the renal pelvis that the typhoid infection can be chronic.

This reasoning suggests that the carrier state as a rule is due to a purely local process in the gall-gladder. Where internal treatment does not help, and where every hope of spontaneous recovery must be given up there is only one rational treatment—namely, to remove the gall-bladder and drain the hepatic duct.

The removal of the gall-bladder is no small operation, but there is so much at stake that it may be fully justified. When the neighbours realise the constant danger of infection the carrier's existence out in the country is generally so miserable that he often prefers to take even a heavy risk, if there is any chance of

In this case the operation was cholecystostomy, because of the condition of the gall-bladder. In all other cases cholecystectomy.

this point, partly at any rate due to the fact the distinction has not always been made sharply gh between the more immediate after-effects of oid infection and the ultimate chronic carrier tion. In this chronic stage the gall-stone ubtedly plays by far the more important part. e is, of course, the possibility that in some cases rocess can go further. In one post-mortem case, ldition to cholecystitis and numerous stones, ave seen a paratyphoid cholangitis of the liver secondary cirrhosis and primary hepatic carna. But cases of this kind will give clinical toms, and they are late complications. It can be said that, as a rule, in the average healthy r, where there are no symptoms of a more faring process, the infection of the gall-bladder is an ed remnant of the infection. All surgical work gall-stones shows that, at any rate for a long this process is localised to the gall-bladder. The holds good for the typhoid gall-stones. Of erated cases in our series 13 show the process sed to the gall-bladder and to the gall-bladder . In this respect there is no reason to argue ently about a stone appearing after typhoid about stones of a different ætiology. After oid the organism is on the whole immunised st its own bacilli, and they have no chance of ving indefinitely where blood serum and leucogetting rid of the infection. Also, a stone in the gall-bladder is in itself serious enough, because of the possible complications, to justify the question of early removal being raised. And finally, from the point of view of the public health, the danger of spreading infection is often very great.

Indications for Removal.

Before the question of operation can be raised it must first be shown that the carrier state is a lasting one, that cannot be altered by internal treatment. Next the process must, as far as possible, be localised to the gall-bladder. Positive findings of typhoid bacilli in the fæces and in the duodenal contents, coupled with their absence from the urine, make it very probable that the process has its seat in the gall-bladder, this being the ordinary localisation, but this is not necessarily so. Complete certainty is only possible when there have been symptoms of gall-stones or where it is possible to demonstrate gall-stones by X rays. In some cases, but probably only rare ones, the process may be outside the gall-bladder, as has been the case in one of our 14 patients who were operated upon.

When these points are settled the surgeon will have to decide whether special contra-indications are present. In younger persons, where the operation may be supposed to be well tolerated and where there is no

reason to think of complications and no hope of spontaneous recovery, it seems rational to try operation, and we have systematically advised such carriers to have the gall-bladder removed.

Results of Operation.

Up to the present time 12 chronic carriers have been treated by removal of the gall-bladder; two further cases were operated upon for gall-stones and may be considered in the same series as paratyphoid organisms were found in pure culture from the gall-bladder. Of these 14 operations two have had an unfortunate course. One, a female inmate of a lunatic asylum, died six days after the operation. Post mortem it was found that the common bile-duct was ligatured and the bile was flowing into the peritoneum. The other showed at the operation adhesions round the gall-bladder; after the operation the flow of the bile through the external fistula persisted, but a second laparotomy failed to show any definite cause for this. A biliary fistula has in this case kept open; urinary infection with paratyphoid B has supervened and on the top of all this the patient has developed tuberculosis of the cervical glands.

In the other 12 cases the course after the operation has been quite normal. The flow of the bile through the fistula has ceased in a couple of weeks and the patient has left the hospital, in some cases as early as three weeks after operation, though as a rule the patient has been kept in the hospital for some time for the sake of the bacteriological control of fæces, urine, and duodenal contents.

In one of these 12 cases the action of the operation on the excretion of bacilli has been nil. In this case the operation showed that a wrong diagnosis was made as to localisation; there was no gall-bladder infection, the bile being quite sterile, and no stone. In this case the duodenal contents were not examined before operation, but they have been examined once later, and typhoid bacilli were found. The excretion of bacilli has in this case continued for seven years after operation, and to the present day it is not known where the infection is localised. The possibility of stones in the pancreatic duct has been considered, but no sure evidence of their presence has been found, either by X rays or by examination of the diastase reaction in the urine. We have here stumbled upon one of the exceptions from the rule and, at the present it seems as if we have no means of recognising such exceptions beforehand.

In the other 11 cases the operation has been quite successful, as also the excretion of bacilli by the fæces has stopped. Typhoid or paratyphoid bacilli can be found in the fæces some days after the operation; in one case paratyphoid bacilli were found for 20 days, but after this lapse of time it has not been possible in these 11 operated carriers to find the specific bacilli.

Bacteriological Control.

The bacteriological control of these operated cases has been made as complete as possible under the existing conditions. During the first period after the operation the fæces, urine, and in some of the later cases the duodenal contents have been controlled in the hospital as frequently as it has been found practicable. After discharge from hospital the examination of the fæces has continued, the patients sending to the laboratory samples of their fæces, taken after laxatives and under as much control as possible. The details of this examination will be found in the table. The length of time it has been possible to continue this control and the number of the examinations vary a good deal in the different cases; in one case the control has extended over 5¼ years after the operation with 22 negative tests. In later cases the demands for control have been lowered to one year and in a couple of cases there were 24 and 16 negative tests in the first 1–1¼ years after the operation. In other cases, again, the patients have been less willing to submit to the control, and it has only been possible to obtain more sporadic examinations; the numbers will be found in the table appended. The last operated ca are still under observation.

In addition to this bacteriological control there another mode of control possible in these cases. T population is relatively sparse on the Norwegian co and on the whole there is little difficulty in keep in contact with the operated cases and keeping effective epidemiological observation. Every case of typhoid in this part of the country is repor upon to the epidemiologist with all particulars ab their source of infection. Every new case of typh in the surroundings of these patients would at o attract attention, also every case in which sc connexion with an operated carrier might be e suspected. During the years that have passed si operation (the first patient having been operated as long as seven years ago) there has not bee single case of typhoid in the immediate surroundi of any of the operated carriers and no case in wh there even was a suspicion of any of them hav caused infection.

In consequence, so far as the observations go up November, 1927, both the bacteriological control a prolonged epidemiological observation offer evide to show that the operation of these 11 carriers effected a definite and lasting cure. Consequently operation may be justified in cases otherwise suita as a means in the systematic war against typh As long as there is no sure method of dissolving gall stones we shall have to fall back upon operation in cases where we wish to make an attempt at cu typhoid carriers, and we believe it is evident tha suitable cases a lasting cure may be effected.

CATARACT EXTRACTION WI PERIPHERAL IRIDECTOMY

NOTES OF TWO CASES.

BY J. N. TENNENT, M.B. GLASG., B.SC. LO D.O.M.S., F.R.F.P.S. GLASG.,

ASSISTANT SURGEON AND ASSISTANT PATHOLOGIST, OPHTHA INSTITUTION, GLASGOW ROYAL INFIRMARY.

EXTRACTION of cataract is an operation which l itself to a considerable number of modificati varying according to the nature of the eye and practice of the particular surgeon. At one time operator is quite content with an incision whic entirely corneal, while at another he is anxiou have a considerable conjunctival flap. One sur is satisfied with a mere division of the anterior ca of the lens, another endeavours to remove a pie the capsule, while a third aims at nothing less the removal of capsule and lens intact. The iris may be dealt with in three different ways. One me is to replace it in position, intact, after expressing lens; this operation is known as simple extrac Another method is to perform iridectomy, to re a portion of the iris, including the pupillary bo before removing the lens; this procedure is te combined extraction. The third method consis removing a small portion from the periphery o iris, usually after the lens is delivered; this is modern than the other two methods, and has ce advantages over both.

Prolapse of Iris.

Simple extraction, when successful, yields exce results. Unfortunately, however, it runs the ri a very serious complication—namely, pro of iris. This has been described as "la bête n of simple extraction. It may occur after the skilfully performed operation, and in that ty tranquil patient that is usually associated wi perfect result. At the first dressing, 24 or 48 h after the operation, the surgeon observes a po of the iris at the corneoscleral margin protru through the wound. This means that the woun opened, that aqueous has escaped, and that the

ish of aqueous has carried with it a portion of the is, which has remained between the lips of the ound. While it is true that a small incarceration iris in the wound—short of prolapse—may reduce self, and while tags of iris in a wound frequently rophy and cause no further trouble, yet prolapse iris delays healing of the wound, the aqueous con- nues to drain away, the anterior chamber remains en for a longer time, and so the risk of infection is creased. Infection may take place before the wound als, or it may occur later through the resulting catrix. If the piece of iris is not removed before lhesions occur, subsequent treatment is difficult and satisfactory. To operate on a prolapsed iris even on after its occurrence is difficult, because of the creased sensitiveness and irritability of the eye- ll, and a general anæsthetic is often necessary. ilure to deal effectively with prolapse of iris will nost certainly lead to further trouble. The cicatrix hich forms is permanently weak, and may yield fore the intra-ocular tension of the eyeball, forming ystoid cicatrix. Delayed infection is probable and ious. The patient complains of recurrent attacks redness and pain, a condition which at first yields treatment, but which readily relapses, the attacks coming more severe until intractable chronic clitis with its sequelæ is established. Sympathetic nthalmia is not unknown. It is surprising how quently microscopic examination of an eye in which clitis has followed cataract extraction reveals the sence of a small incarceration or prolapse of iris.

Many reasons have been given for the occurrence prolapse of iris after simple extraction. Most geons are agreed that anything which delays the ling together of the wound edges increases the of prolapse. A technique should be adopted ich will bring the lips of the wound together in fect apposition. The corneal puncture and counter- cture should be made about 1 mm. above the izontal meridian, and great care should be taken see that the plane of the incision remains parallel h the plane of the iris, otherwise the operator will bably find the wound gaping a little after the lens been expressed. When the lens is being extracted, iris must not be handled too roughly, or an atonic dition of the musculature will be induced pre- posing to prolapse. Atony of the iris occurs more quently when the cataract is hypermature. Another disposing cause of prolapse is avoided by expressing t of the cortical lens matter after the nucleus has n delivered. Prolapse of iris may be accidental. essive pressure from the patient's fingers or the dage, or careless manipulation of the bandage reopen the wound. Restless, anxious, nervous, tupid patients, or those with chronic cough, are e likely to have a rupture of the wound.

1897 Fuchs drew attention to the fact that apse of iris may occur in spite of the most perfect nique, and even in the most tranquil patients. nay occur when least expected, not infrequently ng the first night after operation, probably when patient is asleep. Fuchs suggested that it is ciated with a rapid agglutination of the wound. eous collects in the posterior part of the aqueous nber; for a time the balance between formation drainage of aqueous is upset, and the accumula- of aqueous continues until it reaches a point it causes a sudden opening of the wound. The ous behind the iris must escape, and as it does so rries with it a portion of the iris.

Operative Modifications to Avoid Prolapse.

hose who practise simple extraction of cataract routine must be prepared, on occasion, to deal prolapse of iris, and they will probably lose eyes as a result of chronic cyclitis. Because of many surgeons perform combined extraction. re expressing the lens, they deliberately excise rtion of the iris extending from the pupillary to the attached margin. This not only facilitates emoval of the lens, but also reduces the tendency rolapse. In some cases preliminary iridectomy may be performed some weeks before extraction of the lens.

Combined extraction, while certainly reducing the risk of prolapse of iris, has the disadvantages of loss of a functioning pupil. To avoid these the method of limiting iridectomy to the periphery of the iris has been introduced. After the lens is delivered, a small button-hole is made in the iris so that the sphincter iridis muscle is left intact. This method has three advantages over combined extraction. First, there is less disfigurement, probably none. When a portion of the iris extending from the attached margin to the pupillary edge is removed the coloboma is easily seen on close inspection. Most patients do not mind this disfigurement, but occasionally one does meet objections to what certain fastidious Americans call "the inverted keyhole." The peripheral hole in the iris, on the other hand, is covered by the upper lid, or is hidden behind the limbus corneæ, and is seen only when the patient looks up. In the second place, when the sphincter muscle is severed, the advantages of a contracting pupil are lost. When a strong light falls on the eye, the pupil normally contracts, but when this reflex is interfered with, a certain amount of dazzling must follow. Astigmatism resulting from the corneal wound will also be more troublesome when there is an extensive absence of iris underneath. These optical defects, however, are not of great importance, especially when correcting lenses are worn. The most important advantage of peripheral iridectomy over total iridectomy is that it entails less risk of prolapse of the lens capsule after extraction of the lens. Complete iridectomy is performed before the lens is expressed; then, after removal of the lens, the edges of the coloboma are replaced as far as possible with a spatula. The lens capsule at this stage is transparent, and one cannot always be sure that its remains are replaced in good position. In the other method, the iris is replaced intact with a spatula, and this is much more likely to prevent capsule protrusion. Then, when the iris and capsule are in good position, peripheral iridectomy is performed.

Historical Survey.

Peripheral iridectomy in cataract extraction was first performed by Charles Bell Taylor, of Nottingham. In 1871 he published a method of "extracting cataract by a peripheral section of the iris without injuring the pupil." Taylor removed a piece from the periphery of the iris *before* expressing the lens. The portion removed, while leaving the pupil intact, must have been of considerable length and oval rather than circular in shape, because the lens was expressed through the gap in the iris instead of through the pupil. In introducing this method, Taylor emphasised two points: (1) the risk of prolapse in simple extraction; (2) the advantage of a round pupil.

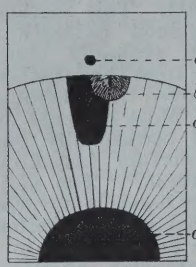
In 1890 H. B. Chandler, of Boston, described a somewhat similar method. He also performed peripheral iridectomy *before* dealing with the lens, but he delivered the lens "in the normal way," that is, through the pupil, and not through the gap in the iris.

The next important modification seems to have been introduced by Pflüger, of Berne. In 1897 he resuscitated the operation, and brought it before the notice of ophthalmic surgeons at an international meeting in Moscow. His modification consists in removing the peripheral piece of the iris *after* the lens is delivered. This alteration met with approval, and has remained the general practice. The operation is generally known as Hess's operation, but Hess did not introduce it. He did much, however, to render it more popular in Germany. In 1909 he reported his experience of 1000 cases. His special forceps for picking up a portion of the iris at the periphery is very widely used at the present time. Hess held that peripheral iridectomy is more successful than total iridectomy in preventing prolapse of iris.

From time to time operators have reported their results, and it appears that the operation is being

more frequently performed now than formerly. In 1923 Barkan, of San Francisco, published a careful analysis of 249 consecutive cases of extraction of cataract performed by Prof. Meller, of Vienna. In 180 of these cases Meller had performed peripheral iridectomy and, from his study of the results obtained, Barkan was convinced of the efficacy of this operation in preventing prolapse of iris. In 180 cases with peripheral iridectomy prolapse of iris had occurred twice, while in 46 cases of combined extraction prolapse had also occurred twice. Barkan adds: "A large capsule bite, persistent massage of the débris, peripheral iridectomy, and perhaps 10–20 per cent. discissions will yield as good an average result as any intracapsular operation, and much less actual loss."

FIG. 1.



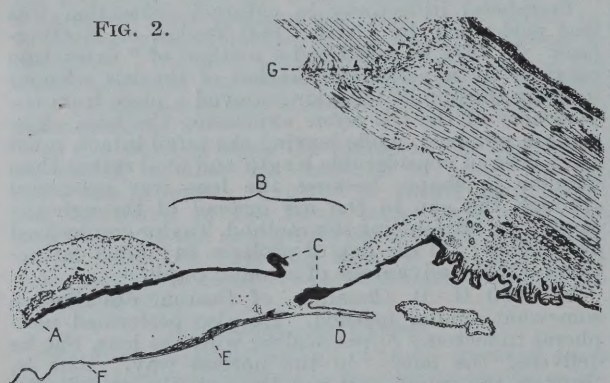
A. Small nodule of pigment under conjunctive. B. Proliferating pigment epithelium on posterior surface of cornea. C. Peripheral hole in iris. D. Pupil.

Peripheral Iridectomy.

Prolapse of iris after peripheral iridectomy is very rare. Sometimes, however, a little nodule of pigment appears under the conjunctiva after the wound has healed. The following case illustrates this less important complication.

Z. E., a male, aged 60 years, had a cataract extracted from the left eye on Jan. 9th, 1924. The eye healed well, and the patient was discharged from hospital a fortnight later. On August 28th he was readmitted to hospital for extraction of cataract from the right eye, and on this date the left eye was re-examined. The scar wound was found to be firm and flat, the anterior chamber was deep, and though some lens capsule remained, there was a central hole in it. V.A.L. $\bar{c} + 10{\cdot}5$ D.S. $= 6/6$, $\bar{c} + 14{\cdot}0$ D.S. $=$ J.I. On this date it was recorded that there was a small punctate pigment mass in the region of the wound. The cataract in the right eye was extracted on August 29th, with peripheral iridectomy. On March 30th, 1927, the patient returned to hospital for re-examination. He had no complaint and could see 6/6 and J.I. with each eye with correcting lenses. The corneal microscope and slit-lamp revealed an interesting condition in the left eye. Under the conjunctiva, on the outer surface of the wound, above one edge of the gap in the iris, there was a small black nodule of pigment—Fig. 1 (A). Underneath this, on the inner or posterior surface of the cornea, there was a dark flattened area of proliferating epithelium (B); this was not so densely black as the outer nodule, it was more rarefied and flattened, and showed dark radiating lines like the wing of a fly. One feels sure that if a microscopic section could have been prepared of the corneal wound, pigment would have also been found extending through the wound. There was no anterior synechia.

FIG. 2.



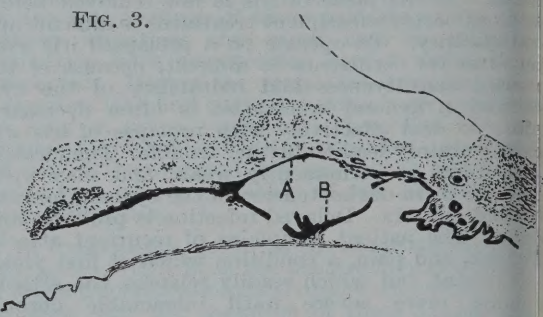
A. Sphincter iridis muscle. B. Gap in stroma of iris. C. Pigment epithelium of iris. D. Remains of anterior capsule of lens. E. Cortical lens matter. F. Posterior capsule of lens. G. Corneal cicatrix.

In this case cataract was extracted from both eyes by the same method. In each eye the vision was 6/6 and J.I. with correction, and the patient had no complaint. In one eye, however, there was pigm about the wound as described, while in the other there was no such complication. Neither eye shov any inflammatory reaction, yet the eye with pigment in the wound seems more likely to su from late infection.

Another case seems to throw some light on anatomical explanation of the presence of pigment.

H. Z., a female, aged 57 years, had a mature cataract the right eye and an incipient cataract in the left eye

FIG. 3.



A. Anterior layer of pigment epithelium of iris. B. Poste layer of pigment epithelium of iris.

April 28th, 1926. In childhood she had had inflamma in the right eye. In the right eye there was a superf scar of the cornea, the anterior chamber was of med depth, a little deeper than in the left eye, the pupil and were normal, and the lens was opaque, the cataract ext ing forwards to the anterior capsule. Light perceptio 6 metres was present, and light projection was good. cataract was extracted from the right eye on April 3 and peripheral iridectomy was performed. Prior to ex sion of the lens, a portion of the anterior capsule was rem with capsule forceps. Next day the anterior chamber deep, and very little remaining lens matter was to be s Subsequent healing of the eye was normal. The pa developed lobar pneumonia, and on May 12th was tr ferred to the Department of Internal Medicine. D took place on June 3rd, 1926.

The right eye was obtained for pathological examina A piece of the eyeball was removed on the nasal side, then vertical sections were prepared, 20 μ in thickness.

Fig. 2 is a drawing prepared from one of the sect passing through the hole in the iris. The sphincter i muscle is intact, and peripheral to it there is a gap in stroma of the iris (B). While a portion of the strom the iris has been removed, the corresponding portion o posterior pigment epithelium has been left behind This pigment layer has torn through at one point; it m easily tear at another point and then it would lie free i anterior chamber, and readily pass into the corneal wo this would give rise to the condition seen clinically in Ca Another interesting point is seen from the sections. F represents a section passing near to the hole in the it shows that the actual line of separation has been between stroma and pigment epithelium, but between two layers of the pigment epithelium. These two l of cells are only loosely attached to each other, they frequently separated in traumatic lesions of the eye, cysts in this situation are not uncommon.

In performing peripheral iridectomy the sur should endeavour to excise a piece of the w thickness of the iris. He must not press his for too deeply into the iris or through the hole in iris, or he will take vitreous, and probably find a wards a small synechia of the vitreous. No piece of the posterior pigment epithelium mus left behind, or it will probably become lodged in corneal wound, and may interfere with proper hea

There are certain cases in which it is bette perform total rather than peripheral iridect Generally, total iridectomy is preferable, where t is an increased risk of infection. If infection sh take place, the more complete mydriasis obta with atropine, when the sphincter iridis muscl severed, is an advantage. Chronic conjunctivit history suggesting infection of the lacrymal sa a highly pigmented iris rule out peripheral iridect The increase of pigment in the iris is suppose

associated with an increased toughness of the tissue, which makes the iris less susceptible to the of atropine. When for any reason it is considered visable to remove the lens in a case of intumescent aract, it is better to perform total iridectomy. e amount of cortical matter to be removed is reased, and it is more easily removed when there coloboma of the iris. Escape of vitreous generally es place after the lens is expressed, so there should as little manipulation as possible after delivery of lens; where there is increased risk of escape of reous, as in high myopia, preliminary complete ectomy is therefore more appropriate than peri-ral iridectomy, which is usually done after delivery he lens.

part from these exceptional cases, cataract raction with peripheral iridectomy will largely lace simple extraction and combined extraction, e it combines the advantages of both.

he two cases recorded above are from the First Clinic, General Hospital, Vienna, and I desire to nk Prof. Meller for his kindness in allowing me to e use of his material. I also thank Dr. A. Fuchs his suggestions and encouragement.

TREATMENT OF
RGICAL TUBERCULOSIS IN CHILDREN
WITH SPECIAL REFERENCE TO TUBERCULOUS DISEASE OF THE SPINE.*

J. G. JOHNSTONE, O.B.E., M.B., CH.B. ABERD.,
DICAL SUPERINTENDENT, HEATHERWOOD HOSPITAL, ASCOT.

NTIL a specific remedy for surgical tuberculosis scovered the modern conceptions of general and treatment will prevail. The modern method of eral treatment aims at increasing the patient's ral resistance to infection and demands a special of hospital, specially equipped, staffed by experts, specially designed in suitable surroundings. re selecting the site meteorological records should aken of the area over a considerable period. perature, humidity, sunshine, rainfall, nature of il, elevation, and prevailing winds should be tained. The temperature should be variable n limits. The humidity should be low, seldom ng above an average of 60 per cent. for the year. hours of sunshine should be as high as possible e district. A site with a high rainfall and a loose subsoil is better than a site with a moderate all and a heavy clay subsoil in a sheltered ion. These factors have a decided effect upon ocal humidity. The site should be the highest nable in the neighbourhood. The institution d be erected on a southerly exposure. Humidity tremely important, as it influences the number urs of exposure to the sun and air that can be itted in the year. The more a patient can be sed in the open air to the radiant energy of the the better will his powers of resistance become. h humidity makes it impossible to expose patients for any length of time, as the heat loss from the body is too great, whilst evaporation of water from the skin is small. The metabolism of the patient in the presence of a high humidity is not increased to the same extent as when the temperature is high and the humidity is low, and there is not the same flushing of the respiratory mucous membrane. The degree of humidity is decidedly influenced by the nature of the subsoil and the prevailing winds. At Ascot we find that the humidity rises with a west wind and falls with an easterly wind. A high humidity is especially trying to patients under 7 years of age and to weak, debilitated patients who are apt to develop nephritis after persistent exposure. A sheltered site should not be chosen as the movement of air over the exposed body has an enormous effect on its radiation of heat and evaporation of moisture. This is shown in the calm suffocating days of midsummer, when the patient demands to be taken inside.

Principles of Heliotherapy.

Covered-glass verandahs should on no account be erected as they become hot-houses in the summer and reduce the air movement in winter.

Heliotherapy practised under ideal climatic conditions has a most beneficial effect upon the patient's metabolic and mental processes. It must not be forgotten that many patients soon become acclimatised to their environment; they develop a tolerance and cease to react. On the other hand, some cases may be tired out by over-stimulation, to the detriment of their general condition. Patients who rapidly develop a tolerance are those that respond and pigment readily. Their metabolic processes cease to increase, and it is of value to have a second institution under different climatic conditions to which cases of this kind may be transferred. The great value of heliotherapy is largely due to the ever-varying conditions which call for an effort of the organism and help to maintain the individual response. The patient is kept in a condition of unrest, and so long as the strain is not too great, so long will benefit result. The symptoms of fatigue are lassitude, sleeplessness, loss in weight combined with a stationary or retrogressive condition of the local lesion. Gross overdose is recognised by excessive erythema, malaise, pyrexia, and increase in pulse-rate. In children under 7 overdosage has to be carefully avoided.

Phototherapy.

The benefit of phototherapy in surgical tuberculosis is now well recognised. Its results are not so brilliant as those obtained from heliotherapy under ideal conditions, but it is a decided acquisition where heliotherapy cannot be practised for long periods of the year. Heatherwood Hospital, Ascot, is an official air station of the Air Ministry, so records of the weather conditions are kept daily. I have prepared a chart from October to March for the past five years which shows that it would not be desirable to expose children under such conditions.

Meteorological Records at Heatherwood Hospital: October to March, 1922 to 1927.

I maintain that a properly constructed and equipped artificial light department is essential in a hospital for surgical tuberculosis. Although many of the claims made for phototherapy cannot be substantiated either by physiological or biochemical evidence, it has proved its value and is an important form of treatment in countries where the climatic conditions during the

*ased upon a paper read at the International Congress of stitute of Public Health, Ghent, 1927.

winter months do not permit of heliotherapy or aerotherapy.

It should in no way supplant any orthopædic measures, but should be used in conjunction with and secondary to immobilisation in all cases. I consider that we are in grave danger of losing perspective in the present wave of enthusiasm for light treatment. Orthopædic treatment should undoubtedly take precedence in all cases. It is wrong to take from a patient suffering with tuberculous arthritis his mechanical apparatus for immobilising the joint, in order to expose a large area of skin surface. Immobilisation should be maintained at all times. The retentive apparatus should be designed so as to carry this into effect, whilst at the same time permitting the exposure of as much skin surface as possible. Failure to appreciate this will bring both heliotherapy and phototherapy into disrepute, and the good results which can undoubtedly be obtained in every case when the two methods are properly coördinated will not be forthcoming. Without adequate immobilisation, bone destruction will progress, deformities will arise, and abscess formation will occur.

In erecting an artificial light department, the natural Alpine sun conditions should be imitated as far as possible. This demands attention to space, ventilation, and a variety of lamps of different ampèrage and type. It must be recollected that no ray or group of rays is specific for tuberculosis. Their action upon the human body is enhanced by attention to the other factors. The general light bath in the absence of factors such as temperature, moving air, and the change of stimuli may do harm. The chief aim of phototherapy is to increase the patient's metabolism and raise the hæmobactericidal power of the blood, thereby raising the general resistance of the patient to the tuberculous infection. It has been definitely proved that artificial light per se does not raise the metabolism; it induces the production of increased tissue change by reduction and oxidation of the cellular constituents, but these are apt to stagnate unless there is movement of fresh cool air over the skin surface and into the lungs.

The Equipment of the Light Room.

We are satisfied with the window gravity system in combination with an extractor fan by which 26 changes of air can be obtained in an hour. The fan and ventilators are capable of adjustment to meet the varying external atmospheric conditions. Provision should be made to heat the department so that naked patients do not come into a cold room. The roof of the department should be arched, and have large ventilating grids at the summit. The carbon-arc lamp has proved the best source of radiation for surgical tuberculosis; it should be remembered that it burns at a temperature of 2000° to 3000° F., so that an adequate ventilating system ensures good cooling of the patient's body. It is bad practice to allow patients under treatment to perspire profusely; it is most debilitating and fatiguing, and the object of the treatment is to stimulate. Good cooling of the body with evaporation assists metabolism. No draughts should be created, as they affect the burning of the arc. We attempt to maintain the temperature of the light room between 65° and 75° F. Variation to prevent tolerance is obtained by using different ampèrage carbon arcs with differently cored carbons, alternating with the mercury-vapour type. In this way the response of the patient to the stimuli is maintained and no lack of mild erythema is seen after treatment.

According to Grotthius's law, only rays which are absorbed have any chemical action. As the penetrative power of any ray of light depends upon its angle of incidence, it is important that the surface of the patient's body should be at right angles to the direction of the rays. The rays of the carbon-arc lamp with direct current are emitted in a cone of light in a downward direction. The patient should be at a lower level than the source of light. All patients with active disease are treated in the prone position and strictly immobilised by a number of straps on a rotatory frame specially designed for the purpo. Ambulant patients sit with specially designed cellulo splints. The body is divided into four surfaces- anterior, posterior, and right and left lateral. T initial length of treatment is 30 minutes, divid equally for these four areas. The maximum length f treatment is two hours for the carbon-arc lam. Hourly readings are also taken of the room tempe- ture. The problem of unit of dosage has not been t satisfactorily solved on account of the numer(s physical difficulties, but I am convinced that un this is accomplished the treatment is largely empiric. Pigmentation is not looked upon as curative in its but merely as an indication that a patient has develop a response to the stimuli and has more readily adapt himself to the call made upon his organism. Te pigmented patient is able to stand a heavier dose f radiant energy, and this is beneficial to his conditi. It is a well-known physical fact that a body with a darkened surface can absorb and give out more radi t energy than one with a light surface. The same lv holds good for human beings. A pigmented pati t can keep his tissues in a more equable condition dur g treatment. I do not intend to enter into the t- chemical effect of light on the human body, as e matter is by no means settled. There are may fascinating theories, but they are too conflicting a contentious for the scope of this paper. Diet y is an important factor in the general treatme. Attention has recently been focused upon the impo- ance of giving animal fat in liberal amounts.

Local Treatment.

The local treatment of surgical tuberculosis may e briefly summed up in three main principles: (1) Te site of the active focus must be immobilist. (2) Pressure or weight-bearing must be removl. (3) Any existing deformity must be improved a any other occurring in the joint affected or any ot r joints must be prevented. These principles must e strictly carried out until the disease has beco e arrested. In the early acute stage, rigid immobilisat n combined with all relief from pressure is most essen l in helping to limit the amount of destruction in e joint surfaces and excessive thickening of the synov l membrane.

Later, when the progress of the bone disease s stationary, the probable end-result has to be consider t. There are three main types of end-result in cases f tuberculous arthritis: (1) Practically normal mo- ment. (2) Considerable limitation of movement, e either to extensive bone destruction or abundance f fibrous tissue with greater or lesser amount of jo t derangement. (3) Sound bony ankylosis. There s a stage in all cases at which the methods of treatm t must be modified according to the group into wh the patient will ultimately fall. It is a very interest g and often a difficult decision to make. I am firmly convinced that the worst end-results are those f Group 2 and that most of the relapses occur he- I am of the opinion that in those cases where the ra e of movement in the joint is likely to be less th n 50 per cent. of the normal, one should aim at a sou d ankylosis. In Group 1, after the acute stage s passed, the rigid immobilisation is replaced by n apparatus that allows of a certain amount of moveme t. Prolonged rigid immobilisation, by means of plas r- of-Paris, Thomas's spinal frame, or a Thom s abduction frame, tends to produce ankylosis. Ca s, on the other hand, which are likely to fall i o Groups 2 and 3 should be retained throughout n a rigid immobilising apparatus. The type of appara s employed has a definite influence on the end-res t. It should be a definite aim of the surgeon to forc e and influence the end-result of all cases of disease f a major joint. Cases that could be made to fall i o Group 1 often end in Group 2 because they h e been subjected to over-prolonged rigid immobil r- tion. Similarly, cases that could be made to fall i o Group 3 end in Group 2 because they have not b n subjected to sufficiently prolonged immobilisation.

Heliotherapy and artificial light tend to limit or uce the formation of fibrous tissue. A certain gree of splintage should be maintained in all cases r long periods after the patient has left hospital. cases of secondary infection with fistula formation connexion with disease of the minor joints, I have considerable success with the application of raw ooked pork fat to the sinus. A certain degree of cess has attended the use of quartz rod applicators ached to a mercury-vapour Kromayer lamp to ilar sinuses.

Hyperextension for Kyphosis.

n the treatment of tuberculous disease of the spine hildren there is considerable diversity of opinion the advisability of attempting to correct the hotic deformity. There are three groups: (1) Those maintain that the existing deformity should be wed to remain and who devote all their attention ards the arrest of the disease by fusion. (2) Those advocate masking the deformity by the creation ompensatory curves above and below the kyphosis. Those who direct their attention to arresting the ase and the direct reduction of the existing hosis. I maintain that it is possible and desirable dopt the third line of treatment in all children re the destruction is not too extensive and the osity not too well marked. It is proved beyond ment that pressure upon a tuberculous focus is imental to the resolution of the disease and urable to the continuance of the pathological ess. It follows, therefore, that it is an essential ll treatment to remove this pressure. It is not cient merely to immobilise the patient in the e position; it is necessary also to treat him by erextension of the spine. Those cases where the n has taken place between two or more vertebræ a remaining well-marked kyphosis have the re of gravity alignment of the spine in the erect ure displaced forwards, with the result that the rmity tends to increase until the child reaches t life, unless a spinal support is worn for many s. The same applies to those cases which rely on pensatory curves. In many cases where the bodies e vertebræ have not been entirely destroyed, as n by a lateral skiagram of the spine, and where still exists a nucleus of living calcified bone it is better to hyperextend the spine at the of the disease to allow the bone cells room to iply and calcify. If the intervertebral disc has destroyed, fusion of the vertebræ will still take . By gradually increasing the degree of hyperxion greater freedom is given for growth of the sed vertebræ. There is no constriction or limitaof blood-supply to restrict the development of osteoblasts and fibroblasts that are laid down.

e technique necessary to obtain this is very simple. e beginning of treatment a soft wedge pillow is d underneath the patient, with the base of the e under the highest point of the kyphosis. This placed after a few weeks, when the patient's skin rithstand the pressure, by a padded wooden block the apex of the gibbosity. This in turn is aced in resistant cases by blocks of increasing s, so that the hyperextension of the spine is ily accomplished. Children are strapped to their l boxes in this position. In low lumbar cases highs are also immobilised to prevent flexion spine in this area. After some 15 to 24 months s position, the children are turned to the ventral on with the spine retained in hyperextension eans of a bed-rest for the upper part of the trunk, ibbosity being opposite the lowest point of the h of the mattress. During this period a certain m of movement is allowed, which must be in irection of further extending the spine. This on is sought for the development of the atrophied muscles by means of use and exposure to the nts. It is found extremely difficult, indeed t impossible, to reduce a kyphosis occurring as lt of disease in the upper six dorsal vertebræ, should be attempted in other areas. I have ured the rate of growth that has taken place in the seat of disease compared with the normal vertebræ in the following cases. Many others could be cited.

Case 1. In 5 years ..	Normal	vertebræ have grown.	45 % = 9 %	p.a.
	Diseased		100 % = 20 %	,,
,, 2. In 4 years ..	Normal		45 % = 11 %	,,
	Diseased		75 % = 19 %	,,
,, 3. In 4 years ..	Normal		45 % = 11 %	,,
	Diseased		90 % = 22·5 %	,,
,, 4. In 3 years ..	Normal		20 % = 6·7 %	,,
	Diseased		45 % = 15 %	,,

It will be seen, therefore, that the rate of growth in the diseased vertebræ is approximately twice that of the normal vertebræ.

A lateral view of the spine demonstrates the reconstruction of the bone into a quadrilateral-shaped mass instead of the wedge-shaped mass that is usually seen after other methods of treatment. The position of the gravity-centre of the spine is replaced to its proper position in the erect posture. When all activity of disease has ceased, as shown clinically and radiologically, the child is allowed to walk about in a celluloid spinal support. The cast for the celluloid cuirass is taken with the spine in hyperextension. The position of hyperextension is maintained by means of such an apparatus for a varying period up to two and three years. This demands expert aftercare of the patient after he leaves the hospital. This should be carried out by the same surgeon who has supervised the in-patient treatment.

Clinical and Laboratory Notes.

ANOTHER CASE OF FOREIGN BODY INADVERTENTLY SWALLOWED.

BY W. J. E. LUPTON, O.B.E., M.B. OXF.

Dr. S. F. Allison's report in THE LANCET of Nov. 5th of the case of Foreign Body Inadvertently Swallowed recalls the following case which occurred recently in Oxford. A school-boy of 11 to 12 years of age introduced into his stomach a length of wire with sharp, penetrating ends. In Dr. Allison's patient the foreign body passed along the whole length of the alimentary canal without catching or penetrating, but in this case the wire pierced the stomach wall and protruded into the peritoneal cavity, causing death.

On Oct. 4th, 1927 (Tuesday), I was called to see a boy who had "pains in his stomach"; I saw him between 11.30 A.M. and noon. He was an orphan, and had lived since August last with an aunt and uncle; the aunt stated that he had first complained of pain on the previous Friday; the pain was then in about the middle line of the body high up in the abdomen; he had, however, attended school that day as usual. On the Saturday he still complained of pain, but located it more over to the right side; he was up and about that day and took his food well. On the Sunday, as he was no better, the aunt dosed him with salts, and the bowels acted freely; he now had pain down the right side of the abdomen, which was sharp and stabbing at times; on the Monday the pain down the right side was bad, and aggravated by movement. So far as the aunt was aware the boy had had no food outside their ordinary diet; he had not felt sick or vomited, and his appetite had been good. There was no suggestion made then or at any time, either by the boy himself or by any relative, that he had swallowed a foreign body.

On examination the temperature was 99·7° F., pulse 96, respirations 24; the tongue was thickly furred; the upper right rectus muscle was rigid, definitely on guard; there was tenderness on pressure and hyperæsthesia to pin-prick on the right side, from the costal margin downwards towards the groin, and more evident near the costal margin. There was, however, no definite tenderness, even on deep pressure, over McBurney's point or the cæcal area, while the abdomen appeared to move normally on respiration. The spleen was not palpable, and there were no physical signs of any liver or gall-bladder involvement; rotation of the hip-joint and flexion of the thigh on the abdomen elicited wincing, and examination per rectum gave some tenderness on the right side. The indication was an inflamed appendix of an aberrant—e.g., retrocæcal—type.

When seen again with Dr. H. A. Robertson between 8.30 and 9 P.M. the boy's temperature was 100·4° F., and pulse-rate 104, and he looked more definitely toxic. He was removed to the Radcliffe Infirmary and County Hospital, Oxford, and was operated on there the same night (Tuesday), within an hour or two of admission, by Mr. H. A. B. Whitelocke. The appendix was found normally placed, elongated, but not obviously inflamed; it was removed, and the incision was closed in the usual way. A right upper paramedian incision revealed a piece of wire, some 2 inches in length, protruding from the pyloric end of the stomach into a round, fibrinous, ulcerous mass of omental tissue, some 2 inches in diameter. The wire was drawn out, the area cleaned of a small quantity of pus, and a drainage-tube inserted. The boy stood the operation well and passed a good night. Next morning he was mentally alert, and stated that he had no remembrance of ever having swallowed any wire. He was, however, somewhat cyanosed and dyspnœic; this dyspnœa increased towards evening, his condition became bad, and he expired rather suddenly almost exactly 24 hours after the operation.

At the autopsy made by Dr. A. Gibson, physician and pathologist to the hospital, a small ulcer was found in the stomach wall just proximal to the pylorus; on the other side of the stomach wall w a hæmorrhagic-looking fibrinous mass, on the wh soft to the touch, situated on and in folds of t omentum. Death was apparently due to gene peritonitis. From the appearance of the fibrin mass, which was recent-looking and unorganis Dr. Gibson suggested that the wire had been in s for some eight or ten days before the operati Examination of the body at the post-mortem revea no avenue by which the wire might have found way into the stomach other than the mouth. apparently worked its way very gradually throu the stomach wall. The wire was about the ga of thick nasal snare wire, and was not eroded.

The relatives are unable to account for the wi they have no wireless set in their house, nor a other apparatus involving the use of wire.

My grateful acknowledgments are due to Gibson and Mr. Whitelocke, of the Radcliffe Infirm and County Hospital, Oxford, for their generous h with these notes and permission to record this c

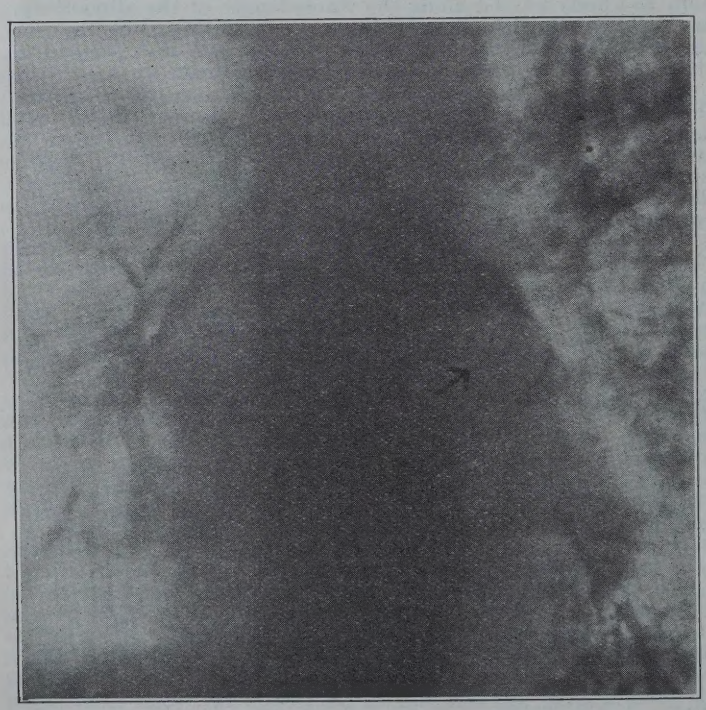
A CASE OF FIBROMA OF THE BRONCHUS.

BY L. S. T. BURRELL, M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL FREE HOSPITAL AND TO THE BROMPTON HOSPITAL FOR CONSUMPTION;
AND
R. R. TRAIL, M.D. ABERD.,
MEDICAL SUPERINTENDENT, KING EDWARD VII. SANATORIUM, MIDHURST.

A FIBROMA of the bronchus leading to severe hæmoptysis is very uncommon, and we think that the description of a case may be of interest.

The patient, a lady of 23, had hæmoptysis in May, 1925 and again in June and October. Apart from these attack she was perfectly well. She was sent to Midhurst Sanatorium, and there she had another large hæmoptysis in May, 1926, and was in bed for 18 weeks with practically continuous hæmoptysis.

FIG. 1.



Radiogram showing right and left bronchi and the position of the tumour.

There was very little sputum and tubercle bacilli w never found. Breath sounds were a little weak in the f middle zone, and movement was quite definitely diminis

FIG. 2.

over the left lower lobe, but there was no ness and no adventitious sounds were h X ray showed nothing abnormal in the chest

It was thought that she might be a ca bronchiectasis of the type described as "f sèche hémoptoïque," and some lipiodol injected through the cricothyroid memb The X ray examination by Dr. Stanley Me showed very clearly that a large bronchus blocked (Fig. 1).

Mr. V. E. Negus then examined her w bronchoscope, and reported that there w smooth, solid new formation in the top o left lower lobe bronchus, filling up the lu It was attached to the wall of the bronchu bled slightly when touched. On Dec. 9th, he removed the growth through a broncho by nibbling it away in about six pieces w long, cupped forceps. The growth proved t fibroma, and a section is shown in Fig. 2. S quent examination with the bronchoscope sh the left lower lobe to be free from remains fibroma. The after-progress was uneventfu the recovery apparently complete.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

ATE RESULTS OF OPERATION FOR CARCINOMA OF THE BREAST.

AT a meeting of this Society, held on Nov. 28th, r. HERBERT CARSON, the President, occupying the air, a report was presented by the committee pointed in July, 1923, to investigate the after-results operations for cancer of the breast. The members of e committee were Sir James Berry, Mr. Warren Low, r. Percy Sargent, Mr. Carson, and Mr. T. P. Legg. ıe scope of their inquiry was limited to the tracing d investigation of patients for whom the preliminary eration was performed not less than ten years eviously. Inquiry forms were sent out to surgeons ached to various hospitals in the British Isles, d from the replies received 265 cases were analysed d tabulated by Mr. W. E. Tanner.

Summary of the Report.

Of the 265 patients: (1) 195 (73·6 per cent.) were ve and well, with no signs of recurrence, at intervals m 10 to 34 years after the primary operation. Ten patients (3·8 per cent.) were alive and well intervals of 10 to 26 years after the primary eration, but had undergone an operation for cinoma of the other breast. In one of these more n 10 years had elapsed since the second operation; the other nine the interval was less than 10 years. Four patients (1·5 per cent.) had operations for cinoma in other parts of the body—the rectum, vic colon, and cervix uteri. (4) Ten patients (3 per cent.) were alive and well at periods from to 21 years after the primary operation, but had l one or more operations for recurrence. (5) Fifteen ients (5·7 per cent.) were alive from 10 to 24 years r the primary operation, but had evidences of urrence. (6) Twenty-one patients (7·9 per cent.) l with recurrence more than 10 years after the nary operation, at intervals of 10 to 25 years. Ten patients (3·8 per cent.) died more than 10 years r the primary operation at intervals of 10–32 years, hout signs of carcinoma. These cases were carefully stinised to exclude carcinoma as the cause of death.

Of the 265 patients who were alive more than years after the primary operation, recurrences eared in 46 (17·4 per cent.). These 46 patients into two groups:—

(a) Ten were alive, with no signs of cancer, but had an operation for recurrence. It is interesting notice that these recurrences were all local, with exception of one, in which the recurrence was he skin over the lumbar spine. Three of these rrences occurred within one year, three between and two years, two between two and three years, between five and six years, and one 14 years r the primary operation.

It would appear that operations for local recurrences be very satisfactory, and may be followed by periods of freedom from the disease, if not by al cure. They are, therefore, well worth undering whenever it is possible to remove the recurrence ly and widely.

(b) Fifteen were alive with signs of recurrence of cer, and 21 died of recurrence of cancer more than years after the primary operation. The site of rrence was as follows:—

Site of Recurrence.

l only	16	Supraclavicular	6
l and mediastinal ..	1	Mediastinal and supra-clavicular ..	1
l, mediastinal, and abominal	1	In soft tissues of thigh ..	1
l and spinal	1	Site unknown	1
astinal	3		—
ominal..	3		36
ary	2		

In nine of these patients the recurrence appeared lly within 10 years of the primary operation, and in seven between 10 and 25 years. In the six patients with supraclavicular recurrence, this occurred in two patients within one year; in three the recurrence followed between 9 and 10 years, and in one patient 24 years after the primary operation. In another patient involvement of the supraclavicular glands and mediastinum occurred 10 years after the primary operation.

The question of removal of supraclavicular glands as a part of the primary operation is still undecided. Of 11 patients in whom these glands were removed 10 remained well from 11 to 14 years; the remaining one was alive with metastases in the liver and peritoneum 13 years after the primary operation. It should be noted, however, that in none of the 11 were cancerous glands present at the time of the operation above the clavicle. The case is entirely different when the supraclavicular glands are obviously infected. This infection may arise from a direct spread from the axillary glands, or it may be secondary to mediastinal infection. In the latter case operative removal would be unavailing; in the former it is doubtful if operation ever removes the whole of the disease, which may have spread into the mediastinum from these supraclavicular glands.

In one patient the local and mediastinal recurrence took place 10 years after the operation; in the patient with local, mediastinal, and abdominal recurrence the interval was 14 years; in the patient with local and spinal recurrence 12 years. In the patients with mediastinal recurrence only, in two the disease appeared in 10 years and in the other in 18 years after the operation. The abdominal recurrences took place 1, 8, and 12 years after the operation. The axillary recurrences followed 3 and 13 years, and a recurrence in the soft tissues of the thigh 11 years after the primary operation.

Summarising groups (*a*) and (*b*), in 25 patients the recurrence was local—i.e., in the area of the primary operation. In 17 of these patients the recurrence appeared within 10 years; in 6 patients it occurred between 10 and 15 years; and in 2 patients between 20 and 25 years. The details are more clearly set out in the following table:—

Time of Recurrence.

	Patients.		Patients.
0–1 year ..	.. 7	10–11 years	.. 2
1–2 years ..	.. 3	11–12 ,, ..	.. 5
2–3 ,, ..	.. 3	12–13 ,, ..	.. 1
3–4 ,, ..	.. 1	13–14 ,, ..	.. 3
4–5 ,, ..	.. 1	17–18 ,, ..	.. 1
5–6 ,, ..	.. 2	21–22 ,, ..	.. 1
6–7 ,, ..	.. 1	23–24 ,, ..	.. 1
7–8 ,, ..	.. 2	24–25 ,, ..	.. 1
8–9 ,, ..	.. 1		—
9–10 ,, ..	.. 8		46
Less than 10 years	2		

Looking at this table, a striking feature is the small number—four patients (8·6 per cent.)—with recurrence after 14 years. The figures perhaps are too small to draw any wide generalisation from them, especially as in some of the years nearer the date of the primary operation only one recurrence in any year is shown in the table.

The critical times after the operation would appear to be the first three years; there were 13 patients (28 per cent.) in whom recurrences took place in these years; and between 9 and 10 years, when there were 10 patients (22 per cent.) in whom the recurrence occurred; and again between 10 and 14 years, when recurrence happened in 11 patients (24 per cent.).

The committee had hoped to draw some definite inferences with regard to prognosis from the situation of the growth in the breast. The figures and tables do not enable them to make any dogmatic statement. They think, however, the order of prognosis in a descending scale is as follows: (1) lower half of the breast; (2) outer half of the breast; (3) upper half of the breast; (4) central; and (5) inner half of the breast. Excluding central tumours, the lower and outer half of the breast is the most favourable, and the two inner quadrants the least favourable.

"We should like to reiterate the statement," the committee conclude, "that the prognosis in young patients is not so hopeless as is generally believed."

Discussion.

After Mr. T. P. LEGG had presented the report, the PRESIDENT said that the Committee regretted they had been unable to find one common causative factor in recurrences; they had been much cheered, however, by the success attending the treatment of local recurrences.

Mr. W. E. MILES, speaking from 28 years' experience of cancer of the breast, said that when he was appointed assistant surgeon at the Cancer Hospital the operation he performed was considered a bold one—viz., removal of the breast and subjacent pectoral fascia, with a thorough clearance of the axilla. In several cases small recurrences were noted in the neighbourhood of the scar, showing that removal of the skin had been inadequate. Also there was an extension along the upper border of the latissimus dorsi fairly constantly. When the more extended Halsted operation was done it was found to prevent much recurrence in the extra-thoracic lymphatic areas. Patients differed widely in the degree to which their tissues were invaded by cancer cells, and resistance by the patient played a great part in the ultimate success. Mr. Miles did not consider that the end-results were better to-day, after the routine adoption of larger operations, than in earlier days after the more restricted ones. Discussing technique, he said that occasionally metastases occurred in the supraclavicular glands, and he concluded there was a portion of tissue lying between the apex of the axilla and the supraclavicular fossa which could not be dealt with by dissection of the supraclavicular fossa alone. He had therefore conceived the idea of removing the clavicle, and had found that this gave an excellent exposure of the whole area. There was much luck in operations for cancer of the breast.

At the Cancer Hospital, Mr. Miles declared, he had never seen a case of cancer of the breast which had been cured by X rays. But it seemed reasonable that after excision of the growth, and after an interval long enough to prevent the X rays causing pain in the wound, the site of operation should be exposed to the rays so as to destroy isolated cancer cells which had not been removed. Therefore he had made a practice of sending his post-operation cases to the electro-therapeutic department, but he had been amazed to find that recurrence after use of X rays in this way was earlier and more rapid than in cases treated by surgery alone. Again, he had never seen a case of cancer of the breast which he could say had been cured by radium. In some cases a shrinkage seemed to have followed the use of radium, but afterwards the distant metastases seemed to flourish even more than they would otherwise have done. He did not think sufficient time had yet elapsed to form an opinion about the value of Mr. Sampson Handley's use of diathermy for removal of the breast. But the idea did not appeal to him, because he did not see how a momentary application of diathermy would have any effect on the deeper-seated extensions of the disease. As only 15 per cent. of the cases of mammary cancer treated at the Cancer Hospital had been alive after ten years there was not yet much to be proud of, and at present the relief of about one patient in six was all that could be hoped for.

Mr. W. SAMPSON HANDLEY considered that the Committee had performed an important public service in compiling, and especially in hall-marking, a substantial number of cases at various periods after operations for cancer of the breast, because there was deeply rooted in public and professional thought an idea that cancer was incurable, an unreasoning pessimism which was largely responsible for the difficulties of surgeons. The attitude of the public when a lump appeared in the breast, too often seemed to be: If it is not cancer there is no hurry; if it is, there is no hope. A large number of private cases of his own showed that the average period of delay before seeking advice after a swelling was noticed w six months. The report was a necessary antidote the too prevalent pessimism about cancer, and it w to be hoped that one result was that patients wou seek advice much earlier. If operation was carri out before axillary glands were affected four out every five patients would remain well for a number years. He thought that it was possible to tell recurrence in the opposite breast from a new develo ment of cancer in it. If the lump in the opposi breast was a recurrence hard glands were alwa present in the opposite axilla, and were evident bef the lump appeared; whereas if the lump in t opposite breast was a new cancer, it would be detect before any axillary glands were palpable. He w glad the report paid attention to persistence of tre ment in cases of local recurrence; too many were a to give up when recurrence took place after the fi operation. And the report disposed of the contenti that permanent cure was impossible if a prelimina "incomplete" operation was performed. The d crepancies existing in the descriptions of the differe people whose work entered into the report showed t need, he thought, for the formation of a standa histological collection of new growths; it al showed the necessity of maintaining a supply competent histologists and the provision of prop dignified appointments—to attract able men associated with histological study. He did not dou the prophylactic value of radium in the right pla at the time of the operation. For seven years he h used it along the internal mammary chain, and at t lower and inner angle of the posterior triang. Since he did that his private results had improv 90 per cent.; indeed, it was almost unknown a recurrence to have taken place in the regions th protected by radium. Unlike Mr. Miles, he thoug the results of operation for mammary cancer wer matter of education of the public, not of lu. Diathermy possessed great advantages, and thou it could not be pretended that it could deal with de deposits, prevented the implantation of cancer cells the wound surface. It also minimised shock, a on the whole, he felt it was a definite improvem on the knife. Healing was just as good.

Mr. A. J. WALTON showed tables of results in s own clinic. He regarded them as far from satisfact and suggested that those who spoke hopefully of th cases would be more pessimistic if they had a go follow-up agency at work. He did not like to ap X rays as a routine treatment, but in attack secondaries their effect had been marvellous, thou these results might prove to be only fleeting.

Mr. JOCELYN SWAN gave figures from his practi at the Cancer Hospital. Of 478 patients with can of the breast 64 were alive and well ten years af operation. In his earlier work he had removed supraclavicular glands in many cases; he did n remove the whole clavicle, but divided it, stretched two segments apart, and took away the tissue betw the axilla and the supraclavicular area. Not one the patients thus treated had lived ten years, a he concluded that if a patient had palpable sup clavicular glands, no radical operation was practica Another conclusion he had formed was that in m cases in which the supraclavicular glands w involved the line of spread was not direct from axilla to these glands, but via the internal mamm group, passing upwards into the neck. He conside that when cancer appeared also in the opposite bre it was nearly always a separate disease, not a rec rence in another site; he had seen different mic scopical structures in the two breasts in such a ca He agreed with what Mr. Miles said about the res of using X rays and radium.

Dr. STANLEY WYARD expressed the hope that t discussion on the report would not see the end of it should be published for the information and guida of a much wider circle.

Mr. DUNCAN FITZWILLIAMS said that when a patient came for operation for cancer of the bre the surgeon did not know whether or not it was in

e chest. If it was inside that person would die of rcinoma, whatever operation might be performed. feature of the report was the number of cases in iich a local operation had been done, and at a later ge—sometimes as long as two years afterwards—a lical operation had been performed. Thirty years o Sheilds had produced tables of cases extending ny years back and had shown that many patients vived after only a small local operation. Some ars ago Mr. Fitzwilliams had operated on a very vous patient, and had promised her he would do y one operation ; he believed her to have mastitis. had found, however, that the breast contained a lule of carcinoma and he had left her with much xiety. That was four years ago and she had had hing else done ; she was still well. In operating cases of chronic mastitis he had found 20 in which re was a carcinomatous nodule, but only three of m had been lost, one as the result of an accident. did not believe infection took place from gland to nd, but from primary growth to successive glands. had had breasts X rayed before operation and ayed after operation, but he could not say he had n good come of it, nor had he seen the bad sequelæ n the rays that some speakers referred to. He had greatest respect for radium, but it must not be d in conjunction with the operation, as it would ay healing, and might cause a bad and stubborn n.

Mr. V. WARREN LOW said that the committee had sen ten years as the period after which cure seemed ave been effected because a less period was not so for generalisation. If the period were extended to or 20 years this would bring the patients to a stage which they were liable to die of anything, cancer g a disease of middle and late middle life.

Mr. ZACHARY COPE raised the question of how ny cases would have survived without operation. cer was either long-lived or short-lived, as were ple. When the natural incidence of death was en into consideration the report was more favour- than it appeared to be on the surface. And as s recurred after 20 years could it be said that er was ever cured ?

Mr. DONALD ARMOUR said that when Mr. Miles ared that surgery had done but little for these cases ould not have sufficiently considered what these ents suffered from their disease in pre-operative s. A very important matter was the resistance of individual to the cancer cell ; another was the ver to the question " How long have you noticed mp ?" The West London Hospital had been the to take up the Erlangen treatment for carcinoma e breast, and the report issued, based on the work he entire staff, had stated that no case could be ten down as either improved or cured by X ray ment.

Mr. W. E. TANNER proposed a cordial vote of thanks he Committee for their labours, and this was ed with acclamation.

ITCHELL BANKS MEMORIAL LECTURE.

r BERKELEY MOYNIHAN delivered this lecture he University of Liverpool on Nov. 24th, his ect being

The Gall-bladder and its Infections.

r speaking of the functions of the gall-bladder, activity of its mucosa in concentrating bile, and ethods of emptying, he declared that whatever bject of these processes it was probable that the important functions of the gall-bladder were ected with the alimentary canal. He briefly issed the subject of primary infections in order evote himself fully to the origins, channels of oach, and local results of secondary infections. n instance of infection by way of the blood, ferred to typhoid septicæmia, with its consequent ucous focus of inflammation and later involvement of the interior of the organ. As regards lymph-borne infection, he laid stress on the frequency with which a pre-existing hepatitis was found, from which apparently a lymphangitis spread to the outer layers of the gall-bladder ; thence inflammatory products and destructive changes could be traced through the muscular coats into the submucous tissues. Infection of the mucosa followed, and the fully developed stage of the disease was reached. He believed that this was the commonest channel of infection. Ascending biliary infection had been derided, but he had found in three of his cases a minute piece of metallic copper, in another a tiny ball of thread, in the core of gall-stones where no direct communication existed with the bowel. This must be taken to confirm the work of C. J. Bond, of Leicester. If organisms were to make their way up from the duodenum, of necessity changes must have taken place in the reaction of this part of the alimentary canal, normally sterile. This assumption was strengthened by the discovery that 22 per cent. of patients with gall-stones had complete achlorhydria. No doubt in other instances infection descended from the liver in the bile. This, of course, presupposed the existence of a septic focus somewhere in the portal tract, often in the appendix. There was, however, another part of the portal venous system which must be kept in mind. In certain conditions of the blood the spleen discharged enormous quantities of bilirubin-calcium into the portal vein, and this seemed to be excreted in the bile ; at least bilirubin calcium was found forming the core of quite a number of calculi. It might be that in the future it would be necessary to deal with the spleen in order to cut off the supply of this calculogenic material. In cases in which the trouble seemed to originate in the mucous membrane, cholesterol was deposited in enormous amounts in the mucous and submucous tissues. A polypoid condition developed, and when the pedicle ruptured, as it very easily might, a foreign body was set free, round which further cholesterol was soon deposited. He believed that calcium was deposited only after the erosion of the mucosa at the site of impaction of a stone or for other reasons, and was evidence of further infection.

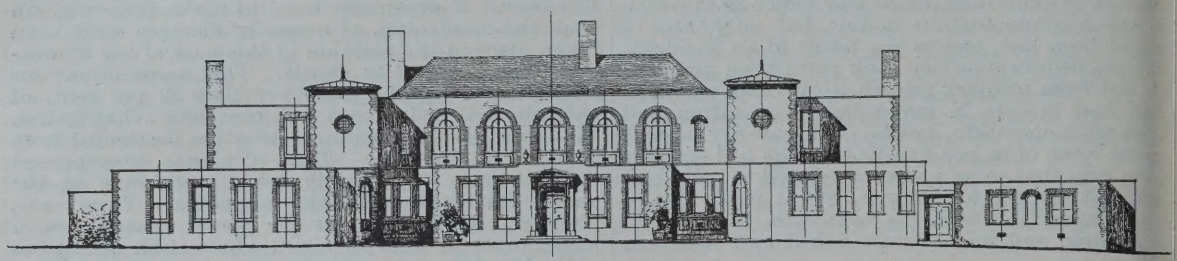
A series of microscopical slides was shown, illustrating primarily the lymphatic origin of cholecystitis secondary to hepatitis. Among important observations mentioned were the thickening of the nerve-fibres in the subserosa, suggesting the histology of " stump neuromata," and the complete absence of polymorphs among the exfoliated columnar cells in most cases of the disease. Case after case was described in which radiography of the excised gall-bladder and its contained stones had demonstrated their structure and composition. In conclusion the lecturer pointed out the value of the negative result in the Graham technique of radiographic investigation, and said that in many cases of cholecystitis the naked-eye changes in the gall-bladder were hard to appreciate. Knowledge of these facts, and a careful study of clinical histories, would, he hoped, make it possible to bring cholelithiasis into the category of preventable diseases.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society held on Nov. 24th the following office-bearers were appointed : President, Dr. Thomas Fraser ; Vice-President, Prof. Alex. Low ; treasurer, Dr. Robert Richards ; secretary, Dr. Harold Edgar Smith ; editor of transactions, Mr. George Herbert Colt ; librarian, Dr. Middleton Connon ; assistant secretary, Dr. John Craig ; recording secretary, Mr. Andrew Fowler. Members of Council : Dr. William Brown, Dr. John F. Christie, Dr. James Crombie, Mr. Andrew Fowler, Mr. Alexander Mitchell, Dr. Henry Peterkin, Dr. George Rose, Dr. James A. Stephen, and Dr. George Williamson.

NORTHERN INFIRMARY, INVERNESS.—Mrs. Mackintosh of Mackintosh last week cut the first sod in preparation for the extension and reconstruction of the Northern Infirmary, which is to cost £100,000. Over £70,000 has been raised in two years.

EPSOM COLLEGE SANATORIUM.

THE Sanatorium has been designed as a two-storey building of red brick, with quoins and window dressings of red brick of a richer colour. The central portion will have a sloping roof, the remainder of the building having flat roofs covered with asphalt. All the wards will face south and ample provision is made for wheeling the beds into the open air. Low-pressure central heating by means of radiators will be used throughout the building, independent boilers being provided for the domestic hot water-supply. The wards in addition to radiators will have open fireplaces.



ELEVATION TO COLLEGE ROAD

Electric lighting will be installed and cooking will be by gas. The floors of the wards will be of battleship linoleum laid on a cement screed and laid flush with a coved border and skirting in cement, while the corridor floors will be of asphalt laid in a similar manner. Gauged plaster, with a final coat of "sirapite" or similar patent plaster will be used throughout the building.

The boilers for the central heating and domestic hot water-supply and the disinfector for clothing and bedding will be placed in the basement below the kitchen wing. Food for both isolation and non-infectious wards will be supplied from the main kitchen, a diet lift being installed to the first-floor wards.

The building has its long axis running east and west with a centrally placed main entrance on the north side opening into a hall. To the right of the hall is the nurses' dining-room and beyond this the kitchen wing, with servants' hall, and quarters for a married couple to act as cook and porter.

To the left of the entrance hall is a simply equipped operation room and beyond this again the out-patient wing, approached either from the corridor or by a separate outside entrance, through which stretcher cases can be wheeled direct to the wards. Rooms for the medical officer and matron, waiting, casualty, and X ray and massage rooms, are conveniently arranged. At either end of the main corridor a 16-bed ward projects south, forming with duty room, bath-room, sanitary annexe, and nurse's bedroom a complete unit. Separating these ward units and opening direct into the main corridor are four single-bed wards and a dining- and recreation-room, and so forming three sides of a square, the fourth or south side being ope The large 16-bed ward at the east end of t corridor is an isolation ward shut off by doub doors from the rest of the sanatorium and which the only access for patients is by a separa external door. All the other wards on the grou floors with a total of 20 beds are reserved for no infectious cases.

The first floor is approached by two staircas one opening out of the ground floor corridor the west end leads to the staff bedrooms, whi the other leads from the lobby of the isolati ward to the first floor wards, consisting of one eig bed ward, one four-bed ward, two single-bed war and a small dining-room, making with the 16 be on the ground floor a total of 30 beds for infecti cases.

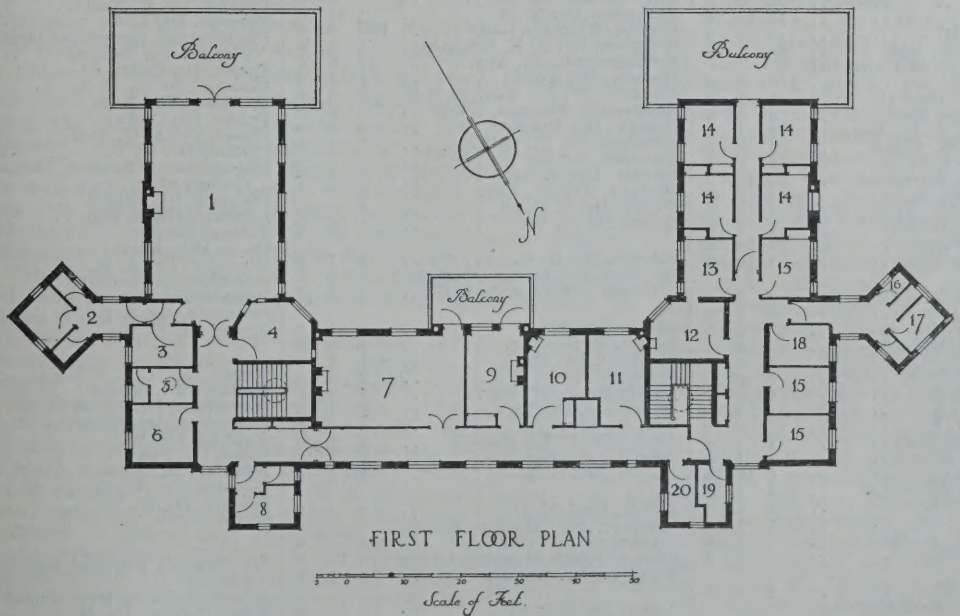
ation.—1. Ward and solarium (16 beds). 2. Duty room. 3. Staircase to first floor, isolation wing. 4. Nurse. 5. Bath-room. 6. Sanitary annexe (lavatory, sink-room, w.c.'s, and soiled linen).
atorium.—7. Ward and solarium (16 beds). 8. Duty room. 9. Nurse. 10. Bath. 11. Sanitary annexe (lavatory, sink-room, w.c.'s, and soiled linen). 12. Single-bed wards. 13. Dining- and recreation-room. 14. Operation-room (staff lavatory adjoining). 15. Nurses' dining-room (patients' lavatory adjoining). 16. Bath for patients in single-bed wards (cleaner adjoining). 17. Kitchen. 18. Scullery with larders and store adjoining. 19. Linen- and mending-room. 20. Mattress store. 21. Staff dining-room. 22. Married couple's room. 23. Bath-room and w.c. adjoining. 24. Soiled linen. 25. Boots (w.c. adjoining). 26. Wood and coal store. 27. Cleaner for isolation section. 28. Medical officer. 29. X ray dark-room. 30. X ray room. 31. Dispensary. 32. Matron's office. 33. Casualty and dressing-room. 34. Waiting-room with lavatory adjoining.



Isolation.—1. Ward of eight beds. 2. Sanitary annexe (sink-room, w.c., lavatory, and soiled linen). 3. Bath-room. 4. Duty room. 5. Nurses' bath-room and w.c. 6. Nurses' room. 7. Ward of four beds. 8. Sink-room (patients' w.c. adjoining). 9. Single-bed ward. 10. Single-bed ward. 11. Dining-room with diet lift adjoining. *Staff.*—12. Matron's sitting-room. 13. Matron's bed-room. 14. Nurses' bed-rooms. 15. Domestics' bed-rooms. 16. Domestics' w.c. and cleaner adjoining. 17. Nurses' bath-room and w.c. adjoining. 18. Domestics' bath-room and lavatory 19. Box-room. 20. Bath-room for small wards.

LIST OF CONTRIBUTIONS.

The following is a list of contributions to the new Epsom College Sanatorium Fund :—

Reviews and Notices of Books.

E COMMON DISEASES OF THE SKIN.

A Handbook for Students and Practitioners. By R. CRANSTON LOW, M.D., M.R.C.P., Lecturer on Diseases of the Skin, University of Edinburgh; and Physician to the Skin Department, Royal Infirmary. London and Edinburgh: Oliver and Boyd. 1927. Pp. 223. 14*s.*

THE scope and composition of this handbook, its se and dogmatic style which has by no means bed it of a certain literary excellence, and, above a valuable and discreet selection of life-like strations and textual figures and diagrams, have bined to produce the most noteworthy contribu- n of its kind in recent years. As might have been ected from the author of "Anaphylaxis and sitisation," the chapters on eczema, urticaria, and eruptions in which sensitisation plays a part, are ticularly interesting, and even the expert will in them certain hints and explanations for which will search many larger text-books in vain. Com- dable, too, are the sections on vesicular and ous eruptions, and the attention of the casual er will be held by such phrases as "all pemphigus s show bullæ, but not all bullous eruptions are phigus." The relationships of herpes zoster and cella, and the ætiology of alopecia areata are ly discussed, some original suggestions being forward. If it should be argued that theory is out place in a handbook, the reader will certainly fit from the occasional lapses that make for rest and save the work from being a catalogue. little diagrams showing the relative dermal and ermal situations of cheloid and hypertrophic s should help to prevent the common error of using these conditions.

reatment is modern in every section and will e a general appeal on the score of simplicity. vas perhaps hardly necessary to describe the il of radiotherapy for ringworm of the scalp, the bulk of dermatological opinion would not e that "if there is only one spot of disease which ar the scalp margin then that spot and a wide around it should be X rayed." If X rays are led upon, epilation should be total. Thallium te treatment, which is not even mentioned by Low, may eventually displace X ray epilation ely. Syphilis and syphilitic eruptions, it should oted, are not dealt with, except in so far as ential diagnosis is concerned.

e book contains 68 illustrations and 49 full-page s, eight of them in colour. These and the ing itself are excellent, and the relatively low should add considerably to the many attractions e book.

PHYSICAL SIGNS IN CLINICAL SURGERY.

By HAMILTON BAILEY, F.R.C.S. Eng., Surgeon, Dudley Road Hospital, Birmingham. Bristol: John Wright and Sons, Ltd. 1927. Pp. 217. 21*s.*

MANY small books in surgery have been written for students beginning clinical work, but none of them is quite of the same character as this. It is a treatise on examination of the patient by palpation, percussion, and other simple clinical ways on the same lines as Prof. F. Lejars's well-known book, only it is smaller and therefore better adapted for the use of junior students. It was time a book of this nature was available in English, and the author is to be congratulated upon the success with which he has carried out his task. A feature of the book is the abundance of illustrations, all of which, in addition to the excellence of reproduction, are informative. The text is usually terse and to the point, and the mnemonic for urinary complaints from "As You Like It," on p. 153—which is simply ingenious without being any aid to the memory—is the only blemish upon a very good and otherwise serious addition to English surgical literature.

THE NORMAL CHEST.

The Normal Chest of the Adult and the Child. By J. A. MYERS, Associate Professor of Medicine, University of Minnesota. In collaboration with S. MARX WHITE, R. E. SCAMMON, A. T. RASMUSSEN, C. A. STEWART, and GEORGE E. FAHR. London: Baillière, Tindall and Cox. 1927. Pp. 419. 22*s.* 6*d.*

A COURSE of study of the normal chest at Minnesota University, begun in 1921, forms the groundwork of this book. A brief account of the anatomy and physiology of the normal chest precedes a really excellent description of the physical examination, while Chapter 8 deals with the importance of systematic scrutiny of this sort. The author repeatedly emphasises the necessity of studying the various physical, X ray, and other signs which may be found in the normal chest, and his view is reasonable that much time should be spent in learning the normal breath-sounds, areas of dullness, and so forth, before the study of disease is undertaken. In the hospitals, students are apt to concentrate on disease, and there is no doubt that the teaching of the normal and the varieties of the normal is much neglected. This book therefore supplies a real want, although for the student overmuch space is given to detail; the last three chapters, for example, deal in 150 pages with the innervation of the chest, developmental anatomy, and acoustics in a way that can only be of interest for the specialist. Chapter 5, contributed by Dr. White, deals with the examination of the heart and great vessels, and Dr. Stewart describes the normal chest in infancy and childhood. Copious references are conveniently arranged at the end of the chapters.

We can thoroughly recommend this book, and shall look forward to volumes dealing with the normal in other systems of the body.

THE ALPINE CLIMATE.

Der heutige Stand der Physiologie des Höhenklimas. By Prof. Dr. LOEWY. Berlin: Julius Springer. Pp. 60.

IN this short account of the present state of alpine physiology the author correlates results obtained by many investigators, among whom he occupies a distinguished place. The first part of the book contains observations on the special factors which distinguish the climate of mountains and high valleys; the second part deals with their effects on physiological processes, especially circulation, respiration, and metabolism. Dr. Loewy analyses the action of the various elements of the solar radiation and confirms the value of natural sunlight as compared with artificial sources of light, although the more the spectrum of the latter approaches that of the sun the greater the similarity of its action. He recalls the work of Sonne, who showed that while a source of ultra-red rays (a heated metal plate) may raise rapidly the skin temperature and cause a sensation of burning, though at a depth of 2 cm. the temperature remains normal, exposure to the sun's rays for half an hour causes much less elevation of surface temperature but a marked rise in the deeper tissues. This he considers to be an important factor in raising the bactericidal power of the blood. The increase of metabolism caused by a sojourn in the mountains he attributes to several factors, but chiefly to the stimulation of the skin by the air and solar rays. Alpine therapy has been well established on an empirical basis, but Dr. Loewy's concise and lucid study is a real contribution to scientific therapy.

Das Strahlungsklima von Arosa. By P. GOETZ. Berlin: Julius Springer. Pp. 110. M.8.70.

THIS monograph contains a mass of data and some interesting speculations on the climate of the Swiss Alps as observed at Arosa. The author refers to the well-known fact that in the Alps the average temperature in winter does not fall with increasing altitude as rapidly as would be expected. An important cause of this phenomenon is the collection of cold air and mist over the lower regions with upward reflection of heat and light waves from the surface of the sea of cloud thus formed. These favourable conditions are accentuated at Arosa owing to its situation on a slope facing south. This gives a higher average winter temperature than would be found at the same altitude at the bottom of a valley. After sunset the slope loses heat by radiation, but the cold air flows down to the bottom of the valley where it forms a pool of very low temperature, its place being taken by a falling evening current of only moderate temperature. Another point of general interest which Dr. Goetz brings out is the ratio of horizontal to vertical light. The former is defined as the amount of light falling on a vertical plane facing south—e.g., a window. In winter the possible duration of sunlight per day is relatively short, but owing to the low level of the sun the horizontal component of it is so much increased that the actual amount of sunshine entering a room is as great in winter as in summer. This surprising result is also due in part to the fact that clouds are more frequent in the summer months. Thus the ratio of overcast days in January, as compared with July, is as 1 to 1·8.

SOUTH AMERICA.

By FRANKLIN H. MARTIN, C.M.G., D.Sc., M.D., LL.D., F.A.C.S. London: Fleming H. Revell Company. 1907. Pp. 435.

Dr. Franklin Martin, the well-known Director-General of the American College of Surgeons, has brought together in this book a valuable mass of information upon the Latin American countries. The notes were made or collected during visits to those countries on behalf of the American College of Surgeons, and they include experiences met with aboard the *Ebro* in a tour which included Jamaica, Panama, Peru, Chile, Argentina, Uruguay, Brazil, Ecuador, and Bolivia. Various sections are a contributed by Dr. A. J. Ochsner, who visited so of the larger cities of Mexico, and Dr. E. I. Salisbu who records experiences in Nicaragua and Cu All the information is directed towards introduci to the medical profession of the rest of the wo the progressive course of their sciences in La America. It is simply given, and profusely illustrat while the rapid development of medicine in some the countries visited, especially those most regard in Europe as backward States, will come as a surpr to many readers. During Dr. Martin's visits to So America and Panama in 1921, 1923, and 1925, personally interviewed the Presidents of Panar Peru, Argentina, Uruguay, and Brazil in regard establishing, presumably in Panama, a memorial William Gorgas. This is to take the form of Institute of Tropical and Preventive Medicine, and President Coolidge, the honorary president of movement, is deeply interested in the scheme, practi outcome will not be delayed.

MENTAL HANDICAPS IN ART.

By THEO. B. HYSLOP, M.D., C.M., F.R.S.E. W a foreword by ARTHUR THOMSON, Professor Anatomy, Royal Academy. London: Baillie Tindall and Cox. 1927. Pp. 98. 3*s.* 6*d.*

WITHIN less than 100 pages this little book conv much æsthetic information, much useful critici and much sound philosophy. The exposition of true aims and objects of art leads up to chapt dealing with the appropriate union of arts and indus and with the right appreciation and employment the artistic faculty. Readers recognising in author a well-known psychologist, as well as accomplished artist, will turn naturally to the c cluding sections on the influence of disease upon and the possible connexion of toxins with arti production. Dr. Hyslop suggests that m hysterical, hyperæsthetic, or supernorm sens anomalies are in reality merely reversions to rem acquirements in evolution. He finds evidence t "what we have lost in instinct we have gaine reason," and appraises some of the most ex ordinary developments of the special senses as reality not instances in advance of the evolutio those special senses, but rather examples of rever to more primitive conditions of biological evoluti Not infrequently, he states, such abnormalities appear when the balance of the internal secret becomes readjusted. And on the often deb question of how far genius and madness are he finds that: "With the formidable array evidence of degeneration in those who are ackn ledged to be geniuses in art, the theory of ge being a disease of the nerves is apt to gain gro but not when we take balance as the test of me health." He warns us that degeneracy is o productive of bad art. A touch of madness serve in some instances to raise the individual a mediocrity, and bad or offensive art is not invari a symptom of degeneracy, for it may be the r of defective education, failures in observation technique, or of imposture. There is much th timely in these words.

Messrs. J. and A. Churchill inform us that the p of Rowlands and Turner's "Operations of Surge reviewed in THE LANCET of Sept. 17th (p. 610 £3 10*s.* for the two volumes.

COÖRDINATION OF BRISTOL HOSPITALS.—It has decided by the council of the Lord Mayor's Hospital and the local Voluntary Hospitals Committee to appo Committee of Inquiry to consider the extension of ac modation, and the best means of preventing overla and securing coördination. There are 15 hospita Bristol with approximately 2100 beds, many of whic doing precisely similar work. Three of them have rec made urgent appeals for help; another is being fin to a substantial extent by the corporation, and two ones are about to be built.

THE LANCET.

LONDON: SATURDAY, DECEMBER 3, 1927.

PSOM COLLEGE: THE NEW SANATORIUM.

WE publish this week the results, as they at present and, of the efforts made by the Council of Epsom ollege for providing the institution with a new and lequate sanatorium. The intention of the Council as made known in these columns and in many other urnals in December last, and the outcome of that reliminary notice has warranted the Council in roceeding to definite plans in respect of site and nstruction. All who know anything of the cost per ed which has to be met in the founding of a modern edical institution will see that the substantial sum ready subscribed bears small relation to the sum hich will have actually to be spent, for thrice that m is needed to warrant a start, and a total far higher ill eventually be required; but it will be remembered at so far the subscriptions have been made largely the dark, for, while the statement of the Council at the new structure was required has been cepted, no one could have known until now exactly e way in which it was proposed to spend the money btained. We hope and believe that, with the detailed ans before them, which by the help of the accomnying descriptions are easy to follow and appreciate, large number of our readers will resolve not only to ke a share in the good work, but to urge upon their tients and friends the righteousness of doing the me. Epsom College possesses public as well as ofessional claims, and the list of subscriptions blished to-day shows that in many directions these ve been finely acknowledged.

The story of Epsom College is one of steady velopment. There is no question of bolstering up institution which is not justifying its existence; ther, pecuniary support is asked because the work ne has been so progressive, and because that work s never proved itself of greater public value than day. Three-quarters of a century ago we find that an early reference to the foundation of the College, prophesied its great future, and the steps in its ogress, as they have been recorded regularly in our umns, have been associated with expenditure by e Council of large sums of money. Epsom has never ted on its laurels, but always, as it obtained success, s prepared for still greater success. In the extension buildings, the provision of needed improvements for e comfort of boys and staff, the erection of laboraies, lecture rooms, common rooms, and chapel finite evidence has been supplied by the authorities their sense of growing responsibilities. The need w is one which should have a particular appeal to dical men, for it is an anomaly that a great public ool, definitely associated with medicine, should be nd behindhand in any arrangements for the medical atment of its charges. Now there is no doubt that e new sanatorium is urgently required. The number beds projected may seem large, but this will not be e opinion of the school authorities, nor of any who ve realised the difficulties which epidemic disease ails upon residential institutions like great boarding ools. The provision for sickness in all our large blic schools, if the tenets of modern medicine are being observed, will always appear prodigal while there is no particular reason for the occupation of the beds; alas, it may often be found too small if the school should be unfortunately visited by an epidemic of any extent or virulence. The Council of Epsom in placing the figure of beds required at 50—30 general and 20 isolation—for an estimated total of about 400 boys, have adopted the accepted view of experts.

The cause of Epsom College has been pleaded so often and so regularly in these columns that anything said now will assuredly have been said before. This does not mean that it should not be said again. The school provides a first-class general training, with amenities for study and for sport that make it comparable to any of its similars in the country. It also supplies a magnificent opportunity for giving these advantages to the children of medical men whose expectations of educating their offspring suitably have been destroyed by death, sickness, or misfortune. The plea for money needs no further justification. It is to be hoped that the present appeal will enable the authorities of the College to proceed at once to develop their far-seeing scheme.

SURVIVAL AFTER OPERATION FOR BREAST CANCER.

THE investigation of disease by a body such as the Medical Society of London is not without precedent, although it is unusual for such a body to overcome successfully the inertia in its make-up. It is with genuine pleasure, therefore, that we welcome the report presented to the Society on Monday last upon the late results of operation for carcinoma of the breast The report is summarised on p. 1181, along with a brief account of the discussion to which it gave rise. To assess the value of an operation in relation to the survival ratio after the lapse of a considerable number of years is never easy. Yet it is obviously of immense importance to find out whether carcinoma of the breast is better treated by the simple operation of local removal or by the severe and mutilating "radical" operation, or whether it would be for the greatest good of the greatest number if no operation were performed at all. Carcinoma of the breast is one of the commonest forms of cancer, and, although it is anatomically one of the most accessible, the results of operation have not seemed to be correspondingly good. If patients are to be persuaded to present themselves for operation at an early stage, an effort must at least be made to prove that operation really is efficacious. It must not be merely a genial faith in the mind of the surgeon. By far the most extensive investigation of the problem that has ever been carried out was done by Dr. JANET LANE-CLAYPON, and was published by the Ministry of Health in 1924.[1] Probably it would be impossible for a voluntary society to gather any comparable mass of data. The committee of the Medical Society of London have pointed out, however, that all investigations hitherto published have, for various good reasons, taken a three-year, or at most a five-year, survival period as the evidence of cure after operation. The committee which drew up the report have endeavoured to strike out in a new line by restricting their investigations to those patients who have survived operation for ten years or more, and of these they have gathered 265 records.

[1] Reports on Public Health and Medical Subjects, Nos. 28 and 32. H.M. Stationery Office, 2s. 6d. and 3s. THE LANCET, 1924, i., 1074.

This deliberate restriction of the field has inevitably resulted in limiting also the value of the investigation. Statistics based on so small a number can contribute little or nothing to the answering of the larger questions which Dr. LANE-CLAYPON has already surveyed from a basis of 20,000 records. Comparative results, in fact, cannot be obtained at all from an arbitrarily selected class such as this, since there are no other categories with which to compare them. The chief value of the work done seems, indeed, to lie in the unequivocal demonstration of the fact that so many records of ten-year survivals can be gathered and can pass the most careful scrutiny. This must necessarily bring encouragement to every woman who finds that she is a sufferer from the disease. Another fact of great interest which has been brought out is that no patient or surgeon need despair, even in the face of recurrence of the growth. No less than ten patients were alive and well from 10 to 21 years after the primary operation, although they had had one or more secondary operations for recurrence. One had even had a recurrence of the growth in the skin over the lumbar spine. The Medical Society of London may therefore be congratulated on having furnished a very real message of hope to those engaged in the war against cancer. They have also provided an example of careful investigation which, it is to be hoped, is but a first instalment and which may be emulated by other bodies of medical men.

MEDICAL CONFIDENCES.

LAST week, with the aid of sponsors from various political parties in the House of Commons, Dr. E. GRAHAM LITTLE introduced the Medical Practitioners' Communications Privilege Bill, which was read a first time. A summary of Dr. LITTLE'S introductory speech was given in our Parliamentary Intelligence (p. 1161). Discussing the Bill in its issue of Nov. 19th, the *Solicitors' Journal* remarks upon the need of foreseeing that the privilege, if granted, shall not be stultified by liability to adverse comment in court when the privilege has been exercised. The point is well taken. Let us suppose that a medical witness is asked a question which involves answering whether the patient was or was not being treated for some form of venereal disease. If the witness replies, "I claim professional privilege and I decline to answer," it is easy to see that such a reply may set up an inference which is tantamount to disclosure. The doctor's professional privilege, observes the *Solicitors' Journal*, if given, should be exercised as a matter of course, and the jury should not be allowed to form an adverse opinion against the patient by reason of its exercise; indeed, it may be argued that a doctor should not waive it even at the request of the patient, for, if this became the practice, those patients who did not make such request would naturally be regarded as having good reason not to do so. It is not in all respects easy to assimilate the professional relationship of doctor and patient with that of solicitor and client. Doctors are called upon every day to give evidence on behalf of their patients—for instance, to estimate the damage caused to the victim of a street accident when some collision in traffic is alleged to be due to the defendant's negligence. If in a libel or slander action the defamation consists of a statement that the plaintiff is suffering from venereal disease, how can he disprove the statement without the evidence of his doctor? Adverse comment is not allowed if a legal adviser claims professional privilege. In Wentworth *v.* Lloyd (1864, 10 H.L.C. 589) objection was taken to the disclosure by a New South Wales solicitor of information which he had obtained in the course of his professional employment. The then Master of the Rolls was inclined to let the objection weigh against the party taking it; he regarded the refusal to allow the answer as a keeping back of evidence equivalent almost to keeping a material witness away from the court. Lord CHELMSFORD protested strongly against this view "so entirely at variance with principle and so utterly in contradiction to the well-known and invariably recognised privilege of professional confidence. . . . A person who refuses to allow his solicitor to violate the confidence of the professional relation cannot be regarded in that odious light." Lord BROUGHAM, it may be recalled, explained the rule of the solicitor's privilege by saying that the course of justice would stop if no such rule existed; "no man would dare to consult a professional adviser with a view to his defence or to the enforcement of his rights." The exclusion of such evidence, said Lord Justice BRETT, is a rule established upon grounds of public and general policy. The medical profession has to base its claim upon the same ground of public interest. It can say with truth that, in the campaign against racial diseases, early recourse to medical advice and treatment is essential, and that public policy demands that no man be discouraged from prompt and confidential consultation with a doctor. Health is hardly a less urgent national need than justice.

EPIDEMIC POLIOMYELITIS: ITS POSSIBLE TRANSMISSION BY MILK.

IN the autumn of 1926 public attention was directed to the problem of acute anterior poliomyelitis, largely because of its sudden occurrence in certain educational communities, and also because of the controversy which then arose as to the propriety of school closure with the object of controlling such outbreaks. It may be well to recapitulate briefly the facts recorded by Dr. A. M. WATT, medical officer of health in one of the districts affected. Until Oct. 14th no notifications of poliomyelitis had been received during 1926, but on that day 13 notifications reached the health department and others followed in rapid succession until Nov. 11th 62 authenticated cases had been notified and information had been obtained of five other patients who sickened elsewhere but acquired the infection in the district—a total of 67 cases. The salient features of the epidemic as they presented themselves to the medical officer of health may conveniently be set out in his own words [1]:—

"(1) That the disease was limited mainly to the children attending private schools in the district, particularly boarding schools; that most of these schools were situated in the northern part of the district, and that the private schools had very little communication with each other.

"(2) That the disease started almost simultaneously in all the schools affected, and that the outbreak ceased almost entirely at the end of a fortnight.

"(3) That the disease did not spread to the adjoining districts.

"(4) That the disease did not spread in the elementary schools."

The unusual character of the epidemic could hardly be better stated; nevertheless, both the loca-

[1] Brit. Med. Jour., 1927, i., 114.

ealth department and the Ministry's officers regarded he behaviour of the disease in this case as con-rming the generally accepted view that transmission ccurs from case to case or through the agency of ealthy carriers. The probable mode of spread is iscussed at some length in the annual report for 926 of the Chief Medical Officer of the Ministry, which 74 cases are recorded as belonging to this idemic. The sudden onset is tentatively explained y postulating a rise in the carrier-rate "until it ached a point at which the virus became actively rulent in a susceptible juvenile population"; nd it is surmised that the sudden ending was due the activity of the preventive measures adopted. n these points our only comment is that such ccess in controlling by administrative methods an utbreak which might be regarded as the boiling er of a simmering pot of carrier-infection strikes as unusual. Since brief but adverse reference as made in that report to the theory that the fection might have been conveyed by milk, it is sirable to direct attention to an article [2] on the utbreak by Dr. W. L. AYCOCK, of Harvard, U.S.A. The epidemiological criteria by which a milk-rne infection may be identified may briefly be ated as follows: (1) epidemiological or bacterio-gical evidence that the disease in question is trans-issible by milk; (2) suddenness of onset; (3) a ilk-supply common to a preponderating majority the earlier cases; (4) the presence of a sufficiently ge community of persons who are not consumers the suspected milk to serve as controls; (5) the sence of any obvious link between the earlier cases her than the milk-supply; (6) an unusual age-stribution of the cases; and (7) the demonstration a source from which the milk might have been ely to be contaminated. It is rare indeed that all ese criteria can be satisfied, generally the last them being the most difficult to meet because of e inevitable delay in prosecuting inquiries of this d. Incidentally it is well to remember that lk epidemics are not always sudden in onset. ey may also occur, and indeed are most liable to ur, when case-to-case infection is rife in any area, that their presence is apt to be masked. The earliest lk-infected cases are rarely the first local cases of e particular disease involved. Dr. AYCOCK, who ited the district to investigate the circumstances the outbreak, refers to previous instances of polio-elitis which he believes to have been milk-borne. ter sifting the information which he obtained, he has ived at the conclusion that the epidemic in question s milk-borne. He has traced 75 cases (the difference tween his and the Ministry's figures from those en by Dr. WATTS no doubt being due to the late covery of some cases, a common feature of out-aks of poliomyelitis), of whom 43 showed definite ralysis, 29 no paralysis, and 3 were doubtfully ralytic. Obviously the diagnosis in the first up must be much more certain than in the others, al special weight is therefore attached to their edemiological history. It is shown that 35 of these ained milk from one dealer, who may be called ler A, while the remaining 8 were on the supply of other, dealer F, who was known to have overcome emporary shortage of milk by purchasing about gallons daily from dealer A during the period when most of the cases must have been infected. The majority of the non-paralytic cases were also among the consumers of these two supplies, but six cases of this type or of doubtful character were not definitely associated with either of them. The importance of these latter exceptions depends on several factors—viz., the order of their occurrence in the epidemic, the finality of the diagnosis, and definite establishment of the fact that they never, even casually, consumed either of the suspected milks during the period in question (for instance, in the form of ice-cream). Apparently some of these points must remain doubtful. Dr. AYCOCK's table setting out the size of the various milk rounds and their connexion with the cases is reproduced here for the sake of clarity.

Dealer.	Daily supply.	Total cases.	Paralysed.	Non-paralytic.	Unknown.
A	1080–1200 quarts.	50	35	14	1
B	1000 quarts.	1	0	1	0
C	250 ,,	1	0	0	1
D	150 ,,	1	0	1	0
E ..	Tinned milk used to considerable extent by poorer classes.	1	0	1	0
F ..	500 quarts. (Purchased an average of 44 quarts daily from A from Sept. 23rd to Oct. 15th).	19	8	11	0
G	200 quarts.	0	0	0	0
H	Small.	0	0	0	0
I	,,	0	0	0	0
Unknown	—	2	0	1	1
Total	—	75	43	29	3

It is important to note that there are serious discrepancies between the Ministry's report and Dr. AYCOCK'S paper in relation to certain salient facts. The former attaches little importance to previous instances of milk-borne poliomyelitis. Further, it states that three dealers were almost entirely responsible for the milk-supply of the district, presumably the two described above as A and F, and a third whose supply was apparently regarded as negligible. If this were so, and if the Ministry's statement that the majority of persons in the area who did not contract poliomyelitis also obtained their milk from the large dealer associated with most of the cases (presumably the one described here and by Dr. AYCOCK as dealer A), then, of course, the milk connexion would be a coincidence. The table, however, which we have reproduced from Dr. AYCOCK's article, indicates that there were other important dairymen in the area, and that, even if most of them operated in a neighbouring detached district, still the immunity of the customers of dealer B, who appears to have delivered milk on a large scale in the affected district, requires to be explained. Again, Dr. AYCOCK and the Ministry both use the term "abortive cases," but the former appears to mean by this term non-paralytic cases, while the latter can hardly use the term in the same sense, since they chart only 8 cases as abortive, although one must infer from Dr. WATTS'S report that 33 of the 62 notified cases were regarded locally as having had no paralytic manifestations. Some of these showed signs of encephalitis. Certain individual cases to which Dr. AYCOCK refers are of special interest. In one school where there were 28 boarders, five boys, by special arrangement, received bottled milk purchased from dealer A by dealer F, and delivered to the school by the latter. The only two cases in the school occurred among these

[2] The American Journal of Hygiene, November, 1927, p. 91.

five boys. Again, four temporary visitors to the district, all staying in different houses, but consuming dealer A's milk, sickened away from the district at or about the same time. Apart from their milk-supply no common link could be discovered, and the fact that the period during which they were all residing in the district covered three days about a fortnight earlier accords with Dr. AYCOCK'S view that the incubation period is long rather than short. On the other hand, the Ministry's report appears to accept the view that the incubation period of poliomyelitis is usually short, and their theory of case-to-case, or carrier-to-case, infection hangs partly on this view. Here, then, is another crucial question that requires settling.

There are weaknesses in Dr. AYCOCK'S chain of evidence, of which the most important is his failure to trace the infection back to any particular producer, either by means of circumstantial evidence or by the discovery of an infective case among any farm household or staff. We understand that his visit was a brief one, and it is rather unfortunate that more time was not given to this important part of the investigation. It may take weeks to elicit all the information relevant to a milk-borne epidemic. The details given of dealer A's operations are somewhat conflicting; it is suggested that his Grade A supply may have been implicated, but it is not shown that dealer F had contracted for a supply of Grade A milk from him, and it appears unlikely that dealer A would sell his best milk to a rival as ordinary commercial milk. More use might have been made of some of these facts, and such other phenomena as the complete immunity from the disease of a large school receiving milk only from dealer A, to narrow down the number of farms possibly involved. Yet those who have frequent dealings with the milk trade are well aware of the difficulty in threading its ramifications. The report of the Chief Medical Officer exhibits a striking difference in the age-distribution of the epidemic in question, as compared with other outbreaks in 1926, or, indeed, with the generality of epidemics. Only 25 per cent. of the patients were under 10 years of age, against the usual percentage of 80 or 90. It is natural to explain this by the fact that the schools affected contained children whose ages were mainly over 10, but Dr. AYCOCK claims that the proportion of cases under 10 among persons outside boarding schools was just over 50 per cent., which is still very low.

Examining Dr. AYCOCK'S views in relation to our criteria, we find his contentions to be that the epidemic tallied with a milk outbreak in its suddenness, in an incidence which was mainly on the consumers of a single milk-supply, in its unusual age-distribution, and in the somewhat equivocal and remote character of the other connexions between many of the cases occurring almost contemporaneously. The controls, according to Dr. AYCOCK, were sufficient in volume to remove any suspicion of coincidence; according to the Ministry they were not, and this is a point which should easily enough be cleared up. Whether there was an infecting case at any farm supplying the suspected milk will probably never be decided, but the fact that none was found must not be regarded as conclusive evidence against the theory of milk conveyance; failure to do so has been a common enough experience in milk-borne epidemics of all the infectious diseases. On the general question of probability it should be noted that the frequency of reputed instances of milk-borne poliomyelitis is not of a lower order than that in the commoner zymotics when allowance is made for their much greater prevalence. To sum up, we should say that Dr. AYCOCK appears to dismiss the evidence of person-to-person infection rather lightly, but has justice been done to the evidence of transmission by milk? It may be presumed that the facts with which he was dealing were equally known to, and probably in the first instance ascertained by, the public health officials who made the inquiry and who did not come to the same conclusion.

Annotations.

"Ne quid nimis."

THE WORLD INCIDENCE OF DISEASE.

MEDICINE and hygiene were alive to the advantages of international coöperation long before the League of Nations came into existence, but the Health Section is doing a great work in promoting a wider view of disease and in focusing the varied activities of different countries. Pathogenic bacteria have no nationalities, and, with the world rapidly shrivelling as far as human intercourse is concerned, epidemic disease is no longer a parochial question. The Health Section receives information on the prevalence of notifiable diseases from practically all countries where such information is collected; it distributes the collected facts by weekly and monthly publication, and issues every year a general survey, the fourth of which (for 1926) has recently been received.[1] The first part reviews the main epidemic diseases, and compares their present prevalence with their past history with many maps and diagrams. Plague deaths in India fell below 50,000 for the first time since it reached Bombay in 1898, and the trend in recent years hopefully suggests that the pestilence is now really on the decline, perhaps because vaccination is received more gratefully and abundantly, possibly because man is breeding out a more resistant race. The article on small-pox gives a summary view of the curious varieties into which the condition seems to be separating out; if the case mortality in England had been what it was in India there would have been 2427 deaths instead of 18, and perhaps fewer conscientious objectors. An interesting map shows the progress of a very severe type of relapsing fever, due to the European spirochæte, across Africa from the Niger in 1921 to the Sudan in 1926. It would be interesting to know why the case mortality of typhoid in Norway and Austria is less than half what it is in England and Japan. Nashville, the most typhoid-ridden big town in the United States, will welcome the new medical school which has been established there. And in this way under each of the important diseases the report gives much information and raises many questions. The second half of the volume is taken up with a mass of statistics arranged under countries. These are doubtless of uneven value; some of them are first rate, and even the worst are better than none. And we anticipate that their incorporation and publication will do a good deal to stimulate the countries with imperfect registrations to raise their standard to the best. The international bands of sanitarians who wander through one another's countries nowadays to see how things are done will help this on very much.

DOMESTIC HEATING.

THE need for preventing the pollution of the air of our cities by smoke has been brought prominently before Londoners by the dangers and discomforts of the ground fogs of Oct. 3rd to 7th and Nov. 7th to 10th, and the pitch-darkness of Nov. 23rd. While many parts of the Home Counties were bathed in sunshine the metropolis was shrouded in gloom, and vehicular traffic rendered slow and difficult. It is true that in the London area the deposit from the air diminished from 450 tons per square mile in 1915–16 to 284 in 1921–22, but since the latter date there has been little improvement, and we still have far to go before our air is clean. The percentage of sulphates in this deposit, which amounted in 1915–16 to 17, fell to 8 in 1921–22, showing a greater reduction in sulphur than in total deposit. It is estimated that in London domestic smoke forms about two-thirds of the whole, so that a smokeless solid fuel would

[1] League of Nations Fourth Epidemiological Report of the Health Section for the year 1926. London: Constable and Co.

go some way to purify the air. In a paper which he read at the recent Public Works, Roads and Transport Congress Mr. F. W. Goodenough drew attention to the contribution which the gas industry is making to the abatement of the smoke nuisance, setting out the case for gas and coke without being unduly sanguine as to the part which will be played by low temperature coke. Large scale experiments are now being made by the gas industry in coöperation with the Government in order to produce a fuel of this kind. At present some 65,000,000 tons of coal are burned yearly in the factories of the Kingdom, and 40,000,000 tons in domestic fires, while gas-works in carbonising another 20,000,000 tons produce about 10,000,000 tons of coke. This quantity of coke would not supply our domestic needs for, as Mr. Goodenough points out, the whole output may soon be absorbed by the increasing use of coke boilers. In order to produce enough low temperature coke to satisfy domestic requirements at least 50,000,000 tons of coal per year would be needed. Each ton would produce at the same time about 3500 cubic feet of rich gas having a calorific value of 800 to 1000 units, quite apart from other valuable by-products. A profitable outlet for these would have to be found. The 5,000,000 tons of anthracite mined per year in this country are palpably insufficient to solve the smoke problem; and the present type of slow combustion stove in which it is burned does not provide the ventilation which is one of the essential functions of a domestic fire. Electricity is hardly in the running for domestic heating in a country which has no great waterfalls or other supplies of cheap natural energy. To generate electricity by burning coal implies an initial heat loss of about 80 per cent., while the loss in producing gas and coke is of the order of 25 per cent. Thus when heat is required it is obviously uneconomical of fuel to obtain it by electricity. What, then, is the solution of the domestic smoke problem? It would seem unlikely that low temperature, or any form of coke, can be the way out, if only because the making of coke implies also making gas. The combination of gas with some form of coke for domestic cooking and heating appears, then, to give most promise of success.

INSULIN AND TUBERCULOSIS.

IT is generally recognised that the introduction of insulin has offered a new hope to the diabetic patient who at the same time suffers from active tuberculosis, and it was inevitable, therefore, that insulin treatment should, sooner or later, be tried for the non-diabetic phthisic. The few records so far published have shown varying results, some favourable and others unfavourable, especially as regards temperature reactions. Dr. J. Morin and Dr. F. Bouessée, of Leysin, have recently recorded a series [1] of favourable results with this group of non-diabetic phthisics. The injections of insulin were given subcutaneously half an hour before the meal. For the first two days 5 units were given, then two injections of 5 units were administered for two days, and afterwards the quantity was increased until 30 units were given in two doses daily. The duration of the treatment was about one month. Occasionally the limit of 30 units in a day was passed, but as a general rule this was regarded as a suitable maximum. No serious effects from hyperglycæmia were observed; transient disturbance three or four hours after an injection reacted immediately to the ingestion of carbohydrates. No local reactions of importance were noted, and there were no urticarial eruptions such as have been recorded by some observers. Furthermore, the patients, who were all afebrile at the beginning of the treatment, developed no rises of temperature as a result of the injections. In most of the cases appetite improved and the weight markedly increased, as is well shown by the charts accompanying the report. Cases in which the urinary excretion was measured showed no marked alteration and no œdema of tissues was observed. Eight cases in all are recorded, and Dr. Morin and Dr. Bouessée are satisfied from these preliminary tests that no harm results but that weight may be increased and some patients permanently benefited. It would be helpful to study a series of cases with metabolic tests carefully controlling the treatment at all stages.

[1] Annales de Médecine, October, 1927.

OPTIC NEURITIS.

Two different abnormal states of the optic disc have in the past been known as optic neuritis. One of them is a swelling which is often very marked and can be more or less accurately measured by the ophthalmoscope in terms of dioptres; it completely obliterates the margin of the disc and the veins are very much swollen. This condition may exist without any loss of visual acuity and is not really an inflammation of the nerve at all but an œdema caused by a pathological increase of intracranial pressure. The sign exists in both eyes, though it may be more advanced in one than the other. It is always of grave import, being one of the typical signs of intracranial tumour. So far as sight is concerned the condition, if unrelieved, passes sooner or later into optic atrophy, involving blindness, partial or complete. If, however, the intracranial pressure is relieved by a timely trephining operation the swelling of the disc in a typical case subsides and optic atrophy is averted. This important fact will always be associated with the pioneer work of the late Sir Victor Horsley. Since there is no inflammation of the nerve in these cases, the term "optic neuritis" has been considered inappropriate and the terms "choked disc" or "papillœdema" are now generally employed. True cases of optic neuritis are those in which there is actual inflammation of the optic nerve spreading either from the sheath or from an infective focus in the substance of the nerve. Toxins circulating in the blood due to general disease or to syphilis appear to be the most usual cause. In these cases the ophthalmoscopic picture is much less striking than in cases of choked disc. On the other hand, the loss of visual acuity occurs much earlier. The obliteration of the disc margin is the earliest and the most valuable ophthalmoscopic sign. The swelling of the disc and engorgement of the veins may be slight. When a toxin is the cause the condition is usually bilateral. When there is a localised inflammatory focus one eye only may be affected. Sometimes the retina is involved, as in albuminuric retinitis, and the case is one of "neuroretinitis." In other patients, where the focus of inflammation is some way behind the disc, the disc itself may appear normal and the case is said to be one of "retro-ocular" or "retrobulbar" neuritis. Since it is the macular fibres which are chiefly affected, the typical symptom of retro-ocular neuritis is a central scotoma. It is still uncertain whether ordinary tobacco amblyopia is a true retro-ocular neuritis affecting both nerves or whether the primary lesion is in the ganglion cells of the retinæ with secondary changes in the nerves. It is certain that one of the most common causes of retrobulbar neuritis is disseminated sclerosis. The causation of a great many cases remains a mystery, and although it has been usual to suspect infection from one of the nasal sinuses, especially since Onodi published his work demonstrating the thinness of the partition separating the optic nerve from the sphenoidal and ethmoidal sinuses, the actual number of cases where this causation may be considered to have been proved is relatively very small. The fact is that acute retrobulbar neuritis generally tends to get well in a few weeks without any treatment at all, and credit for the recovery is easily misplaced. This applies even to cases which are caused by disseminated sclerosis, although here the retro-ocular neuritis should be regarded as a danger-signal for what is in store in future. What has already been stated is common knowledge to the physician and ophthalmic surgeon. How far does it require modifi-

cation in the light of recent research? First, as to nomenclature. Though increased intracranial pressure is the most common, it appears to be not the sole cause of choked disc, and in order to have a name applicable to those cases alone which are due to increased pressure, Dr. H. M. Traquair, of Edinburgh, has suggested the term "plerocephalic œdema." We are inclined to agree with Sir John Parsons who, at the Edinburgh meeting of the British Medical Association,[1] as one largely responsible for the introduction of the term "papillœdema," deprecated the further complication of nomenclature proposed. Speaking at the same meeting, Dr. H. Ronne, of Copenhagen, stated that in his opinion it is impossible to draw a hard-and-fast line between papillary œdema and papillary inflammation. We must be satisfied, he says, in restricting ourselves to the knowledge that the high grades of papillary œdema are most frequently caused by increased intracranial pressure. He further called attention to a peculiar condition which is called choked disc with sudden initial blindness. This, he says, may be the consequence of disease in the trunk of the optic nerve and therefore without analogy with the choked disc of cerebral tumour. In such cases a wrong diagnosis has often been made. To avoid it a careful examination of the visual fields is of special importance. Similarly, no hard-and-fast line can be drawn between cases of true optic neuritis with visible changes at the disc and those of retrobulbar neuritis when the ophthalmoscopic appearance of the disc is normal. With regard to the connexion between this disease and the nasal sinuses, Dr. J. V. Paterson, after remarking on the tendency to spontaneous cure, went on: "I do not know any kind of cases in the whole range of medicine where one is more likely to be deceived with regard to the efficacy of operative measures than these cases of acute retrobulbar neuritis in young adults." Speaking at the same meeting, Dr. A. J. Ballantyne said: "Very few of my cases of retrobulbar neuritis, whether acute or chronic, have shown evidence of nasal sinus disease, and in the absence of clinical signs operation has not been recommended." Dr. de Schweinitz, on the other hand, was convinced that infective spheno-ethmoidal disease was a definite ætiological factor in many cases of retro-ocular neuritis. Onodi himself found nine cases of optic neuritis definitely resulting from nasal sinus suppuration, but in these cases the disease was extensive and destructive.[2]

SCARLATINAL INFECTION.

RETURN cases of scarlet fever have always been a bugbear to those who have had to manage isolation hospitals. It is usual to define as a "return" case an attack of scarlet fever which occurs in a family within 28 days of the return home from hospital of a recovered scarlet fever patient. The definition is, of course, quite arbitrary as the so-called return case may be a secondary case which has arisen in the family from quite another source of infection. In the past more or less elaborate systems have been devised, by means of discharging blocks with bathrooms and subsequent detention in a ward free from infection, to reduce the number of return cases to a minimum. Desquamation is now regarded as of no consequence. Complete absence of nasal or aural discharge has always been considered important. More recently, with the assistance of surgeons, attention has been given to the removal of diseased tonsils and adenoids prior to discharge from hospital.

With all these precautions, however, cases continue to occur where the patient leaving hospital appears to act as an infector of others. In the Hull report for 1926 Dr. W. Allen Daley describes the experiences of a family consisting of the parents, three girls, and three boys. Two of the sisters, age 15 and 3 respectively, were admitted to hospital f scarlet fever, one on the second day of the illnes and the other, desquamating, on the thirteenth da of the illness. Both illnesses ran a normal cours and the two sisters were discharged after 32 days hospital. Five days after their return home t third sister, aged 9, developed scarlet fever. S was removed to hospital at once and remained the 29 days. Twenty-four days after her return hom a brother, aged 6, contracted scarlet fever. He w nursed at home, while his two brothers were sent stay with relations. This illness ran a normal cour and in due time the house was disinfected and l two brothers returned home. Twenty-seven da after disinfection a brother, aged 13, develop scarlet fever, went to hospital, remained there 35 da and returned home. The remaining child, a bo aged 11, succumbed to the disease 16 days after t return home of the second brother, and was taken hospital. Why did not these susceptible childr take the disease from the first two cases, instead having it in serial numbers over a period of abo 250 days? All the six illnesses ran an uncomplicat course and there were no discharging noses or e to make the spread of infection likely. All expe enced medical officers of health can cite somewh similar occurrences, and it seems probable th immunity from scarlet fever must vary from time time in a more capricious way than immunity diphtheria as shown by the Schick test. Possibl those who have had experience of the Dick test m have come across evidence of day-to-day variati in scarlet fever immunity.

The same apparently capricious behaviour of scarlet fever infection is observed in its relation milk. On the one hand, we have cases occurring the families of dairy farmers and dairymen, frequen in circumstances which would seem to make tra mission of the infection to the milk a certainty. nothing happens. On the other hand, when a mi borne epidemic actually does occur, it is, as often as n extremely difficult to explain how or why the m became infected. Milk, when infected, is a very pot medium for transmitting the infection back to hun beings. As proof thereof it has been noted that milk-borne epidemics the incubation period is shorte and persons, immunised by a first attack, frequen contract second or abortive attacks with pronoun throat symptoms. Are these phenomena to explained by the increase of dose caused by growth of the virus in the milk, or by the fact t the irrigation of the tonsils and throat with infec milk is a peculiarly effective method of inoculatio Until we know more about the causal mic organism we are confronted by several unkno quantities—the amount of the dose, the variability the immunity, and the existence of carriers.

TREATMENT OF RICKETS IN MONKEYS.

IT has long been known that monkeys in captiv in the temperate regions suffer from rickets and variably susceptible according to age and spec Some succumb in a space of months, others survive years; but even the latter scarcely ever breed still more rarely (perhaps never) rear their you Efforts to combat the disease by dietetic means h not proved very satisfactory owing to the disincli tion which monkeys have for consuming fats o sufficient scale. Recent work by E. M. Hume H. Henderson Smith[1] shows that when a mon kept under ordinary menagerie conditions has de loped severe rickets, easily demonstrable by ra graphy, it can be cured by daily exposures, last 10–20 minutes, to a mercury-vapour quartz la The same workers, together with N. S. Lucas,[2] h also shown that the mercury-vapour quartz lamp

[1] Reported in THE LANCET Sept. 17th, p. 601. For original papers by Paterson, Ronne, and Ballantyne see Brit. Med. Jour., Nov. 12th.

e used prophylactically to keep marmosets in health nd fine breeding condition. These little creatures are ighly susceptible to rickets, and though there are a ew scattered records of young being born in this ountry, they do not seem ever to have survived. nder the influence of the mercury-vapour quartz mp, however, young have been born at the Lister nstitute and have thriven. The possibility of breeding onkeys in captivity offers new opportunities to orkers in psychological laboratories, doing the type work, for instance, which has been done by Prof. . M. Yerkes at Yale. A knowledge of the means to ep them in health is of importance to all laboratory orkers who use monkeys, as well as to those who are charge of menageries and to those who keep monkeys pets.

THE ACTION OF LIPIODOL.

IODISED oil, in one form or another, has now come a valuable instrument in the technique of diological examination of the lung. Whilst firmly nvinced of its great value as a diagnostic procedure, . E. Archibald (Montreal) and Dr. A. Lincoln own (San Francisco) have recently published [1] a eful review of the subject, in which they call attenn to the possible dangers of its use when introced into the tracheo-bronchial system. They have ncentrated their attention chiefly on the particular paration sold under the registered name lipiodol, ich is an iodised vegetable oil containing 40 per t. of iodine. After injection into the tracheonchial system a large percentage of the oil is minated by expectoration or swallowing; this the hors consider of no interest. A proportion of the is, however, absorbed, and in certain cases has n found to cause symptoms of iodism. Most of se cases appear to have shown only mild symptoms iodism, but a few more serious complications have sen. In experiments on cats the authors found oil present in a minute state of subdivision in ny of the tissue elements that make up the pulnary structure—even in the cartilage of the smaller nchi. These facts were demonstrated by the use Scharlach R. in sections. The authors believe that absorption—which may be in some way assoed with an internal digestive power possessed by lung—is likely to be delayed in an extensively ased lung, especially if cavities are present, and y even so fill alveoli as to interfere with oxygen orption. Much apparently depends on the iodine rance of the patient, which, fortunately, in most viduals is high. The authors state, on the authoof Forestier, that after an intratracheal injection 0 c.cm. of lipiodol, the daily elimination of the ne during the first two weeks is 0·02 g. They e noted cases in which the lipiodol shadow showed ne radiogram for 15 months, though in the majority ases the shadows only persist for a few weeks. h regard to the technique of administration, the s of local sepsis, a false passage and laryngeal ma are discussed, and the suggestion is made that the first injection, at least, the bronchoscopic hod should be used, in order to obtain a satisory and direct visual examination of the injected . The effect of the cough reflex in disseminating oil into distant parts of the lung is also emphasised. gh reflexes have not been noted in ramifications ronchi smaller than those of the second order. has been stated that, inasmuch as the normal heo-bronchial tree can hold 5000 c.cm. of air, .cm. of injected lipiodol can be regarded as a l amount, but it must be remembered that in se this tracheo-bronchial capacity may be nished by as much as 50 per cent. Moreover, lipiodol is known to float on the top of sputum, locking of a small bronchus may occur, especially oints where the cough reflex is not excited.

s to the therapeutic effect of lipiodol on the rculous process the authors are in doubt, but ider that in certain cases and in properly regulated doses lipiodol may have a similar effect to that of tuberculin. Recent work on this subject by F. G. Chandler and S. R. Gloyne [2] would seem to show that the actual bactericidal effect of lipiodol on *B. tuberculosis* in vitro is not very great, and that there is no lipolytic action when this substance is injected into the pleural sac of normal rabbits, and no toxic effects on distant tissues. These workers suggest, in fact, that from a purely therapeutic point of view the effect of lipiodol is probably mechanical. In summarising the dangers which may result from the injection of lipiodol, Archibald and Brown record a small number of unfavourable cases which they have collected from the literature, including one case where subacute sepsis was considered to be due to lipiodol injection five days previously. Without any desire to minimise the undoubted value of lipiodol as a diagnostic aid in pulmonary disease, these authors believe that there are definite potential risks which should be weighed before patients are subjected to its indiscriminate use. Probably in the hands of skilled operators these risks are not great, but the method is obviously one which cannot be carried out without proper safeguards and training in acquiring the technique. In a later communication [3] the same authors give the results of an experimental investigation with lipiodol. They injected cats intratracheally, and found that cough alone increased the rapidity and degree of penetration of lipiodol and lipiodol-sputum emulsion, and that this action was still more definitely marked with tracheal compression. In fact, an actual in-driving effect on the lipiodol was caused by cough. No similar indriving effect was observed with thick, tenacious sputum. Apparently, whereas coughs may tend to drive a fluid substance, such as lipiodol or lipiodol-sputum emulsion, further down the bronchial tree, it has not the same effect in breaking up and forcing thick, tenacious sputum into the finer ramifications.

MEDICAL AMERICANA.

AN Exhibition of Early and Later Medical Americana was held in the library of the New York Academy of Medicine, when the new building of that institution was opened last month. The Catalogue contains 95 items, all of which are of interest to students of the history of disease whether they be Americans or no. The first medical publication in the United States, of which a photostatic reproduction is shown, was a broadside printed at Boston in 1677, entitled "A Brief Rule to Guide the Common-People of New England how to order themselves and theirs in the Small Pocks, or Measles." The author was Thomas Thacher, pastor of the Old South Church, in Boston, who had picked up a smattering of medicine sufficient in his day for the needs of his flock. He gives sensible directions for the treatment of the sick, but is, of course, ignorant of inoculation. It was not till 1721 that Benjamin Colman, also a preacher, published at Boston "Some Observations on the New Method of receiving the Small-Pox by Ingrafting or Inoculating," a method of which he was the advocate. Lady Mary Wortley Montagu had only recently described inoculation as practised in Constantinople. In 1721, probably after Colman's publication had appeared, Increase Mather, at one time President of Harvard, republished "Some further Account from London of the Small-Pox Inoculated." The title of the second edition of his pamphlet, reproduced in the Catalogue, refers to a "late Scandalous Pamphlet entituled Inoculation of the Small Pox as practis'd in Boston, &c.," and we are left in doubt as to what attitude the father took towards the innovation of his son, Cotton Mather, who had brought the knowledge of the treatment to New England, where it had been at once acted upon by Zabdiel Boylston. On June 26th, 1721, Boylston inoculated his six-year-old boy, and thus began a controversy which raged for many years in America,

many pious Puritans and witch-burners holding that the practice was contrary to the will of God, just as, at a later date, their pietistical successors opposed anæsthesia. Vaccination was another much-canvassed method, and, as several book-titles show, cow-pox figured in America as kine-pox. Benjamin Waterhouse's work on "A Prospect of Exterminating the Small-Pox," in two parts, is exhibited, the first part having appeared at Boston as early as the year 1800.

Of American medical journals the first was the *Medical Repository*, which ran into 23 volumes from 1797–1824. The earliest one in Canada, the *Journal de Médecine de Quebec*, was first published as a quarterly in January, 1826, but met its end in little more than a year. The hospital reports came from the Hôtel Dieu, the oldest Canadian hospital, founded in 1639. Benjamin Franklin's letter on catheters and letters to Pringle and George Wheatley are on exhibition, the first-named being the original autograph presented to the Academy by Fessenden Nott Otis. "Medicine owes a great deal to this remarkable man," says the Catalogue, for though Franklin was not a doctor he was elected to several medical societies. He wrote amusing trifles for his friends, and a facsimile is shown of his "Dialogue entre le Goutte et M. F. à Minuit le 22 Octobre, 1780." William Beaumont, though an English F.R.C.S., was American born and his classic work on the digestion was published at Plattsburgh in 1833 under the title "Experiments and Observations on the Gastric Juice and the Physiology of Digestion." This was the record of his experiments on the famous Alexis St. Martin, who had a fistula of the stomach through which Beaumont was able to observe the movements of the gastric juice. The work here shown is the property of the Academy. Oliver Wendell Holmes, the poet and wit, made one great contribution to medicine when in 1843 he read his paper on the Contagiousness of Puerperal Fever before the Boston Society for Medical Improvement. The famous paper appears as Art. V. in the *New England Quarterly Journal of Medicine and Surgery*, which lasted for about a year in 1842–43. Next to it we note Ephraim McDowell's "Three Cases of Extirpation of Diseased Ovaria." This appeared in the *Eclectic Repertory* in 1847, but the first operation was performed in 1809. The pioneer writings on Anæsthesia by Crawford Long, Bigelow, and Morton will receive close attention. We cannot write here in detail of the more recent works or articles by pioneer medical men, and it must suffice to mention such names as Halsted, Corning, Marion Sims, Austin Flint, Stough Bobbs, Huntington, and Weir Mitchell. All these are represented in an exhibition whose promoters, including the Committee on Exhibits and the learned librarian, Dr. Archibald Muloch, deserve the heartiest congratulations on their achievement.

A CONFERENCE ON ACTINOTHERAPY.

AN international exhibition and conference, organised by the *British Journal of Actinotherapy*, is to be held at the Central Hall, Westminster, from Tuesday to Friday, Dec. 13th to 16th. The conference is divided into three sections, the first of which (Tues. and Wed.) will discuss light and heat in medicine and surgery; the second (Thurs.), scientific research in relation to actinotherapy; and the third (Fri.), recent advances in optics. Each section will be opened by papers from distinguished workers at home or abroad, to be followed by general discussion. At the first section, which touches medical practice most closely, Sir Henry Gauvain will preside, and papers will be read by Dr. Franz Nagelschmidt (Berlin), Dr. L. G. Dufestel and Dr. Jean Saidman (Paris), Dr. A. Eidinow, Dr. F. Hernaman-Johnson, and Dr. E. P. Cumberbatch (London). On the Wednesday evening Dr. H. Stanley Banks will give an address on the place of actinotherapy in public health work. At the second section, Prof. E. C. C. Baly will preside and papers will be read by Dr. Leonard Hill, Mr. I. M. Heilbron, D.Sc., and Dr. F. H. Humphris. The exhibition, to be held concurrently with the conference, will be opened on Tuesday at 2.30 P.M. Sir Alfred Mond; apparatus and accessories of kinds for ultra-violet and kindred therapy will the be shown, some for the first time. Demonstratio will be given, amongst them one by the staff Westfield College, London, on the effect of ult violet radiation on plants. A concession for reduc rates on the railways has been obtained. Invitati tickets may be obtained from the office of the Journ at 17, Featherstone Buildings, London, W.C. 1.

PHYSIOLOGY AT THE ROYAL SOCIETY.

IN his opening address at the anniversary meeti of the Royal Society on Nov. 30th, the Preside Sir Ernest Rutherford, spoke of contributions ma to science by physiologists living and deceas In the person of Ernest H. Starling the Society h lost a stalwart champion of the claims of research, a one who had found in physiology the central inter and enthusiasm of his life. Starling's aim had be as he himself put it, "to attain to a comprehensio the wisdom of the body and the understanding the heart and thereby to the mastery of disease a pain." Most famous of his joint researches wh Bayliss was the work on the stimulation of pancrea secretion following the discharge of stomach conte into the small intestine, which led to the discov of secretin and the conception of chemical messeng or hormones. Turning to living physiologists, E. Rutherford spoke of the award of the Cop Medal to Sir Charles Sherrington, whose wo embodied in some 200 original memoirs, had revea a fundamental plan and orderly sequence in the re actions of the body. He had also given impu to the original and far-reaching investigations the late Rudolf Magnus, of Utrecht, on animal post Sherrington's work, having provided the clue to understanding of many of the motor symptoms nervous disease, held out promise that even higher functions of the central nervous system wo not remain permanently beyond the reach of m experimental inquiry. Sir Thomas Lewis, to wh a Royal Medal had been awarded, had taken a lead part in the remarkable growth of our knowledge the mammalian heart-beat. Until he began his w nothing was known for certain as to the relatio anatomical structure in the heart to the origin propagation of the beat. In this special field physiology and pathology Lewis's researches replaced scattered observations by coherent established theory. The President also alluded to award of the Buchanan Medal to Dr. Major Greenwo whom he described as almost unique in the posses of both the medical knowledge and mathemat ability essential to the elucidation of many probl in physiology and epidemiology.

THE CONWAY EVANS PRIZE.

The first award of the Conway Evans prize has b made to Sir Charles Sherrington. It may be reca that when in 1925 the residuary trust funds of estate of the late Dr. Conway Evans, medical of for the Strand district, who died in 1892, were tr ferred to the President of the Royal Society and President of the Royal College of Physicians of Lon and their successors in office, the terms of the bequ directed them to apply the proceeds "in giv rewards to such person or persons who in the opi of the Presidents have rendered or shall from tim time render some valuable contribution or addi to science as it exists at the time of my death ei by invention, discovery, or otherwise." In accorda with this direction the Presidents have awar 500 guineas to Sir Charles Sherrington on the gro that his work on the physiology of the nervous syst and chiefly on the physiology of the brain and sp cord of the higher animals, has brought many com nervous functions for the first time within the rang investigation and analysis. His discoveries, they have had a profound influence throughout the w

on the experimental sciences of physiology and psychology, and have thrown a flood of new light on many of the symptoms of nervous disease.

Dr. Sydney Smith, principal medico-legal expert to the Egyptian Government, and professor of forensic medicine in the School of Medicine at Cairo, has been elected to the chair of forensic medicine in the University of Edinburgh, left vacant by the death of Prof. Harvey Littlejohn.

THE next social evening of the Royal Society of Medicine will be held on Wednesday, Dec. 14th, when Sir James Berry (the President) and Lady Berry will receive the guests at 8.30 P.M. in the Society's House at 1, Wimpole-street, W. At 9.30 Sir Alexander Houston will give an address entitled the Romance of London's Water-supply, and this will be followed by demonstrations.

IT has been the practice of the Royal Medical Benevolent Fund for many years to present to the annuitants and some of the most necessitous grantees a Christmas gift of 25*s*. The treasurer now makes an appeal for £370 to keep up this practice. The Committee has not in hand any special fund to draw upon to meet this Christmas gift, to which the recipients in former years are no doubt looking forward, and we hope that many of our readers may be able to send subscriptions to Sir Charters Symonds, at the offices of the Fund, 11, Chandos-street, Cavendish-square, London, W. 1.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. L. S. Goss to be Surg. Comdr.

Surg. Lt. (D) F. R. P. Williams to be Surg. Lt.-Comdr. (D), F. W. Besley and J. W. Simpson to be Surg. Lts.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. (D) D. MacGregor to be Surg. Lt.-Comdr. (D).

ROYAL ARMY MEDICAL CORPS.

Temp. Col. (Bt. Col. and Lt.-Col.) J. W. West, K.H.S., relinquishes the rank of Temp. Col. on ceasing to be empld. as Consulting Surg. to the British Army.

Maj. L. A. A. Andrews is placed on the half-pay list on account of ill-health.

Maj. P. M. J. Brett is re-empld. under Art. 507 (*b*), Royal Warrant for Pay and Promotion, 1926.

S. R. M. Mackay to be Lt. on prob.

ARMY DENTAL CORPS.

Lt. R. G. Law to be Capt.

TERRITORIAL ARMY.

Hygiene Companies.—Capt. W. D. Quirke, having attained the age limit, relinquishes his commn.

ROYAL AIR FORCE.

Flying Officer J. McCarren resigns his short service commission.

UNIVERSITY OF LONDON MEDICAL GRADUATES SOCIETY.—At a dinner held at the Langham Hotel on Nov. 25th it was decided to form a Society of Medical Graduates of the University of London. Sir StClair Thomson presided and the formation of the society was proposed by Sir John Rose Bradford, President of the Royal College of Physicians of London, and seconded by Sir Cuthbert Wallace, Dean of the Faculty of Medicine of the University. A provisional committee will formulate a constitution to lay before a general meeting of the society early in 1928. Mr. W. Adam Eccles was elected acting hon. treasurer, and Dr. C. A. H. Franklin and Dr. Dorothy Hare acting hon. secretaries. Medical graduates of the University may join the society by writing to the hon. secretaries at 124, Harley-street, W. 1.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLII.

THE PREVENTIVE TREATMENT OF DISABILITY AFTER FRACTURES.

To attain success in the treatment of a fracture it is necessary first of all to have a clear idea of what we are setting out to do. The old aim of treatment—merely to produce strong bony union in good line—has caused incalculable pain and loss of wage-earning capacity, and the ideal towards which we should strive nowadays is something altogether wider—namely, restoration of the patient to the state of bodily and mental efficiency in which he was before the accident. Not only the injured bone, but the muscles, joints, and circulation, the dexterity, and even the mental outlook, have all to be brought back to normal.

Accurate diagnosis is the first step towards efficient treatment. Whenever possible in any case of fracture or probable fracture, two radiograms should be taken, in planes at right angles to one another. Where this is anatomically impossible, much may be learned from stereoscopic radiograms. It is not enough to know that a bone is broken; it is necessary to know exactly how it is broken. In many cases it is only by means of X rays that the fact of fracture can be established. And it must be remembered that a small lesion does not necessarily connote a small disability; for example, a fracture of the carpal scaphoid (which is very commonly overlooked), or a chip-fracture of a finger, may be very disabling.

Splints.

Having established the fact of fracture, the next step is *not* to choose a splint. On discovering the fracture the thought should not be, "What splint shall I use?" but rather, "Need I use a splint at all?" A splint is only required when an equally good functional result cannot be attained without it, and if in every case the mechanics of the fracture are carefully considered from this point of view, it will be apparent that splints are often put on when they are quite superfluous and even harmful. A cumbrous back-splint and foot-piece, for example, cannot influence the position of a broken middle metatarsal; the adjacent bones splint it, rest can be secured by slinging the foot, and other support only induces unnecessary stiffness of joints and wasting of muscles. A fracture of the lowermost end of the fibula, again, cannot possibly become displaced; it is too firmly held by its ligaments. Here a splint is not merely unnecessary but actually does damage.

It should always be remembered that, apart from traction-splints, no splint should ever be used to produce reduction; it serves only to maintain it. For instance, if the bones of a child's forearm are bowed, it is useless to try to push them straight by the pressure of a projecting pad on a splint; the bandages will cause a splint-sore if they are tight enough to correct the deformity. The limb should first be "set" properly, and then kept in place by the splints. It is well to remember, too, that wooden splints, being made to fit everybody, really fit nobody; they do not fix a limb, but only rest it. Often, it is true, that is all that is needed, but sometimes true fixation is required, for after fracture the muscles are in a highly irritable state and pull upon the fragments with much more than their normal power. Whether or not this will displace the fragments depends mainly on the type of fracture and the direction of the muscular pull. The risk is small where the fracture is transverse and the muscles run axially, whereas it is large when the fracture is oblique, or where the muscles pull obliquely on the fragments. When true immobilisation by splints is desired, it is usually a

good plan to use plaster-of-Paris, carried well beyond the origins and insertions of the muscles which are acting on the fragments.

Reduction.

If reduction presents the least difficulty, full anæsthesia should be employed. The abolition of pain and of muscular resistance more than compensates for the patient's aversion to being made unconscious, and for the additional trouble and expense. In particular, every case of Colles's and Pott's fracture should be reduced under general anæsthesia, for which purpose gas is inadequate, unless the surgeon and anæsthetist are both exceptionally skilful.

All fractures should be reduced at the earliest possible moment, before effusion and increasing spasm have made the conditions harder. It is wrong to wait until the swelling is going down, for by that time contracture has appeared, and both reduction and retention have become unnecessarily difficult. A good primary reduction, moreover, always gives a better result than any secondary reduction. This applies to operative as well as non-operative treatment. If it is thought that a fracture should be treated by operation, the surgeon should be called in at the earliest possible moment, that he may have the opportunity of early reduction if he thinks proper. Anyone who has striven with an old fracture with shortening will appreciate this point.

Before undertaking reduction it is important to detect any injury of nerves, on which a charge of unskilful treatment is often based. Involvement of the musculospiral nerve in fracture of the shaft of the humerus, and of the circumflex in injuries of the neck of the bone, are cases in point. The former calls for hyperextension of the wrist, in splints, and the latter for abduction of the upper limb to a right angle.

Reduction should always be as complete as possible. Whilst bad alignment is sometimes compatible with good function it is nevertheless true in all cases that the better the alignment the better is the functional result. And it cannot be too strongly emphasised that in the case of the lower limb any deviation of the normal axes of the joints will inevitably result in serious and permanent disability. The leg differs from the arm in that it is a weight-bearing limb. To make it work with its joints "out of truth" is like driving a car with a bent axle, producing unequal strains. "Mechanical arthritis" appears—i.e., osteo-arthritis due to mechanical causes—and becomes steadily worse so long as the static fault remains. Shortening of the limb is of no great consequence if the bones remain parallel, as seen from the front. A slight lateral displacement of tibia and fibula is compatible with very good function provided that the upper and lower fragments remain parallel. But the moment that any abduction or adduction appears in any part of the lower limb, and the joint-surfaces are thrown "out of truth," disability is a certainty. Every such condition demands complete correction at the earliest possible moment. It is futile to hope for the least relief from massage, special boots, wedging the sole, osteotomies, and the like; none of these can correct faulty mechanics. Permanent crippling will always occur, in Pott's fracture, unless the limb be set with the axes of the knee-joint and of the ankle-joint absolutely transverse; the top of the astragalus must always be exactly parallel with the ground. Valgus is fatal.

Massage and Movements.

After-treatment begins as soon as reduction is completed. Massage can be used with advantage in most fractures from the very day of injury; it gets rid of effusion, allays muscular spasm, and so minimises pain. Skilled sedative massage often aids reduction. Later, massage is employed to prevent wasting, and all possible joints are exercised to full range. Especially with compound fractures is it important to maintain the movement of unaffected parts; with fractures of the leg the hip must b moved daily, and with fracture of the forearm a sti shoulder is a disgrace. It must always be remem bered that the functional utility of the limb as whole is the measure of success in treatment; th bone is sometimes only a minor consideration. Wit fractures near joints, for example, it is usually mo important to consider the function of the joint tha the state of the bone; early movements are ind cated, and often it is possible to do without a spli and to move the parts from the first. A Colles fracture impacted in good position—i.e., witho backward rotation—is an example. Early mobilis tion is often facilitated by operation—e.g., wiring the patella, and direct fixation of supracondyl fractures.

This brings me to the question of movement Passive movements affect the joint-surfaces ar prevent adhesions, but do not affect the muscles the tendons in their sheaths. Active movements a always preferable, therefore, and in addition th stimulate the patient's mind, and compel him to tal an active interest in his cure. If there is ever ar doubt about the propriety of movements, or the sk of the masseuse, active movements should be pr ferred to passive, as they provide the added securi of pain. But passive movements are often necessa at first, because the freedom of the joints must restored before tired, wasted muscles can be expect to move the dead-weight of a limb.

Apprehension, often amounting to hysteria, pla a large part in many cases of fracture. Patients a often afraid to move their limbs, or confidently an cipate much greater disability than is really preser Here, again, prevention is better than cure. Patien should be encouraged, from the first, to move much of their limbs as possible, and to move the vigorously. In Colles's fracture, for instance, th should be made to clench their thumb and finge quickly and powerfully from the moment the fractu is first reduced. The medical profession itself responsible for much of the difficulty in the trea ment of fractures to-day. The public has be taught for years that their limbs must be kept absolute rest in splints for weeks, and they ha learned their lesson too well. Passive exercises a bad, because they do not call for physical and ment coöperation on the part of the patient. The whc atmosphere of treatment should be stimulative, a the result, as I have said, cannot be regarded satisfactory until not only the patient's injured lim but his whole capacity for daily life and work, ha been restored. At first mere range of moveme and muscular power have to be regained, but dexteri and fine coördination must later be cultivated ane and this can only be done by active, voluntar exercises. This may be very important to thc whose occupations are highly specialised.

Electrical Treatment.

Electricity is not a panacea in fracture-treatme It is useful, however, in stimulating the circulati and muscular contractions in the early stages f treatment when a limb is still in splints, and la on in reinforcing a nervous patient's feeble volunta efforts. It is not enough merely to touch the musc repeatedly with a faradic electrode without a effort on the part of the patient; the proper way to make him contract a muscle, and at the sa moment throw in a powerful faradic current so as bring the contraction up to maximum power. Keit work has shown that muscular contractions are f foremost importance in causing bony union. Faradi is also useful in convincing a hysterical patient th he can contract his muscles quite well, although thinks he cannot, and a really strong current cu many a malingerer.

GENERAL MEDICAL COUNCIL.

PENAL CASES.

TUESDAY, NOV. 22ND.

THE Council, in accordance with custom, heard the ases in public and deliberated on their findings in amera.

Reported by the Dental Board of the United Kingdom.

The Case of James Pickup, registered as of 124, tudley-terrace, Walmersley-road, Bury, in practice n July 22nd, 1878, L.D.S. R.C.S. Irel. 1888. This espondent had been convicted before magistrates for eing drunk and disorderly, for indecent behaviour, nd for importuning for immoral purposes, and the oard had recommended his erasure. Mr. Pickup did ot attend. His counsel, Mr. Maurice Healey, bjected that the kind of misdemeanour referred to Section 13 of the Dentists Act, 1878, was an indict-ble misdemeanour, and that consequently the ffences for which Mr. Pickup was convicted, not eing indictable misdemeanours, did not come within ie disciplinary jurisdiction of the Council. The resident stated that the Council had already been lvised, and had always acted upon the view, that ie word "misdemeanour" was used in the Act in s wider sense, and he accordingly overruled the bjection. The Council ordered Mr. Pickup's name be erased from the Register.

The Case of Frank Ernest Coe, registered as of), Defoe-road, Tooting, S.W. 17, Dentist, 1921, hose erasure the Dental Board had recommended r obtaining payment from a society for a denture hich he had not in fact made. The respondent, ho was not represented, pleaded that, since the atient had had several sound teeth left, he had ecided to fit a partial set, which took much longer an a full denture; owing to shortness of funds he ad claimed the amount at once. He had finished ie set in the same year. He had failed to appear efore the Dental Board on account of ill-health. he Council remitted his case back to the Board r further inquiry and report, and the President lvised him to be present at that hearing.

The Medical Register.

Cases adjourned from Nov. 24th, 1926:—

The Case of Percy Bateman, registered as of 423, ew Cross-road, S.E. 14, L.R.C.P. Edin. 1906, R.C.S. Edin. 1906, L.F.P.S. Glasg. 1906. This actitioner had been convicted of drunkenness on ur occasions between 1914 and 1926, and the Council d postponed judgment for six months. He was not esent. The Council, said the President, had had me difficulty in coming to the conclusion that the idence asked for at the original hearing had been lly supplied, and, in order to give Mr. Bateman e opportunity of supplying that evidence in satis-ctory amount and character, they adjourned the aring until the meeting of the Council in May, 28.

The Case of Thomas Blaney, registered as of 434, ondon-road, Norbury, S.W. 16, L.R.C.P. Edin. 1920, R.C.S. Edin. 1920, L.R.F.P.S. Glasg. 1920. Mr. aney had appeared before the Council at the last nter session for a conviction for drunkenness in 25, and for having been drunk when patients were der his care. The Council were satisfied with the idence of good conduct produced by the respondent, d did not direct the erasure of his name.

Cases adjourned from May 26th, 1927:—

The Case of Jogesh Chandra Bose, registered as 276, Chenywood-road, Birmingham, M.R.C.S., R.C.P. 1923, whom the Council had found guilty of giving a medical certificate which was untrue, misleading or improper, in a lax and careless manner. Mr. Oswald Hempson, on behalf of the respondent, read several letters from medical practitioners and others testifying to his good conduct during the past six months, and repeated his assurance that he would be extremely careful in future. The Council decided not to erase his name from the Register.

The Cases of (*a*) *Lawrence Crombie*, registered as of Dunollie, Dalmuir, Glasgow, M.B., Ch.B. 1913, U.Glasg.; (*b*) *Eliazer Gelfer*, registered as of 45, Abbotsford-place, Glasgow, C.5, L.R.C.P. Edin. 1923, L.R.C.S. Edin. 1923, L.R.F.P.S. Glasg. 1923; and (*c*) *William Mason Hamilton*, registered as of 63, Dixon-avenue, Crosshill, Glasgow, M.B., Ch.B. 1921, U.Glasg., whom the Council had found to have left unqualified assistants in charge of poisons. Dr. Hamilton brought evidence that he had closed the dispensary from which poison had been unlawfully sold. The solicitor for the Pharmaceutical Society, Mr. W. Quarrel, brought forward no further facts concerning this respondent, and the Council decided not to erase his name.

Concerning Dr. Crombie, however, Mr. Quarrel brought further evidence, that an inspector had seen a witness buy a tin of "Rankin's ointment for destroying vermin on the head," a scheduled poison, from the same assistant who had sold the lysol which was the subject of the original charge. In defence, Miss Jean Dougan, the assistant, testified that since Dr. Crombie's appearance before the Council in May, some of the poisons had been put under lock and key and the remainder removed to the shop of Mr. T. F. Armstrong, a chemist. She had been instructed to sell nothing containing poison. At that time no Rankin's ointment had been in stock, and she had only ordered two tins to be made up by Dr. Crombie's regular chemist in order to meet an inquiry for it made two days before the visit of the inspector. She had only told Dr. Crombie of her mistake after the sale, and he had promptly returned the other tin. She had thought she might sell the tin, labelled poison, because it was for external use. She was no longer employed by Dr. Crombie, and the shop now belonged to Mr. Armstrong. The witness who had bought the tin was not the person who had ordered it. Mr. Quarrel denied that the Society knew anything about the order. Mr. Armstrong, in evidence, confirmed that he had supervised the removal and segregation of poisons in May, and had advertised, on the instructions of respondent, for a qualified female assistant, but had had no suitable replies. He had asked his wholesale dealers to find him a qualified employee, with no more success. Miss Dougan had therefore been retained, and all possible precautions taken. Dr. Crombie had asked witness to take over the shop in May, but witness had temporised until the ending of his financial year. An agreement had been actually drawn up to transfer the shop on Oct. 1st, and, although this had not been signed, witness had been responsible from that date and had been taking the receipts. He had warned his assistant to send no poisons up to the dispensary, and the Rankin's ointment had been supplied by a mistake. This preparation was very seldom used. Cross-examined, he admitted that the assistant's salary had been paid by one of the medical partnership during October, but for his convenience.

Mr. O. Hempson read affidavits from the respondent's partner and the clerk to the local Insurance Committee that, but for the contract with the Committee, the firm would have given up the shop after the first complaint. As it was, the transfer to Mr. Armstrong had been completed before the sale of the ointment. Respondent gave evidence corroborating that of the other witnesses, and stated that he had, on the very day of the sale, asked Miss Dougan whether she was handling any poisons. He had not heard of the ointment until after the sale. If the actual buyer had been known to the girl, witness would have made every attempt to recover the box.

He had instructed Mr. Armstrong to supply no poisons direct to Miss Dougan. He had tried to make "a water-tight compartment, but it had leaked." Mr. Hempson read testimonials to the respondent's character and conduct, and outlined the comprehensive steps he had taken to prevent the sale of poisons in his shop. The Council decided not to erase Dr. Crombie's name from the Register.

On consideration of Mr. Gelfer's representations and evidence to character and conduct, the Council decided that his name also should remain on the Register.

WEDNESDAY, NOV. 23RD.

The Case of Cecil John Rhodes Morrison, registered as of Trumisgarry, Lochmaddy, North Uist, L.R.C.P. & S. Edin., 1925, L.R.F.P.S. Glasg., 1925. Respondent appeared before the Council on the following charge :—

That you were on Feb. 22nd, 1927, at the Sheriff Court, Edinburgh, convicted of the following offence—namely, of recklessly discharging three shots from a revolver loaded with ball cartridge and wounding two persons to the effusion of blood, and were sentenced to four month's imprisonment.

He was not represented by counsel. The Council's solicitor explained the facts. Respondent had become intoxicated celebrating the New Year with some friends, and when he returned home his brother-in-law had accused him of being drunk. Respondent had become angry, and after words and blows had been exchanged he had fetched a revolver and shot at random round the room, wounding his brother and sister-in-law and missing only his brother-in-law. After this, being confused, he had changed his clothes and walked off with his violin on tour. He had slept in the Pentland Hills and found himself in the morning 21 miles from Edinburgh. On returning to the house and hearing that the police were asking for him he had proceeded to the police-station and had been arrested. At an interview, at which the Council's solicitor had warned him that the Council, whatever they thought about the shooting, would think still more of the habit which had caused it, respondent had promised to abstain from alcohol in future. On hearing respondent express his contrition and good intentions the Council decided not to erase his name.

The Case of Vernon Raymond Joseph De Boissière, registered as of 5503, Wellington-street, Verdun, Montreal, M.R.C.S. Eng. 1923, L.R.C.P. Lond. 1923. This practitioner was summoned on the following charge :—

That, being a registered medical practitioner, you abused your position by committing adultery with Mrs. Annie Dee, a married woman, with whose family and household you stood in professional relationship, of which adultery you were found guilty by the decree of the Probate, Divorce and Admiralty Division (Divorce) of the High Court of Justice, dated Jan. 12th, 1927, and made absolute on July 25th, 1927, in the case of Dee *v.* Dee and De Boissière, in which you were the co-respondent.

And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The Council's solicitor obtained leave to amend the charge by the insertion of the following words after the first paragraph :—

And/or that being a registered medical practitioner, you abused your position by committing adultery with Annie Dee (a married woman) subsequent to the date of the service of the petition presented in the said divorce proceedings following and arising out of the friendship which you had formed with the said Annie Dee during the period of such professional relationship.

The Council's solicitor opened his case by reading extracts from the statutory declarations produced in evidence at the hearing before the High Court. Mr. Dee had there deposed that he had made Dr. De Boissière's acquaintance in March, 1926, and had called him in to attend his family professionally. From about May his wife's affection for him had begun to change, but he had had no reason for suspicion. On August 8th he had been sent for to the doctor's surgery, where Dr. De Boissière, his wife, and Mrs. Dee had been present. Mrs. De Boissière had stated that her husband had confessed to being in love with Mr Dee. Witness had suggested that it was an infatu tion, and the doctor had replied : "No, it has go further than that." Witness had never lived with h wife again and had filed a petition for divorce. T chief evidence on which the decree had been grant had been that of a girl relative, who had testified the compromising conduct of the parties ; th evidence, said the Council's solicitor, he rath discounted, as it contained details which it w unlikely that the witness could have observed. D De Boissière, in an affidavit, had denied adultery a had stated that Mrs. Dee was hysterical, had haunt him, and had constantly summoned him witho cause ; he had done his best to break off relatio with her. When the petition had been served up him he had, acting upon wrong judgment, given his practice and gone to Canada. Two days befo the boat sailed Mrs. Dee had booked her passage al and had travelled on it as well, but she had be prevented from landing by the immigration authoriti During her return voyage, added counsel, she h written to her husband expressing great distress a regret, and asking for a reconciliation.

Mrs. Annie Dee, in examination, stated that s was living with her mother. She had first met D De Boissière at Amiens in 1918, before he w qualified ; she had been in the W.A.A.C. They h not been particular friends. She had met Mr. D in the same place. She had lost sight of the doct until March, 1926, when she had taken a cousin consult him, and only remembered him after so minutes' conversation. Dr. De Boissière had sub quently attended witness's husband and son. Witn denied that she had attempted to commit suicide his surgery, but admitted that she had becom hysterical after her baby had been taken away fr her on August 9th, the day after she and her husba had parted and after the interview between t families in the surgery. She did not remember wh words exactly the doctor had used to Mr. Dee abo his relationship with her. She denied having ask Mrs. De Boissière to hand over her husband to h but said that Mrs. De Boissière had announced h intention to go back to her mother in the States, a advised her, witness, to go to Montreal with t doctor, and had offered to help her in settling the Mrs. De Boissière and her sister had been in t Canadian Pacific office at the same time as witn and the doctor when he booked his berth, and he h also booked one for witness ; this had been four wee beforehand. He had paid her passage. She had "r exactly" meant to set up house with the doctor Canada ; she supposed she would have had to wo They had corresponded regularly up to April, a she had brought some of the letters with her. Althou they had been great friends, more than doctor a patient, immoral relations had only started after husband had left her and divorce papers had be served. Asked if she had had any affection for t doctor before that, she said that she could har say.

At this point the Council's solicitor proposed to a the witness to produce some letters which she h brought with her. Mr. Slade objected ; copies these documents had not been shown to the defe and their contents were unknown. He did not fo moment imagine that they contained admissions adultery post petition, but if they did, and he h seen them, he would have conducted the case ve differently. In the High Court they would not admissible. The President ruled that the Council w entitled to hear the opening words, but not t substance, of the letters.

The Council's solicitor, after pointing out that t tenour of the accused practitioner's affidavit was t he had been unable to shake off Mrs. Dee with leaving England, and that he was building up practice in Montreal and living with his wife a children, read the opening paragraphs of the lett One began : "My darling sweetheart Nance." T letter was dated Nov. 23rd, and expressed gr

ffection ; the writer spoke of " sacrificing his career " r the recipient and of sending someone over to ask she would still have him. Another, dated Oct. 26th, 926, began " My own darling sweetheart," and the eginning of a third dated April 24th, 1927, was ouched in the same terms. None of them appeared have any signature or ending.

Witness, in answer to the Council's solicitor, stified that these letters were in Dr. De Boissière's ndwriting. Envelopes were also produced.

Cross-examined, Mrs. Dee admitted she had used r maiden name before the decree nisi had been nounced. She stated that it would be incorrect to y that her friendship with Dr. De Boissière had not iginated when he had first attended as her medical viser. Asked whether her adultery with him had t arisen out of a friendship commenced many years fore the professional relationship began, she said e used the word " friendship " in contradistinction " sweethearts, or something like that." She denied ultery before the petition, but declined to answer e question of whether it had occurred on the boat ing to Canada. She admitted she did not wish the uncil's solicitor to understand that it had. Asked y she had written to her husband asking for a onciliation and regretting her action, she replied at she supposed the voyage and the gale at sea had set her ; the expression " it nearly broke my art " referred to her parting from her child. She s prepared to swear that Mrs. De Boissière had vised her to go to Canada with the doctor much er than August 8th. She denied that the doctor had ared his cabin with another man ; he had objected having to share it and had been allowed to change. e had shared her cabin with another woman. Her th had been reserved some four weeks before the ling ; she had not said Mrs. De Boissière had been sent with them, but that she had been in the same lding.

Mr. Slade : When did you first start to become sterical ?—I can't remember that, can I ?

think you told us that your baby was taken away m you on August 9th ?—Yes.

And did you then start to become hysterical ?— e second time, yes.

When was he taken away from you the second e ?—About a fortnight after that date, but I can't member much about it. I was ill ; I can't remember exact date. Witness added she had been ill for ny days after that.

Tell us when you allege that misconduct took place ween you and the doctor for the first time.—I don't member. When pressed the witness said : After the orce papers were served ; is not that near enough ? sailed on Oct. 7th, so it must have been some e between those two days. Her husband, she said, not continued to employ Dr. De Boissière as his fessional attendant after August 9th. Questioned, stated that on one occasion she had found her sin, the witness for the petitioner, in her husband's s, and her cousin used often to go into his bedroom. had, however, suspected nothing. She had atened to defend the suit, but it was not true that husband had said : " You must not do so because will bring your cousin's name into it." When d with her statutory declaration, in which a age to this effect occurred, she explained that her on for making this statement had been that her band had gone home to her people and she was cut rom them. It was just local gossip. The cousin, however, come back to be near her husband. ed whether her husband had remarried she said knew nothing of him.

ow many times did you see the doctor between interview of August 8th and Oct. 7th, when you sailed ?—More or less every day.

here do you say this misconduct took place ?— pressure) In a friend's flat.

nd what is the name of the friend ?—I am not g to say that.

ow many times did misconduct take place ?—I d not tell you.

So you cannot tell us the date, nor how many times, and you say it was neither in your own flat nor in the doctor's house. And it is on those grounds that you are asking this court to understand that Dr. De Boissière committed adultery with you ?—No. I said that my last wish was to see Dr. De Boissière struck off the Register.

Re-examined, she stated that her husband had given her no money on parting, but that Dr. De Boissière had paid her passage ; not at the time of booking but by a cheque given the day before the boat sailed.

Questioned by the Legal Assessor, witness stated that Dr. De Boissière had been attending her family as their doctor between March, 1926, and August 9th in that year, and had attended her boy nearly every day. A member : How do you know that the letters are actually by Dr. De Boissière ?—Mr. Harper : The lady has sworn that she recognises the handwriting. Member : But three of them are unsigned.—The President : It is not proved that they are by Dr. De Boissière at all. Mr. Harper : Except that the witness has proved it on oath. Member : Are all the notes in the same handwriting ?—Yes. Member : And where do they come from ?—Montreal.

Counsel for the accused practitioner submitted that if Mrs. Dee's evidence was accepted it cleared his client of adultery before August 8th. The affidavits used to support the petition were questionable, as the suit had not been defended. He tried to hold that there had been no contractual relationship with Mrs. Dee, but the President ruled that this was irrelevant. The charge was one of abuse of professional position and did not depend on the contractual situation. Mr. Slade reminded the Council that the practitioner's affidavit had dealt with the allegations made in the petition, but not with those made that day.

Mrs. Hilda Theresa De Boissière, examined in chief, testified that she was living happily in Montreal with her two children and her husband, who was in practice there. The last entry in the day-book had been on August 5th, for Mr. Dee's son. Apart from August 8th, when Mrs. Dee had come to the house, respondent had not attended the family. After that date he had been much against any further visits to or from Mrs. Dee. At the interview at the surgery on August 8th, between the two couples, witness had not heard any words from her husband to the effect that he had committed misconduct with Mrs. Dee. Witness had seen Mrs. Dee about half a dozen times ; she had called in June and asked witness to tea. Witness had not been inclined to be friendly ; frankly, she said, on account of Mrs. Dee's reputation. Mrs. Dee had threatened suicide in witness's presence, and in that of two other witnesses, and had behaved irrationally, trying to drink the contents of empty bottles. She had said that this was because respondent had ceased to be her doctor. Mrs. Dee had asked witness on August 8th to give up her husband to her ; witness had flatly declined. After the " nitric acid " incident (an alleged attempt at suicide) respondent had said that at first he had been sorry for Mrs. Dee—he had a very sympathetic nature—but that he could not then go out of doors without meeting her. She had made a continual threat of suicide. Her husband's cabin had been also occupied by a gentleman, and Mrs. Dee had shared her cabin with an old lady. Mrs. Dee's passage had been booked the day before the boat had sailed. Respondent had often expressed the wish that Mrs. Dee should not be allowed to land, and witness's sister had succeeded in having her stopped. The letters addressed to Mrs. Dee were actually in the respondent's writing. Witness repudiated Mrs. Dee's statement that witness had advised her to go to Canada with respondent. Witness had gone to Montreal to get the house ready for her husband, not to join her mother in the States. Respondent had joined witness on the day he had landed, and they had lived very happily together ever since, as they had before. She was convinced of her

husband's innocence, and had come from Canada to give evidence for him. Under cross-examination witness stated that her husband had not paid Mrs. Dee's passage. She had not seen his replies to letters threatening suicide. He had asked her advice, as he had been afraid of public censure if the threat was carried out. Questioned by the Legal Assessor, witness admitted not knowing whether respondent had booked Mrs. Dee's passage, nor whether the other gentleman had actually occupied his berth in respondent's cabin. She had offered to help her husband defend the divorce, but he had been afraid of publicity, and Mrs. Dee's suicide, and they had both been anxious to get away to Canada, where they had lived before. Even if he had proved his innocence "it was never very nice"; the stigma would remain.

Mrs. Alexandra Wallace testified that, on verbal instructions given by respondent two days before he had sailed, she had informed the Canadian Pacific office of the affair. She had afterwards heard, she believed from her sister, that Mrs. Dee had been deported, presumably in consequence of the steps she had taken.

This witness was closely cross-examined by the Legal Assessor on her exact reasons for taking this action, and on the precise information she had given to the lady superintendent at the Canadian Pacific Office, and on what steps had then been taken. She pleaded inaccuracy of memory, but re-stated that Dr. De Boissière had told her to have Mrs. Dee stopped if possible, that she had told the superintendent, whom she had met once before when she had visited the office with Mrs. De Boissière to book this lady's passage, that Mrs. Dee was travelling in her maiden name, and that the superintendent had been indignant. She could not remember, she said, whether she had spoken about the divorce proceedings, and did not know what steps the company had taken to have Mrs. Dee prevented from landing.

Counsel for the defence, in his address, said that dealing first with the facts, the learned judge who heard the divorce suit had been asked to accept as evidence of adultery the alleged remark of the doctor at the interview; "No, Mr. Dee, it has gone further than that," an admission which Mrs. De Boissière said had never been made, and which she would have remembered if it had been made. There was therefore no credible evidence of adultery before the petition. Nor did the letter written by Mrs. Dee on her journey home afford any evidence against his client, and if his client had been at the trial it would never have been taken as evidence by the judge and jury. It gave the reason for her distress as the rough weather, and could only have been meant to convey one impression. Its writer was scorned, angry, and vicious, and had been turned back from Canada; she had meant to convey by it that she had committed misconduct on the boat. Mrs. Dee could not, or would not, say when or how often she had acted immorally. The mere fact that she had booked her passage as Miss Davis would have been sufficient grounds for stopping her. Her letter contained the phrase "the wrong I did you." She swore she had done no wrong before the petition. She had not defended the action, obviously because she was pursuing the unfortunate doctor and wanted freedom from her husband. As for the evidence of the girl cousin, it was incredible, and could only have one explanation, that the witness had desired Mr. Dee's attentions. Moreover, it had been material elicited by questions of the most leading kind. Assuming that the doctor was anxious to defend and that Mrs. Dee was anxious not to, his position was impossibly difficult. Every professional man knew that to be "mixed up" in a case was only one shade better than to be actually guilty, and that innocence went for practically nothing. The action of the doctor in leaving the suit undefended might have been misguided, but it was perfectly compatible with his innocence. Mrs. Dee's word was the only evidence against the doctor, and if it were to be believed, it must be taken in his favour as well.

On the second charge, that of post-petition adulter the only evidence was again that of Mrs. Dee. It w upon the instructions of Dr. De Boissière that Mr Wallace, unless this witness was deliberately lyin had had Mrs. Dee stopped. That meant either th the request had been a blind—in which case the doct was an extraordinarily fine actor—or that he had be genuinely anxious to get rid of the woman; this w the only possible explanation. It was natural tha after being slighted in this way, Mrs. Dee shou express some animus. On the question of the profe sional relationship, counsel held that the friendsh had originated in 1918, as Mrs. Dee's declaration ha stated, and that the professional relations had be incidental and had terminated in August, 192 Adultery was not necessarily infamous conduct, and young man who met a woman of far stronger charact who must have wanted him, or she would not have l her husband divorce her, who pestered him a threatened suicide—and who fell into immo relations with her, was not to be classed with a we established man who abused his professional positi to commit adultery.

Mr. Harper, for the Council, said that the friendsh that commenced in 1918 could not be taken in account. The accused practitioner's affidavit contain a very remarkable phrase. "There was no illicit a wrongful relationship . . . at the time complain of"; he had not made the denial absolute. He h been composing the affidavit with the help of his wi who could not have known half the story. T attempts to prevent Mrs. Dee landing must ha emanated, not from the doctor, but from his fami Mrs. Wallace had testified under cross-examinati that the doctor and his wife were not cohabiting, a therefore there must have been trouble between the When the defence had stated that there was evidence except that of Mrs. Dee, they had r referred to the letters, which Mrs. De Boissière h seen that afternoon for the first time. It had be admitted that her husband had read her a paragra of one of the letters that he had written to Mrs. D but not that he had shown her a letter. These lett seemed to him, the solicitor, to destroy any credit t might be placed on Dr. De Boissière's word, and indicate that the charge was well founded.

After the Council had deliberated on the case camera the President announced: "Mr. Slade: I have to inform you, on behalf of your client Mr. Boissière, that the Council have found that the fa alleged both in the first part and in the second p of the charge set out in the notice of inquiry have b proved to their satisfaction and that they h pronounced judgment on the facts so proved. Th judgment is that Mr. De Boissière has been guilty infamous conduct in a professional respect, and th have directed the Registrar to erase from the Regis the name of Vernon Raymond Joseph De Boissièr"

THURSDAY, NOV. 24TH.

The Case of Victor Thomas William Eagles, M registered as of 39, Linwood-road, Bournemou L.R.C.P. Edin. 1912, L.R.C.S. Edin. 1912, L.R.F.P Glasg. 1912. Respondent had been summoned be the Council on the following charge:—

That you were on August 9th, 1927, convicted at Witham Petty Sessions of the following misdemeanou namely, of being drunk whilst in charge of a motor- and were fined £30, ordered to pay £3 10*s.* costs, and qualified from holding a driving licence for two years.

The Council's solicitor said that it was unusual the Council to summon a practitioner for one con tion, but that this had been rather a scandalous c He read extracts from the proceedings before magistrates. Dr. Eagles had turned his car over striking a bank while in a state of intoxication.

Respondent denied drunkenness and pleaded error of judgment in driving. He had driven ag later on the same night. He suggested that the he sentence had been due to the fact that the chairm of the sessions had been a medical man, and he sta

at he had been the victim of police methods. In swer to the President, he admitted that he had sited a number of public-houses and had a reasonable antity of drink. He had pleaded guilty because he d not wanted the lady who had been his companion be summoned as a witness, but had altered his plea hen she was called. The Council, while considering conviction of this kind discreditable to both a actitioner and his profession, decided in view of the arning the respondent had received not to order the asure of his name.

The Case of John Joseph Macabe, registered as of 58, unswick-street, Chorlton-on-Medlock, Manchester, B., B.Ch. 1918, N.U. Irel. Mr. Macabe had been nvicted once of assault and four times of drunken- ss, between 1920 and 1926 inclusive. Respondent mitted that he had committed all the offences but at of assault. He had not been engaged in any ofessional work at the time. Since his student days had been unable to carry drink. He assured the uncil that he had determined to abstain from it, d produced recent testimonials to his good pro- sional conduct from medical men with whom he d been associated. The Council postponed judg- nt until their session in November, 1928, with the stomary proviso and warning.

The Case of Bernard Wilfred Goldstone, registered as 14, Menelik-road, Cricklewood, N.W. 2, M.R.C.S. g. 1926, L.R.C.P. Lond. 1926. Respondent peared before the Council on the following charge :—

That, being a registered medical practitioner, you abused ur position by committing adultery with Mrs. Theresa ris Froomberg, a married woman, with whom you stood in fessional relationship, of which adultery you were found lty by the decree of the Probate, Divorce and Admiralty ision (Divorce) of the High Court of Justice, dated y 25th, 1927, in the case of Froomberg *v.* Froomberg Goldstone, in which you were the co-respondent. l that in relation to the facts so alleged you have been lty of infamous conduct in a professional respect.

The respondent was accompanied by Mr. Oswald mpson, solicitor. The complainant, Mr. Froomberg, s represented by Mr. E. L. D. Zeffert, solicitor. . Zeffert, in his opening address, stated that the y relevant issue was that of whether a professional tionship had existed ; adultery was admitted. plainant, a merchant in the City, had been rried in 1922 and his work took him away from ne one week in three. In August, 1926, during ir holidays at Le Touquet, Mr. and Mrs. Froomberg l stayed in the same hotel as the brother of the used, who was engaged to be married to a sister of s. Froomberg. Dr. Goldstone had spent one night h them on his way to Germany. He had then made acquaintance of Mr. Froomberg and renewed his ndship with Mrs. Froomberg, whom he had known a child. He had on that occasion prescribed a nacetin and caffein powder for her, as she had plained of headache while out walking. Acquaint- eship had been next renewed at the house of Mrs. omberg's mother and continued at parties held he houses of both families. At the end of November s. Froomberg had fainted at her mother's house Dr. Goldstone had been summoned by his brother attend her. Mrs. Froomberg had been in good lth, but subject to headaches and fainting fits : had been under the care of a Dr. Morton, but had suaded her husband to put her under the care of Goldstone as well. It would be proved that Dr. dstone, by reason of his medical qualification, and he request of Mrs. Froomberg, had been allowed ess to the house, her bedroom, and her person. prescriptions had been set out in the statutory laration and another had been discovered since. y were dated Feb. 15th, 1927, March 20th, and l, 1927. Dr. Goldstone had also attended and scribed for a servant in the house in March. ing all this time there had been adultery, and early April Dr. Goldstone and Mrs. Froomberg had gone oad together.

Mr. Joseph Froomberg, examined, confirmed the y as outlined above. He said that his wife had had great faith in Dr. Goldstone's capabilities, but he had had more faith in Dr. Morton. As she had suffered from nervous attacks he had allowed Dr. Goldstone to treat her, in spite of the fact that Dr. Morton had been attending her at the time. He had also visited the house socially.

Replying to the Legal Assessor, he said that Dr. Goldstone's treatment had commenced in November, 1926.

Continuing in reply to his solicitor, he said that Dr. Goldstone had at first attended once in three or four weeks, but later, after January, 1927, perhaps once a fortnight, to his own personal knowledge. He could not vouch for what had happened in his absence. He had left the room when Dr. Goldstone and Dr. Morton had attended professionally, but had been present at social visits.

Cross-examined by Mr. Hempson, witness denied that the discovery of the prescriptions was his only reason for saying that Dr. Goldstone had attended his wife professionally. He agreed that at Le Touquet Dr. Goldstone had not been registered, having just passed his final examination. He repudiated the suggestion that Dr. Goldstone had only attended Mrs. Froomberg professionally on three occasions (the headache at Le Touquet at the end of July, the fainting fit at her mother's in November, and the attack of influenza in March) and also that he had only entered her bedroom once, on the last occasion. He had himself shown Dr. Goldstone into Mrs. Froomberg's room on several occasions, " round about January and February, not very often perhaps, but on one or two occasions." Dr. Morton had been their regular medical attendant and had attended throughout this period. Dr. Goldstone had never rendered an account, though he, witness, had mentioned it several times, approximately every time Dr. Goldstone came to the house professionally. The reply had been something like " no hurry " or " don't bother." Mr. Hempson suggested that it was extraordinary that no mention had been made of these facts in the statutory declaration prepared for the Council. Mr. Froomberg replied that he had very little to do with legal affairs and had signed what his solicitor had prepared. He had declared what he thought was of material importance.

Why, then, did you not include this in your declaration ?—It probably did not occur to me.

There, we have " probably " again.—Because it did not occur to me to include it.

Knowing what you were charging him with ?—Yes. I did not think he would defend the case.

That declaration was made as carelessly and lightly as that ?—I do not think you ought to put it like that.

I put it that that declaration is true as far as the exhibits are concerned ?—What is in the declaration is perfectly true, but that does not say that what I have said now is untrue.

I am suggesting that what you have added to the declaration now is not a fact. You never brought this out in the first proceedings, did you (i.e., before the Divorce Court) ?—It was not necessary ; the only thing necessary to prove was the adultery.

You must take it from me that there is no mention in the petition of the fact that Dr. Goldstone is a medical man ; I am suggesting that it was not mentioned because that relationship has never existed ?—The suggestion is ridiculous.

Witness did not agree that it was a strange coincidence that his statutory declaration only alleged professional attendance during the two months of the dates of the prescriptions, and held that Dr. Goldstone and his wife could not have met socially outside his house more than about once a month during 1926, though they had met more often after January, 1927.

The suggestion is that it was the professional relationship that brought about the friendship ?—That is true. No, I should not say that that was true altogether. It is true of my own friendship with Dr. Goldstone, but I should not think it was true of my wife's friendship.

Did you ever explain to Dr. Morton that somebody else was attending Mrs. Froomberg ?—No, he knew nothing of it.

And he frequently came to the house ?—Yes.

Was this treating Dr. Morton fairly ?—It was not a question of treating Dr. Morton fairly as far as I was concerned. My wife had more faith in Dr. Goldstone and she was of a very difficult temperament.

And yet you never explained that to Dr. Morton ?—No.

If it was true, did it not occur to you that the treatments might not agree one with another ?—Dr. Goldstone was perfectly aware that Dr. Morton was attending to my wife.

But the other way did not occur to you—that Dr. Morton's treatment might be affected by Dr. Goldstone's prescribing for her ?—Dr. Morton offered to prescribe for my wife, but my wife never took the medicines.

Is that your reason for not telling Dr. Morton ?—No, I wanted Dr. Morton to keep an eye on her.

The question I put was this : did it not occur to you that the medicine that was being prescribed by Dr. Goldstone might have handicapped Dr. Morton in his treatment of Mrs. Froomberg ?—It might have occurred—it did occur to me—but I am afraid I did not have my own way in that respect.

And despite that you did not tell him ?—No.

Again I suggest that the reason for that was that there was no professional attendance by Dr. Goldstone.

Witness agreed that Mrs. Froomberg had confessed to adultery from the beginning of December.

Mr. Zeffert produced a letter from Dr. Morton saying that there had been no attendance on Mrs. Froomberg in January or February, but the President refused to admit it as evidence.

Questioned by the Legal Assessor witness said that he had definitely placed his wife under the care of Dr. Goldstone "about January."

The Legal Assessor : That being so I do not quite understand your declaration. It was put to you, you know, that you knew what the declaration was for, the purpose for which it was made ; for these proceedings, and the charge in these proceedings was that Dr. Goldstone had abused his professional attendance on your wife. You knew that that was the ground of the charge ?—Yes.

Will you now kindly look at your para. X. : "In the months of February and March the said Bernard Wilfred Goldstone attended my wife as medical practitioner." Did you mean to imply by those words that that was the only time on which he had attended her ?—No. I might have said "January, February, and March."

You might have said many things. Did you mean to imply by those words that that was the only time that this doctor had attended her ?—No.

Then why did not you declare that you had put her under treatment in the beginning of 1927 ?—The reason for that is that in the early part of 1927 it was just very rarely, perhaps once in three weeks, that he did attend to her. That might have been once in January, but during February and March, which were much more important months, he was in the house once or twice a week.

I want some explanation in answer to my question as to why you merely state there that he attended her in February and March, if you do not mean to imply that that was the only time ?—The reason why I put in February and March was that during February and March he attended her very frequently, whereas previous to that it was the reverse—occasionally. Sometimes a doctor might come and not come again, or you might change your doctor.

Was it because February and March coincided with the dates of the prescriptions that you had found subsequently to your wife's leaving you ?—No.

You exhibited them to point the date when she was being attended ?—Those happened to be two prescriptions found in the house, and naturally I put them in the hands of my solicitors. There were others, I believe.

Knowing the gravity of the charge, you said nothing about putting your wife under the charge of the doctor during January, 1927 ?—No. Perhaps he only visited her once during that month.

In answer to questions put by the President, witne said that he had shown Dr. Goldstone into th bedroom on one Sunday afternoon ; on other occasio he had been out, and could not state the time of da Dr. Goldstone had not sent in a bill for attendance the maid, as this was just before he had eloped. D Morton had not ceased attending Mrs. Froombe during January, February, and March ; he had call once in two, three, or four weeks and was the regular practitioner. He had attended witness a his child, and witness had insisted that he should al attend his wife, and had actually seen her. He cou not remember whether or not he had received account from Dr. Morton. He had sent for Dr. Mort to visit his wife during those three months. He h never sent for Dr. Goldstone in the same capacit Dr. Goldstone had usually come at his wife's reque

Questioned by a member of the Council, through t President : Did he in fact ask Dr. Goldstone to ta charge of his wife ?—I did not ask Dr. Goldstone take charge of my wife medically. My wife asked hi herself.

Did he authorise his wife to have Dr. Goldstone a medical attendant ?—I did.

Mrs. Elizabeth Roots, examined, said she had be house-parlourmaid in Mrs. Froomberg's house duri the winter of 1926–27. She had admitted D Goldstone to the house. Sometimes he had be treated as other visitors and sometimes he had co as a doctor ; she thought he was a doctor on the occasions because he had brought his bag. He h attended Mrs. Froomberg in her bedroom constant for one week, and occasionally at other times. D Morton had also called and seen Mr. Froomberg January and February.

Cross-examined, witness said she had shown D Goldstone to Mrs. Froomberg's bedroom about two three times in the week of constant attendance, ju before Easter. Pressed, she said she had shown hi to Mrs. Froomberg's bedroom altogether about a doz times. She could give no precise dates.

There was no statutory declaration from this witne

Mr. Hempson put it to her that she had only sho Dr. Goldstone to Mrs. Froomberg's room on o occasion. She replied : "I showed Dr. Bernard more than once."

Replying to the President, she said Dr. Goldstone h usually called about tea-time, and Dr. Morton in t morning.

Miss Beatrice Ashby, cook at Mrs. Froomberg house, described Dr. Goldstone's attendance on hers at the end of March.

Dr. Goldstone, examined by Mr. Hempson, sa that he was 24 years old and that he had known M Froomberg as a child. He had renewed the acquai ance at a party held at her mother's house to celebra the engagement of his brother to her sister. He h then met Mr. Froomberg. About a fortnight later had been invited to a party at their house. They h subsequently met at the weekly "At homes" of th respective mothers, and again at Le Touquet August 3rd, 1926. He was then unregistered, thou qualified. He had given her a prescription phenacetin, aspirin, and caffein while walking alo the road, there had been no consultation, and no qu tion of remuneration. He had seen them fairly f quently after his return from Germany in Septemb and had become friendly with Mr. Froomberg. O night in November he had been working at ho when a telephone message came from his brother th Mrs. Froomberg had fainted at her mother's hou He went round, but she had recovered, and he gave prescription. Mr. Froomberg, witness's brother, a witness had taken her home in a car and carried h up to her room. He had never regarded himself her medical attendant. When, on a very few occasio Mrs. Froomberg had talked to him about her hea he had always asked why Dr. Morton had not be consulted. On one or two occasions they had be unable to obtain him ; on others they had said had not been called in, but witness had subsequen discovered, to his annoyance, that in fact he had be

mmoned. His attendances on Mrs. Froomberg, in y sense professionally, certainly would not run into o figures. The prescription dated Feb. 15th, 1927, s one for ergot and sulphuric acid ; Mrs. Froomberg d complained to him of menorrhagia, when he was ving tea with her that day, and had asked him he could do something for her, as she was feeling ther bad. There had been no subsequent attendance. that time he was attending at the hospital out-tient department ; he had done a locum for three eks at the beginning of the year, but had otherwise d no professional work. The second prescription, ted March 20th, was a simple diaphoretic (pot. acet. d inf. buchu). He had been rung up by someone—t Mrs. Froomberg herself—to ask him to call and her. He had asked about Dr. Morton and they had d they had been unable to get him. He had seen s. Froomberg in bed and found she had influenza. had stayed to lunch with Mr. Froomberg. Three ys later he had prescribed a tonic for her. This scription was dated March 23rd and contained ct. nucis vom. and liq. arsenic. He could not recall y other professional services to Mrs. Froomberg, ugh he admitted there must have been some. ey were isolated and unimportant incidents, such headaches, mentioned while he was visiting socially. had often visited socially, but it was impossible t he could have visited professionally often ; there been no protracted illness other than this influenza matter of two visits. He had known that she was ler the permanent care of Dr. Morton. It had er entered his head to send in an account for these vices, and Mr. Froomberg had only mentioned a once. He had said " I suppose I ought to pay for this," and witness had replied " Nonsense." was honestly of the opinion that he had never n sent for professionally on any occasion other n those mentioned. It was absolute nonsense to that he had been shown to Mrs. Froomberg's room on 12 occasions. He had met Mr. Froomberg quently during this period, at his house and at the ses of witness's mother and Mrs. Froomberg's her. He had visited Miss Ashby in her room after aint, accompanied by Mrs. Froomberg, and had ured her admission to the Middlesex Hospital. ercourse had first taken place between Mrs. omberg and himself in the beginning of December. en he had first found that he had formed an attach-t for her he had wanted to go away at once, but had refused.

ross-examined, he put the date of the first adultery Dec. 3rd, which was before Mrs. Froomberg's ting fit. It had occurred at Mr. Froomberg's se, in the late evening.

his was on the occasion of a social visit ?—It ainly was not a medical visit.

s far as the servants were concerned ?—I never d the servants' opinion of it at all.

n what part of the house did it take place ?—nstairs.

fter the servants had gone to bed ?—I never ced.

re we agreed that up to that time Mr. Froomberg's aintance with you was of the slightest nature ?—we are not agreed.

ill you tell me when your relationship with Mr. omberg became of a friendly nature ?—That is a l thing to define.

put it to you this way, that from and after the of the fainting fit, until you went away with Froomberg, you were as an honoured guest in ouse, and he treated you as their friend. And it erfectly true that, during the whole time, you seducing his wife, and do you know that the ital relationship between husband and wife was ectly normal as far as Mr. Froomberg was aware ? knew nothing about it.

ou knew at that time you were deceiving Mr. omberg ?—Yes.

ou have betrayed his hospitality ?—Yes.

he case against you is that you were using your ical qualifications to deceive Mr. Froomberg and the two servants to obtain access to the person of Mrs. Froomberg ?—I did not know that was the case against me.

But you will agree with me that Mr. Froomberg, by reason of your medical qualifications (and the two servants), permitted you free access to the person of Mrs. Froomberg ?—Not by reason of that.

Do you think, Sir, that if you were an ordinary member of the public you would have been admitted to the person of Mrs. Froomberg ?—I am certain of it.

Do you agree that Mr. Froomberg is a clean-living man ?—I know nothing about Mr. Froomberg's private life.

You have heard nothing from Mrs. Froomberg about it ?—No. I would not be bothered about that sort of thing.

Pressed to cite something from Mr. Froomberg's evidence that was untrue, witness pleaded poorness of memory, and finally quoted the statement that witness had visited his wife professionally many times. Although pressed, witness said he would stand or fall by his statement that it was not Mrs. Froomberg personally who rang him up on the Sunday of the influenza attack, and that if he had visited her on March 21st or 22nd her husband had been in the room at the time.

Do you mean to say that those servants would have allowed you the run of the house if you had not been a doctor ?—They only started calling me " doctor " after I had treated Miss Ashby.

But you did not treat Miss Ashby until you had determined to take Mrs. Froomberg away with her husband's money ?—I did not take Mrs. Froomberg away with her husband's money.

Did you go away with your own money ? Did you support her ?—Yes.

Solicitor then produced a small diary. Mr. Hempson pointed out that he had not hitherto seen this exhibit, and was allowed to examine it.

You have received letters from Mrs. Froomberg ?—Two, I think.

Is that Mrs. Froomberg's handwriting ?—I don't know. I dare say it is. I have not seen enough of her handwriting.

Do you swear that you do not know her handwriting ?—" Know " is a word I do not understand. If you wrote to me I could tell it was not Mrs. Froomberg's handwriting.

Look at that handwriting. Just answer me, Is that Mrs. Froomberg's handwriting ?—I do not know.

You have seen her write letters ?—I have not watched what she has been writing.

And you expect this Council to believe that you do not know her handwriting ?—I do not expect things to be believed or not. I am speaking the truth.

In answer to Mr. Hempson, witness said that he was known to the maids as " Mr. Bernard " up to the date when he attended Miss Ashby, and after that as " Dr. Bernard."

In answer to a question through the Chair, witness said that he had made no physical examination when he had prescribed the ergot mixture.

The President : Have you got into the habit of ordering ergot for lady friends who are not your patients ?

Witness : No, Sir. As a matter of fact, I looked up the dose in my Pharmacopœia.

Mrs. Theresa Doris Froomberg, examined by Mr. Hempson, confirmed the evidence given by Dr. Goldstone.

It has been put by Mr. Froomberg that in December or January you asked that you might be attended by Dr. Goldstone as your doctor. Is that correct ?—No.

Was he your doctor at that time ?—No.

It has been said also that he visited you professionally about once in three weeks, throughout January, until about the middle of February, and thereafter two or three times a week, professionally. Is that correct or incorrect ?—It is quite incorrect.

It is also said that on 12 occasions he was shown up to your room by your housemaid during that period

of three months. What do you say to that ?—That it is not true.

She described the circumstances under which the prescriptions had been given in the same terms as Dr. Goldstone had done.

Do you remember being ill on March 20th ?—Yes.

What steps did you take to get medical attention ?—I was in bed in the morning. My little girl's nurse came to see me. She said I did not look well, and she took my temperature, which was about normal, and said I had better have the doctor. She tried to get Dr. Morton and he was out. Then she telephoned to Dr. Goldstone.

The President: Did you tell her to ?—Yes.

Under renewed examination witness said Dr. Goldstone had visited her again on the Monday and on the Wednesday. The only other medical services rendered by him were on the occasions of fainting attacks occurring when he was present. It was not true that he was attending more or less regularly throughout that period as her medical attendant. She did not look on these services as professional in the sense that they were to be remunerated. He had attended Miss Ashby as a doctor. He had always been known to the maids as "Mr. Bernard."

Under cross-examination, witness identified her handwriting in the diary and said the entry was written out at the time. Solicitor read out the entry of March 20th: "Felt rotten this morning, so rang Bernard up and he said I had flu. Joe played golf. Bernard stayed to lunch. Joe and Bernard went up West together, and did not return till 6." March 22nd: "Bernard came in to see me early this evening. I can go downstairs to-morrow."

Would you describe Mr. Froomberg as an ordinary clean-living business man, leading an ordinary life, truthful, honourable ?—Yes.

Mr. Hempson: In spite of that would you say that the evidence given by him to-day was true ?—Yes, except for the question of attendances.

Did you or did you not send for Dr. Goldstone for that trouble on the 26th (March) ?—I did not.

Why not ?—Dr. Morton was my medical attendant.

He was available when you rang ?—Yes.

Can you tell me of any other date whereon it is recorded (in the diary) that Dr. Goldstone attended you professionally ?—I can't.

Or in a medical capacity ?—No.

In answer to a question through the Chair witness said that sexual relations began at the end of November or the beginning of December, before the date of the fainting attack at her mother's house.

This closed the evidence. The two solicitors addressed the Council on Friday, Nov. 25th, and after deliberation in camerâ the President announced the verdict in the following words:—

"Dr. Goldstone, I have to announce to you that the Council have found the convictions alleged against you in the Notice of Inquiry to have been proved to their satisfaction. They have found you thereupon to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase your name from the Register."

The Case of Harry Simpson Harling, registered as of 102, Skipton-road, Ilkley, L.R.C.P. Edin. 1909, L.R.C.S. Edin. 1909, L.F.P.S. Glasg. 1909. This practitioner was also charged with abusing his professional position to commit adultery. He did not appear in answer to his notice, and the Council, on hearing the representations of his legal adviser, adjourned the hearing of his case until their May session next year.

The Case of Robert Moore, registered as of 34, Mawney-road, Romford, M.B., B.Ch., M.D. 1905, U. Dubl., and *the Case of John McGhee*, registered as of Station-road, Galston, Ayrshire, M.B., Ch.B. 1923, Glasg. Both these practitioners had convictions proved against them of being drunk in charge of motor-cars; Mr. Moore had been also convicted of driving to the public danger on another occasion, and Mr. McGhee of drunkenness. The Council suspended judgment for six months in each case.

FRIDAY, NOV. 25TH.

REPORTS OF COMMITTEES AND OTHER BUSINESS.

Restorations.

After consideration in camera, the Council decid to restore to the Register the names of Willi Lloyd, registered as of 58, Brook-street, W. Sydney Edgar Price, registered as of 77, Lov Hollyhedge-road, West Bromwich, Staffs; a George Joseph Mary Fraser, registered as of Fitzwilliam-place, Dublin, erased under the pe section of the Medical Act.

Removal of Name at Practitioner's Request.

The name of Henry Bown, registered M.R.C.S. E 1926, L.R.C.P. Lond. 1926, was removed from Register at his own request, on the ground that had ceased to practise.

Nominations to Committees.

Education.—Sir Farquhar Buzzard and Dr. Lorr Smith, nominated by the English and Scottish Bra Councils respectively, replaced Mr. Thelwall Thon and the late Dr. H. Littlejohn.

Examination.—Dr. J. S. Stopford replaced R. B. Wild as representative of the English Bra Council.

Public Health.—Dr. Lorrain Smith replaced late Dr. Littlejohn as representative of the Scott Branch Council.

Education Committee.

The Chairman of the Education Committee, Humphry Rolleston, laid before the Council Friday morning, Nov. 25th, two important repo one on the amended regulations for the registratio students, and the other on the progress made throu out the country towards the readjustment of medical curriculum in accordance with the resoluti of the Council passed on May 26th, 1922. The sec of these reports is a pamphlet of about 200 pa and contains the replies of all the licensing corp tions to the Council's recommendations, with comments of the Education Committee thereon. the bodies, with the one exception of St. And University, have modified their curricula as a re of the suggestions of the Council. After a sli discussion of details both reports were adopt the second is to be sent to all licensing bodies, their observations embodied later in another do ment. In another issue we hope to deal more f with this important subject.

MEDICINE AND THE LAW.

British Medical Association v. *The "Daily Ne Limited.*

IN the King's Bench Division, before the Lord C Justice, on Nov. 29th, this case was mentioned, w it was announced that the action had been sett the defendants agreeing to publish a disclaimer.

The defendant company are the proprietors of *Star* newspaper, and on Sept. 2nd, 1926, the follow article appeared:—

Our American cousins have an expressive figure of sp about the man who "bites off more than he can ch It might be applied with justice to the British Me Association. While it confined its oppressive activitie bone-setters and other unregistered practitioners who c be dubbed quacks without fear of legal reprisals it was to get away with it. Any criticism of its conduct coul contemptuously swept aside as the uninformed preju of the mere layman. When, however, it tried to disci distinguished members of its own body it did in fact off more than it could chaw. Sir William Arbuthnot L the President of the New Health Society, is the case in p at the moment. The B.M.A. does not like the society its motto is "Prevention rather than cure." To pr "health without doctors" is the unforgiveable sin to medical monopolists, who have in the past imposed a rigid etiquette of secretiveness on their close profes Sir William appears to have had the courage to defy t

ut-of-date conventions, and, contemptuous of the B.M.A.'s ower to strike him off its register, is reported to have struck mself off. The B.M.A. can do—just nothing.

Mr. Stuart Bevan, for the British Medical Associaon, described that article as seriously defamatory the Association, and of its policy and of its methods, e whole of the comments being entirely unjustified. n the institution of proceedings, without waiting r the action to come to trial, the defendants' advisers bmitted to the plaintiffs the following statement hich was read in court :—

It has been pointed out to us that an article published the *Star* of Sept. 2nd, 1926, on the subject of the New ealth Society and the retirement of Sir William Arbuthnot ne (first President of that Society) from membership the British Medical Association, has been construed imputing improper motives and behaviour to the British edical Association—particularly that the Association s oppressive upon medical practitioners, registered as ll as unregistered; that its hostility to the educative thods of the New Health Society arose from a desire to event any improvement in the public health because is would involve loss of fees to medical men; and that e Association was actuated solely by the desire to benefit e medical profession without any regard whatever to public alth or public interest.

We disclaim the intention of making any such imputaons, and we are fully satisfied that such a conception of e work and outlook of the British Medical Association uld be wrong in fact and unjust; and we regret any ong impression which the publication of the article may ve created.

Mr. Bevan then pointed out that the Associaon has itself been much concerned—and has used research work to be undertaken—in the evention of disease. Mr. Norman Birkett, for e defence, said that he agreed with the statement the terms of settlement.

His lordship indicated his assent to the discontinuance of the action, each party being content to ar its own costs.

Damage from Horse-bite.

If a horse bites other horses is it to be deemed ely to bite human beings? The old idea that an imal is "allowed one bite" received fresh illustran lately in the High Court in the following circumnces. A man was crossing Ludgate-hill and passed front of a stationary horse and van which were at e moment unattended. The horse was muzzled, t stretched out its head and made for the passenger's ad, thereby injuring his face. Evidence (to prove at lawyers call the *scienter*) was called to establish t the horse had previously bitten another horse. jury in the Mayor's and City of London Court arded the plaintiff £25 damages, but the judge ve judgment for the defendants, and the High Court s confirmed his view. The jury had found that the rse was dangerous to other horses and also to nkind, but no evidence had been given to show t a horse which will bite another horse is likely to e a human being. People, said Lord Sterndale, R., in Manton *v.* Brocklebank four years ago, are safe in acting upon what they believe to be mmon knowledge without evidence. Lord Justice utton quoted this remark with approval and led that horses are subjects upon which people en disagree.

The plaintiff put his case in this way. Horses, as know them in the London streets, do not bite. ce you find a biting horse, you find an animal which outside its class, and therefore must be deemed ngerous in the sense that its owner keeps it at his il and is liable for any damage it may do. But, d the Lord Justice, there is no legal authority for proposition that, if an animal is known to be ngerous in one particular way, its owner thereupon comes liable for any other kind of damage it may do, wever unexpected or unusual.

Friendly Society's Convalescent Home and Income-tax.

The Royal Antediluvian Order of Buffaloes has ablished a convalescent home at Redditch largely by subscriptions from within the Order. It is supported by the general funds of the Order, and the beneficiaries must be members of the Order, though only 20 or 30 patients out of 2,000,000 members could be accommodated at a time. The General Commissioners of Income-tax made an assessment of £180 gross (£146 10*s.* net) on the premises, but Mr. Justice Rowlatt has ruled that it is a "hospital" within Rule 1 (*c*) of No. VI. of Schedule A of the Income-tax Act. The Solicitor-General, who appeared for the Inland Revenue, seems to have admitted that the fact of the institution covering only a small field of hospital work did not prevent its being a "hospital." But the Crown argued that the home was really a private establishment which the Buffaloes could close at any time and that there was no such element of public charity about it as would entitle it to exemption from tax. The judge said it was unlikely that the activities of the home would be stopped and the profits thrown into the general funds of the Order. The home was an eleemosynary establishment maintained by the Order for the benefit of a few of its members. The fact that it was limited to members of the Order made no difference. A hospital established for the members of a profession or trade was not prevented from being a hospital within the meaning of the statutory exemption.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

German Orthopædic Congress.

THE German Orthopædic Society, at its annual meeting in Nuremberg, devoted considerable attention to arthritis. Prof. Heine (Rostock) opened a discussion on arthritis deformans, which, he said, is found most often in the knee-joint and less commonly in the elbow, hip, and shoulder. The knee is never affected before the fortieth year, and the hip before the fiftieth. Up to the age of 60 the disease is more often seen in men than in women. Pathologically it is a peculiar condition of the mesenchyma, depending on age and constitution. Dr. Krebs (Aachen) pointed out that X rays do not always reveal the cause of the pain, since it is often due to alterations of the joint-capsule and of the subchondral tissue. He considered that muscular atrophy is a result not of inactivity but of atrophic disturbances of a specific character. Hyperæmia is, he said, the essential curative agent, and may be produced by mud or other baths; after treatment at Aachen, 64 per cent. of the patients are able to work. Prof. Vulpius (Heidelberg) said that when the capsule was contracted the joint should never be extended with vigour, but very cautiously. Prof. Spitzy (Vienna) advocated stretching of contractions by a single manipulation. The aim of an operation should be ankylosis in the knee-joint but mobility in the hip. Dr. Kruz (Berlin) said that in women arthritic pain in the knee-joint usually develops between the fortieth and fiftieth year, a fact probably connected with diminished resistance at the climacteric and the increase of weight at that period. In the more acute cases fixation of the joint, in chronic cases a Hessing apparatus, and in less serious cases medico-mechanical treatment, is required.

In a discussion on scoliosis, Prof. Galeazzi (Milan) explained his method of curing scoliosis by gypsum dressing in stages on a special table in the horizontal position. Dr. Gaugele (Zwickau) said that old-standing scoliosis is the result of fixation and of compression, caused by the weight of the trunk, relaxation of muscles and ligaments, and general weakness. Whilst the fixation is not remediable, compression may be influenced by a gypsum dressing; in debilitated persons gymnastics are useful. Dr. Valentin (Hanover) spoke on heritable orthopædic conditions, and said that brachydactylia, syndactylia, Dupuytren's contracture, chondrofibromatosis, and a

tendency to habitual luxation of the shoulder are often hereditary. Dr. Maus (Berlin) referred to the familiar occurrence of club-foot. It is not yet ascertained, he said, why this condition is more frequent in males than females. Dr. Brandes spoke on retarded consolidation after osteotomy, which had occurred in 6 per cent. of his 4485 operations, and in his view had local causes. Dr. Simon (Frankfort) said that this retarded consolidation is fairly common in women between the ages of 18 and 25, and is caused by reduced vitality of the sclerotic bone. Dr. Königswieder (Vienna) agreed with this statement, and advised his hearers to abstain as far as possible from cosmetic operations at that age. He believed that endocrine troubles were responsible for the retardation.

Prosecution for Injury by Neglect.

Some time ago a medical man and a nurse were found guilty of injury by neglect because the nurse had forgotten to apply the filter in using X rays for curative purposes, the result being a severe burn. The court considered that it was the doctor's duty to ascertain whether the nurse had applied the filter; he had, however, left the room after having adjusted the apparatus. On appeal the High Court in Leipzig has cancelled the verdict so far as the medical man is concerned. It regards the application of X rays as a merely technical procedure, including the use of a filter in every case, and holds that the medical man was justified in believing that it had been employed in this particular case as in any other. Administration of X rays may be likened to that of a poisonous drug; it requires certain precautions, but is, as a rule, entrusted to trained nurses, no medical man being expected to supervise their administration personally if he has assured himself that the nurse is trustworthy. The case has, however, been referred back to the local court, because it had not been made clear whether the nurse was or was not sufficiently experienced to be left in charge by the doctor.

Dental Treatment in Russia.

Prof. Dauge, of Moscow, in a paper recently read before the Society of Socialist Medical Men, explained that in Russia dentistry is regarded as a special branch of general medicine like other branches, and that the dentist is expected to be familiar with medical science as a whole. In Leningrad and other places there are stomatological clinics with large staffs where some 9000 dental surgeons have already been trained. Whereas in Leningrad there were, five years ago, about 500 private dentists, there are now only 50. Dental treatment is carried out at 12 great dispensaries maintained by the State, where the working time of the medical man is only five hours daily.

Insurance against Accidents.

According to a recent statistical report there were in 1925 837,695 industrial concerns whose employees were insured against accidents, under the Workmen's Insurance Act, to the number of 11 millions. There were also 4,601,916 agricultural enterprises with 14 millions of workers, and 880,194 employees of the State and municipalities. The total number of insured persons was thus about 25 millions, being an increase of 1 million compared with the previous year. Compensation for the first time was secured by 107,517 persons, of whom 53 per cent. were industrial, 42·6 per cent. agricultural, and 4·4 per cent. employees in public works. The percentage of compensation payments for each 1000 accidents has much increased compared with 1924. The rate per 1000 was 5·2 (4·4) among industrial workers, 3·2 (2·6) among agricultural workers, and 5·4 (4·2) for State and municipal workers, the figures in parentheses being those for 1924. The increase is partly due to legal extension of insurance to the time of transport to and from work. The accidents were fatal in 7·5 per cent. of cases, and 1·1 per cent. of them caused total incapacity for work.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Deep X Ray Treatment in Dublin.

AN improved apparatus for treatment by de X rays has been installed at the Royal City of Dub Hospital, and the treatment rooms were public opened by the Governor-General last month.

The treatment room contains a switch-table whi places the whole apparatus under the comple control of one operator. Projecting through t wall between the machine and treatment rooms a two large metal cylinders. Each cylinder, which c be raised or lowered by means of a motor mechanis contains one X ray tube, thus enabling the sim taneous treatment of two patients, who are plac on couches either beneath or over the cylinde according to the type of treatment being giv The cylinders, which weigh one ton each, are coat with lead a quarter of an inch thick, thus affordi complete protection for the operator and enabli the doctor or sister to be in close touch with t patient, heretofore impossible owing to the gra risks run from stray radiation due to imperfec protected apparatus. The facilities for treatm provided will be available for patients at ot hospitals, and also for private patients on the reco mendation of their own medical attendants.

University College Medical Society.

The opening meeting of the University Coll Medical Society was held at Dublin on Nov. 18 Dr. D. J. Coffey, President of the College of Phy cians, in the chair. The President of the Soci for the coming session is Prof. J. M. O'Connor, w delivered an address on the Physiology of Equi bration. He described, with the aid of the lante the investigations carried out by the late Prof. Mag of Utrecht, and laid stress on the fact that in th important experiments no expensive apparatus h been required, but that the coöperation of sev workers, including skilled surgeons, had been essent An interesting discussion followed the address, speakers being Prof. H. Pringle, Prof. E. P. McLaugh Dr. H. Quinlan, and Dr. E. P. Freeman.

The Approved Societies and Medical Benefit.

The annual meeting of the Approved Soci Association of Ireland was held in Dublin last we The annual report was concerned chiefly with recent report of the Committee of Inquiry on Natio Health Insurance and the Medical Service. In opinion of the Association the time has come fo comprehensive reform of the Poor-law med services. If this cannot be achieved they favou scheme of medical benefit for insured persons a their dependents, with an increase if necessary in weekly contribution, not exceeding 3*d.* a week, if this is not feasible, a scheme of medical benefit insured persons only, with an additional weekly c tribution not exceeding 2*d.*, the Association to consulted in the preparation of the scheme. report shows that there has been an abnormal incre in the benefit payments in 1926 and 1927 as compa with 1925; societies were probably not referring t doubtful cases to the National Health Insura Commission for examination by the medical refe which was provided free of cost. The report a dealt with the inadequacy of the Sanatorium Ben Fund, and with the Departmental Committee's rec mendations on workmen's compensation with reg to the National Health Insurance Acts.

Mr. J. D. Nugent, Secretary of the Ancient Or of Hibernians Approved Society, said that the In national Labour Conference in Geneva last June h in its recommendations, to a large extent adopted system of health insurance in operation in Gr Britain. Ireland was hampered because she had such a system. The Geneva report had recommen

mpulsory sickness insurance for all manual and n-manual workers, and that all insured persons ould be entitled to free medical treatment. The heme as it existed in Ireland did nothing to prevent cure disease, but merely provided sickness benefit members. Doctors were paid for issuing certificates itling recipients to draw benefits, and the more y issued the greater their income.

At the annual dinner held in the evening of the ne day Sir Joseph Glynn, chairman of the National alth Insurance Commission, replying to the toast he Health Services, said that the number of insured sons in the Irish Free State was 456,000.

The Milk Commission.

t is stated that the report of the Milk Commission ointed by the Government of the Irish Free State 1926 has been completed and presented to the vernment. It has not yet been published, but understood to contain, among other recommenda-ns: (1) grading of milk, (2) production under ienic conditions, (3) closer supervision of distribu-e agencies, (4) periodic inspection of dairy farms, veterinary inspection of milch cows, (6) more ngent regulations regarding licensing of dairies distributing centres, and (7) heavier penalties for ach of regulations.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Prohibition and the Public Health.

ROM an analysis of death-rates in the pre-prohibition of 1900–17 and the prohibition and post-influenzal od of 1921–26, Dr. Louis I. Dublin, of the Metro-tan Life Insurance Company, has attempted to uate the broad effect of prohibition on the public th. Taking the death-rate for the whole popula-(U.S. death registration area) he finds that a nward trend in the first period has not been ntained in the second. "If we had only these res," he says, "the most favourable interpretation could give would be that the prohibition amend-t had come into effect at a time of low and ining mortality, and that the new legislation had appreciable effect in still further improving the tality of our people."

somewhat more favourable interpretation is made ible by dissecting the death-rates according to sex, and colour distribution. It is then shown as regards sex and colour there has been during prohibition period an improvement limited to e females. Among men over the age of 35 there on the other hand, been a definite rise in ality. Among children and adolescents the pro-ion period coincides with a marked decline ortality. "One might say," ventures Dr. Dublin, at the facts are entirely consistent with an mption that the conditions of life under the ibition régime have been favourable to these ps; on the other hand, there is no evidence ever of a favourable influence on adult men."

xamining the death-rates further by causes of h Dr. Dublin finds that at children's ages the est improvement has occurred in three groups—dents, diarrhœal diseases, and pneumonia. Among young women the decline noted above is largely able to a decline in the tuberculosis death-rate. these ends the campaigns of popular health ation may have contributed, and a rising standard ving must be held equally responsible. It is y generally agreed among social service workers in the prohibition years there has been a marked ovement in the economic condition of the poorer es. "The economic gains," concludes Dr. Dublin, p us to understand the condition among women children. The character of the present supply of r helps us to understand the lack of improvement h appears in the mortality of men." It is not quite clear whether Dr. Dublin accepts the improved economic condition as a result exclusively of the prohibition amendment. From some remarks early in his paper, presented to an open forum at the annual convention of the American Public Health Association, it would appear that he does not.

In connexion with the present prohibition situation in the States attention is being focused on the congressional election this month in the city of Denver (Colorado). The democratic candidate, Judge White, has openly declared for a modification of the Volstead Act; he is also pledged to a policy "restoring to doctors the right to prescribe liquor in such quantities for medicinal purposes as in their training and experience they find necessary." Judge White's candidature is strenuously opposed by the Anti-Saloon League, the W.C.T.U., and the great majority of the ministers of the Denver churches.

Control of Cancer.

For four years now the Wayne County Medical Society have carried on an annual campaign of education for the control of cancer by early diagnosis. Each year some 2300 citizens present themselves for examination during cancer week at the Detroit Hospital; each year from 15 to 20 per cent. of those examined are found to have cancer or some precancerous condition. The following short table of cancer diagnosed in the last two years shows that the amount of latent cancer in the community is apparently fairly constant.

Cases Diagnosed.

	1926.	*1927.*
Skin	47	43
Breast	18	29
Lip	9	11
Uterus and vulva ..	14	6
Other	6	12
Total	94	101
Precancerous conditions..	282	287

It will be observed that the inaccessible growths are not often diagnosed. Dr. Harry C. Saltzstein, the secretary of the Cancer Committee, points out that in 1925 and 1926 there were 761 recorded deaths from carcinoma of the stomach in Detroit; during this period there were 28 gastric resections for cancer done in all the hospitals of the city, with 15 operative recoveries. More facilities for diagnosis and treatment of cancer are needed, the committee concludes, and more "follow-up" work of the cases diagnosed.

New Medical Centre in New York.

A new medical centre will be formed by the amalgamation of New York Hospital and Cornell University in an institution to be called the New York Hospital Cornell Medical College Association. The building will be situated slightly to the north of the Rockefeller Institute for Medical Research, and the cost is likely to be 15,000,000 dollars (£3,000,000); towards this sum the General Education Board has appropriated 7,500,000 dollars. There will be about 415 public and 75 private beds, and a large out-patient department, whose cost is estimated at 11,000,000 dollars. A distinctive feature of the enterprise is the proposal to relieve the heads of the principal clinical departments from the toil of practice outside the institution; they will be salaried officers giving their whole time to patients, teaching and research. Dr. Robinson, who has been made director of the association, is at present director of Vanderbilt University, where he organised the medical department in 1920. He is a graduate of Johns Hopkins University, and was the first resident physician of the hospital of the Rockefeller Institute for Medical Research. It is interesting to recall that New York Hospital is the second oldest in the United States, having received its charter in 1771. Cornell University Medical College was established in 1898, and has been affiliated with the hospital since 1912.

Correspondence.

"Audi alteram partem."

EPSOM COLLEGE SANATORIUM.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 11th, 1926, you published a letter from the Chairman of Council of Epsom College appealing for financial help from the medical profession to enable the Council to build a new sanatorium and isolation block, which, while providing adequate accommodation for the needs of the College, would at the same time be a model for all other schools to copy. It was also pointed out that the present sanatorium, built many years ago, is uneconomical in working, and its arrangements and accommodation in many ways do not conform to modern hospital requirements, but could by a very moderate outlay be adapted as a school house for from 40 to 45 boys. The existing isolation block is a temporary wooden building, the licence for the use of which expires shortly, making imperative the erection of a permanent building in the near future. Cases of scarlet fever and diphtheria are not dealt with in the isolation block, but are sent direct to the isolation hospital of the local authority.

At Epsom, following the practice of some other public schools, no provision is made in the school houses for the treatment of cases of trivial illness, but all cases, however slight, are treated in the sanatorium. This plan ensures every case being seen by a trained nurse at an early stage, and by the medical officer, who is promptly summoned when necessary; but at the same time it also involves the provision of a larger number of beds than is necessary in those schools which have sick rooms in the school houses.

Experience shows that a well-planned sanatorium, with a properly apportioned number of large and small wards to accommodate 12 per cent. of the boys in the school, meets all reasonable requirements for both infectious and non-infectious cases, provided that if a widespread epidemic of any particular disease occurs, one of the school houses is temporarily converted to hospital purposes.

By adopting the plan which has proved so successful and free from risk in the hands of Dr. Friend, at Christ's Hospital, of housing infectious and non-infectious cases under one roof, but with separate means of access to each class of cases, the architects, Messrs. W. A. Pite, Son and Fairweather, have, at the request of the Council, designed a building which will be in every way a thoroughly up-to-date sanatorium, convenient and economical to work, and which it is estimated can be built for the moderate sum of £26,600.

Taking 400 as the maximum number of boys in the school, provision has been made for 20 beds for the non-infectious cases, and 30 beds for infectious cases, or 50 beds in all, with ample accommodation for the nursing and domestic staff. The details of construction are shown on the plans and dealt with fully in the memorandum accompanying this letter, so need not be further referred to here.

While the school fees paid cover the cost of the ordinary scholars, and the annual subscriptions and donations enable the Council to pay for the foundation scholars, an extraordinary expense, such as the provision of a new sanatorium, cannot be met without the aid of special contributions. It is for this reason that we venture to appeal to your readers to help the Council, and make possible the provision of a sanatorium built and equipped on the most modern lines and worthy of a school, a large proportion of whose scholars are the sons of medical men.

Donations received to date amount to £4207 19*s.* 6*d.*, but until at least £15,000 are in hand it will not be possible to proceed with the actual erection of the buildings.

We are, Sir, yours faithfully,

RAYMOND CRAWFURD,
Chairman of Council of Epsom College.
WILLIAM HALE-WHITE,
Treasurer.
ARNOLD LYNDON,
Chairman, Sanatorium Committee.

ORGANIC HYPNOTICS.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 19th are two letters from well-known manufacturing firms of chemicals relating to organic hypnotics. This subject has been so fully discussed recently at the Royal Society of Medicine,[1] and in the correspondence columns of the *British Medical Journal*,[2] that I do not propose to embark on a further discussion.

The medical profession owes a great debt of gratitude to the discoverers of new drugs of proved therapeutic value. Perhaps the best example is that of salvarsan, which is one of the most valuable therapeutic discoveries of modern times. The manner in which salvarsan was brought before the medical profession by Prof. Ehrlich was a model of perfection. Not only were the uses of the drug clearly pointed out, but the fullest prominence was given to the contra-indications for its use. The dangers of toxic effects were clearly pointed out, and most valuable advice was given as regards that avoidance. In consequence of this, fatalities from poisoning by salvarsan and all drugs have been comparatively few, when one bears in mind the enormous use to which they have been put and the well-known toxicity of the arsenobenzol derivatives. The medical profession owes a great debt of gratitude to Prof. Ehrlich, not only for his wonderful and beneficent discovery, but also for the exemplary care with which he introduced it.

In my paper before the Royal Society of Medicine I stated that the barbituric acid derivatives were perhaps the most commonly used hypnotics, and they have gained this position because of their rapid and certain action. The drugs of this group have a powerful therapeutic action, and if taken in excessive doses may give rise to toxic effects. It is advisable that the early toxic symptoms should be known so that they may be recognised before serious symptoms of poisoning develop. The dangers of possible addiction from their too long-continued use should be realised, since many medical practitioners have had a like experience to myself in meeting with cases of definite addiction from the prolonged daily use of these drugs. Numerous pamphlets have been circulated to the medical profession advertising the barbituric acid group of drugs. None of them, as far as I am aware, contains any reference to the dangers of addiction, and with the exception of those relating to luminal, I have never seen in any of them any warning as regards the danger of overdosage or of the early toxic symptoms to be looked for.

I have no desire to belittle the deservedly recognised therapeutic value of the barbituric acid derivatives. I am strongly of opinion that the firms responsible for the introduction and sale of these drugs should take the medical profession fully into their confidence and give a frank statement of the dangers of overdosage, the early signs of toxic effects, and the care and caution necessary in the use of the drugs. The esteem in which these firms are held by the medical profession would be thereby enhanced, and a feeling of confidence in the use of their drugs ensured. I am quite sure that by so doing there would be no danger of the sale of their remedies suffering in consequence.

I am asked to give statistics as regards fatalities. These are to be found in the Registrar-General's returns. From 1920 to 1926 inclusive there were fatal cases of dial poisoning, and one of didial poisoning

[1] THE LANCET, 1927, i., 1037.
[2] Brit. Med. Jour., 1927, i., 877, 983, and 1125.

ave been recorded. As examples of non-fatal cases may be permitted to quote three out of many in hich I have been consulted.

CASE 1.—Female (Mrs. X), suffering from facial neuralgia. er doctor prescribed one tablet of dialacetin at 9.30 P.M., d one tablet to be repeated at 2 A.M. if necessary. The tient took two tablets of dialacetin, and after a short ne a further two tablets. In addition to this two tablets dial were given by her son. On the following morning 7.30 o'clock, the patient was found to be comatose, the njunctival reflexes were absent, the plantar reflexes gave extensor response. Energetic treatment was adopted rong coffee by nasal tube, colon washes, &c.). At 30 A.M. the patient could be aroused with difficulty, and e plantar reflexes became faintly flexor. At 1 P.M. consciousness had returned, but there was marked slurring of e speech. Headache persisted for 48 hours, and then covery was complete.

CASE 2.—Female aged 50. Acute sciatica on left side for n days. Treated with dial, one tablet three times daily three days. On examination patient was drowsy, speech listinct, tongue furred and could not be protruded, ability to move left arm, retention of urine for 24 hours. ese symptoms were undoubtedly due to dial poisoning, d cleared up in 48 hours after strong coffee, purgatives, and on washes.

CASE 3.—Male aged 34. Previous history of alcoholism. d been under supervision and had taken no alcohol for en weeks. During this period, while under strict medical ervision, had taken three or four tablets of allonal every ht for insomnia. On examination speech thick and listinct, gait ataxic. Diplopia present in the mornings the last few days. This patient was also seen by Sir mes Purves-Stewart, who concurred in the diagnosis of onal poisoning. The symptoms disappeared after the continuance of the drug.

In conclusion, I would like to emphasise the portance of care and caution in the use of the rbituric acid derivatives. They are very valuable erapeutic remedies and, in my opinion, should be ly used under medical supervision, and only taken medical prescription. The medical profession looks guidance and help from the introducers of these w remedies, so that they may be always safely d beneficially used.

I am, Sir, yours faithfully,

Welbeck-street, W., Nov. 26th. W. H. WILLCOX.

PICTORIAL HEALTH PROPAGANDA.

To the Editor of THE LANCET.

SIR,—In an annotation in your last issue entitled alth Education of the Public, attention is called a valuable number of *The World's Health* containing torial propaganda. Some public health workers l be disappointed to read one or two sentences in s annotation—e.g., "Twenty minutes a week voted to the simple things of health in every school uld within ten years do away with the need for st of the posters and pamphlets which Dr. Sands ls with so well." This statement, I suggest, seems strong; while possibly it contains as much truth en looked at from all points of view as any arguents which can be adduced against its verity, on other hand, some people hold the view, perhaps a de one, that many children, rightly or wrongly, ard what they learn in school as something to be gotten as soon as they are released from its bonds, l others think that not a few children regard their sons as dealing with matters entirely divorced m real life. It is not necessary perhaps to pursue s line of thought further; I would pass on to ggest that it is all to the good that essential health quirements should be presented in pictorial form order that such teaching may be absorbed and de part of the belief and life not only of children t, above all, of young and even older adults.

Many interested in pictorial health propaganda ist think that the lesson intended to be inculcated some of the material produced, especially in this ntry and the United States of America, is of so gue and general a character as to be almost useless. e pictorial propaganda produced in Germany has answer the criticisms that it is more suitable for class in physiology than for the general public; a few examples of French pictorial propaganda are, perhaps, more works of art than lessons in hygiene, but all these countries have produced very telling pictures inculcating precepts of the greatest value for the maintenance of health and the prevention of disease. Some of these pictorial lessons are more appropriate to adults than children, anyhow it is only adults who can apply them practically.

The National Association for the Prevention of Tuberculosis has just got out a useful poster showing a woman sewing in her very neat and perhaps too comfortable home—certainly it does not look poverty-stricken—she is a consumptive striving to keep her home and family together instead of going to a sanatorium. The picture presumably tells prospective care committee workers and the public generally that someone should see that such women are placed in such a position as to be able to accept the offer of sanatorium treatment.

I am, Sir, yours faithfully,

C. W. HUTT,
Nov. 28th, 1927. M.O.H. for Holborn.

THE LATE DR. H. P. CHOLMELEY.

To the Editor of THE LANCET.

SIR,—I had just read the obituary of your colleague, Dr. H. P. Cholmeley, in THE LANCET when I had occasion to consult "Prudentius." As I took the volume from my shelves I noticed from an elegant Latin inscription on the fly-leaf that it was the gift of my old Eton and Oxford friend.

We travelled together in Persia and Kurdistan and I well remember his dentistry with a pair of universal forceps on a Kurdish chief and his operation on another Kurd, when Cholmeley and a native doctor, who had studied under the American missionaries, removed a piece of diseased bone from the arm of the grateful Kurd, who presented his surgeons with a pair of socks between them! I believe Cholmeley kept his "first fee" to the day of his death.

Cholmeley, as is said in the obituary notice, was quite unsuited to general practice; he certainly had not the "bedside manner." To a patient who said "What is the matter with me, doctor?" Cholmeley replied: "I don't know, but perhaps I may know to-morrow." I hope your professional readers will forgive a layman for saying that I do not trust many of them at death-beds. But I could trust Cholmeley absolutely, and it was a compact between us that when I was seriously ill I should send for him, because he would tell me when I was going to die—a thing which surely every man has the right to know that he may have time to put a few necessaries together for the journey. Now, alas, my friend has set out before.

Of his literary attainments, his courtesy to all, his tenderness to animals, his sense of humour I could add much to what you have already said. But I will sum him up by saying that to me and to all who knew him well he was like the famous Sir Thomas Browne, of Norwich, an honourable physician and a cultured Christian gentleman.

I am, Sir, yours faithfully,

ATHELSTAN RILEY.

THE ABUSE OF FORCEPS.

To the Editor of THE LANCET.

SIR,—The other day I attended my first confinement case with a new district nurse. As I was about to put on forceps after a very prolonged second stage she remarked: "I suppose the os is nearly fully dilated now, is it, sir?" I half jokingly replied: "You're not accusing me of putting on forceps before the os is fully dilated, are you, nurse?" "Oh, well," she said, "where I've come from one doctor always used to put on forceps when the os was five shillings. He saved me a lot of time." Comment is superfluous.

I am, Sir, yours faithfully,

Nov. 21st, 1927. ASTOUNDED.

THE "TONSIL" QUESTION.

To the Editor of THE LANCET.

SIR,—Mr. Stoker's article in your issue of Nov. 26th is a fair statement of a controversial matter. May I make a few remarks on one subject which interests me. I have had opportunity to treat many cases of chronic otorrhœa at aural clinics of the school medical service. Before coming to a clinic the larger number of these patients have had their tonsils removed and yet otorrhœa exists. A smaller number have had no operation on the throat. This number may be subdivided into those without inflamed tonsils and a few who show signs of definite inflammation. Treatment of the ears of these last is not likely to be successful without operation. Of the large number outside this group, some of whom have had operation and some not, treatment of the ears shows the same result; recurrence of the otorrhœa, in those in whom it has been cured, does not seem to be more frequent in those who have not been submitted to operation than in those who have.

I think that a more or less general practice of removing adenoids and tonsils for chronic otorrhœa arose from the striking results which occasionally followed the operation. If it is permissible to form an opinion it seems to me: (1) from observing those cases of otorrhœa in which an operation has been performed, that in many patients the operation has little effect on otorrhœa; (2) from observing those cases in which the tonsils are not inflamed and in which treatment is confined to the ear, that it is quite unnecessary to remove tonsils and adenoids as a routine measure in chronic otorrhœa.

I do not wish to make an objection to the treatment of tonsils and adenoids based on other indications of their effects, but I think that in a large number of cases of chronic otorrhœa the presence of discharge from the ear is not a reason for removing tonsils and adenoids.

I am, Sir, yours faithfully,

London, W., Nov. 28th, 1927. A. R. FRIEL.

CARLSBAD WATERS.

To the Editor of THE LANCET.

SIR,—It may be of interest to your readers to know that the medicinal waters of Carlsbad—from which resort I have just returned after sampling it in November with enjoyable and satisfactory results—are now admitted into England free of duty. Hitherto the customs authorities were under the impression that the Sprudel, Schlossbrunnen, Mühlbrunnen, and other waters could be used as table beverages. No one could try the experiment with impunity. It is always well to have medical advice before drinking Carlsbad waters, especially away from their source.

I am, Sir, yours faithfully,

ROBERT DONALD.

THE NUTRITIVE VALUE OF BREAD.

To the Editor of THE LANCET.

SIR,—In regard to the interesting and valuable paper of Dr. Cramer and Dr. Mottram on the nutritive value of bread, may I recall the observations made 16 years ago by Martin Flack and myself?[1] We showed then the great superiority of Hovis over white standard and wholemeal bread, owing to the germ included in Hovis. Our rats were bedded on chaff, and fed on bread and water only. On Hovis the rats not only flourished but bred to the third generation. Germ is not only rich in vitamin B, but in vitamin E which is required for breeding.

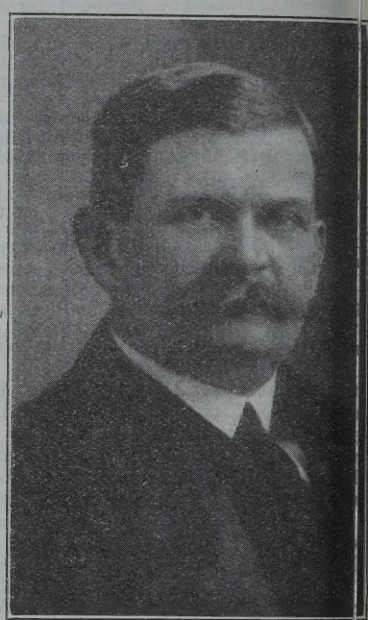
Obituary.

RICHARD HENRY ANGLIN WHITELOCKE M.D. OXF. AND EDIN., M.CH. EDIN., F.R.C.S. ENG

WE announced last week the death of Mr. Ang Whitelocke, the well-known surgeon to the Radcl Infirmary and Litchfield Lecturer on Surgery in University of Oxford.

Richard Henry Anglin Whitelocke was the fou son of Mr. Hugh Whitelocke, of Bulstrode Pa Westmorland, formerly a member of the Execut Council of Jamaica. He was born in 1861, and received his preliminary education at Owens College, Manchester, and from there proceeded as a medical student to the University of Edinburgh. He graduated M.B., B.Ch. in 1884 with honours, and having taken in the same year the diploma of M.R.C.S., he proceeded to hold various resident appointments in Glasgow, Edinburgh, and London. In Glasgow he acted as house surgeon to Sir William Macewen, one of the foremost exponents of Liste surgery at that epoch. In Edinburgh he held an opht mological post, and in London was a clinical assis at Moorfields. For a time he was engaged in hol private classes in anatomy, and this gave a bia the whole of his future career. In 1888 he settle Oxford with a view to practise as an ophthalmolo but on realising there was no opening he ent general practice, but always with the intentio becoming a pure surgeon. He acted as Prof. Art Thomson's first demonstrator in anatomy, worked steadily for the Fellowship of the R College of Surgeons of England, a diploma w he obtained in 1893. His opportunity came six y later when he proved a successful candidate for a on the surgical staff of the Radcliffe Infirmary. speedily became known in Oxford and also over a l county area as a surgeon of great skill and resour



R. H. ANGLIN WHITELOCKE.

His reputation was perhaps specially made connexion with joint injuries and sprains, for Ox provided, through its various athletic activitie fine field for his talents. Alike on the running co or the football field he was in request for all casua among the undergraduates. He acted for m years as consulting surgeon to the University Ru Football Club, and many of his patients now scatt over the face of the earth will read of his death real regret. When, in 1909, he wrote his well-kn book, "Sprains and Allied Injuries of Joints," supplied information of the first assistance to all have to deal with these too often obscure inju The Rontgen rays had at this time been in use over ten years, but no one had pointed out so cle as Whitelocke of what assistance they could b the diagnosis of injuries of the joints. It may

hat before Rontgen's discovery clinical surgery had endered easy the recognition of ordinary dislocaions, but on numerous and slight cases of injury, ommonly called sprains, a flood of light was thrown y the proper employment of the X rays. The value f Whitelocke's treatise lay in the attention which e devoted to the minor injuries of joints, and the eaching was made all the clearer by instruction in he use of massage and of passive exercises, and by n account of bandages and liniments suitable to articular conditions. He followed this work up ith various essays upon football injuries, athletics relation to disease, and the technique of bone perations, and became a recognised authority both Oxford and in London, where he had for a time onsulting rooms. He was appointed Litchfield ecturer on Surgery at the University of Oxford, nd consulting surgeon to the Great Western and ondon and North-Western Railways. In the proedings of the Royal Society of Medicine, where at ne time he served as president of the Section of ediatrics, many useful contributions from his pen ill be found, while in 1914 he contributed to the *ritish Journal of Surgery* two valuable papers spectively on loose bodies in the knee-joint and on slocations of the patella.

During the war Whitelocke had charge, with the nk of Lieut.-Colonel, of the Third Southern General ospital, and made full use of the opportunities then fered for operative surgery, while at the close of ostilities his services were still in demand as a ecialist to the Ministry of Pensions. But that hitelocke was more than a specialist was proved a valuable paper which he read before the Royal ciety of Medicine in 1920 on appendicectomy by a w route. The operation was planned for the removal the vermiform appendix through the right iliac ssa in cases where general exploration of the abdoinal cavity was not called for, that is to say, in ute rather than in chronic cases, and the deviser the operation set out its advantages from the natomical and surgical aspects with remarkable arness. There was much in the paper that invited scussion, but Whitelocke was speaking from the usually strong position of having practised what preached for over 12 years, while he quoted the sults of 843 consecutive operations performed at stages of the disease, whether simple or comicated, and at ages ranging from 3 to 79 years. he mortality-rate was 2·25 per cent. and no hernia weak scars had occurred.

In Oxford Mr. Whitelocke will be deeply missed. om the outset of his career in the city he was a eat supporter of the local medical societies, and is seldom absent from gatherings either of the xford Medical Society or the British Medical sociation, and was always ready to open or take rt in a discussion. He was an honorary Master of ts of Lincoln College, and was also one of the original members of the Oxford Medical Club, club started in Oxford in 1891 with a membership limited to 12, and with the object of reading pers and discussing subjects unconnected with edicine. Only two of the original members remain, of. Arthur Thomson and Dr. William Collier, and om these gatherings Whitelocke was seldom absent. e was a considerable traveller, and it was, in particular, a source of regret to him that ill-health this ar prevented him in joining his surgical colleagues a visit to Madrid.

Mr. Whitelocke had not been in really good health ce the war, though the announcement of his death me as a surprise to many of his friends. He married rbara, eldest daughter of the late Mr. G. L. Reid, I.C.E., of Brighton, and leaves three daughters d three sons, the younger of whom is in medical actice in Oxford.

EDWIN JOHN GURDON, M.R.C.S. ENG.

Dr. E. J. Gurdon, who died on Nov. 19th, came of old Suffolk family and was born at Saxmundham ne 70 years ago. He received his medical education at St. Thomas's Hospital and at Brussels, and in the early eighties went to Australia for the sake of his health, which was always indifferent. He soon had a large consultant practice in Melbourne, but a taste for adventure took him further afield to the Australian goldfields, at first to Condobolin in New South Wales and later to Western Australia. Here his administrative abilities were used on behalf of the Western Australian Medical Service, and his last appointments were as resident magistrate of the well-known pearling towns of Onslow, Shark Bay, and Derby (Kimberley). At the outbreak of war, although there was no special call on him, he came back to England and worked for two years at Winterton in Lincolnshire, thus releasing a younger man for active service. After the Armistice he took a small country practice at Beaumaris in Anglesey, where he was able to live the country life he loved. He was a good shot and a keen sportsman, and kept at work until the day before his death.

Dr. Gurdon's only son died in the war. He leaves a widow and a daughter.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, NOV. 29TH.

Royal Edinburgh Hospital Bill.

The DUKE OF SUTHERLAND, Paymaster-General, moved the first reading of the Royal Edinburgh Hospital for Mental and Nervous Diseases Order Confirmation Bill.

The motion was agreed to.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 23RD.

Production of Vaccine Lymph.

Mr. GROVES asked the Minister of Health what processes were adopted after the collection of the lymph material from calves for vaccine, and what substances were added to it; and why such substances were added.—Sir KINGSLEY WOOD, Parliamentary Secretary to the Ministry of Health, replied: The lymph material collected from calves for vaccine is weighed and reduced to an emulsion with a known weight of a diluent consisting of glycerine, distilled water, and oil of cloves. The diluent is used to bring the lymph material to a suitable consistency, and to get rid of extraneous bacteria.

THURSDAY, NOV. 24TH.

Fraudulent Descriptions of Foodstuffs.

Viscount SANDON asked the Minister of Health whether his attention had been called to the use of fraudulent descriptions in toffee, ice-cream, and other foodstuffs; and whether he would take powers to secure the provision of definitions of food titles in order to eliminate misconception where it existed.—Sir KINGSLEY WOOD replied: If a purchaser demands an article of food under one of the descriptions referred to, it is a question for determination by the court under the Sale of Food and Drugs Acts whether the article sold complies with the description. There is no prescribed standard of composition, and my right hon. friend does not think that the circumstances are such as to justify further legislation.

Cost of Food and Drugs Inspection.

Mr. CECIL WILSON asked the Minister of Health the approximate cost, during each of the last five years, incurred by local authorities in the inspection of foods and drugs, the number of prosecutions for offences, the number of convictions, and the amount of fines imposed; and in how many cases imprisonment had followed conviction.—Sir KINGSLEY WOOD replied: I am circulating a statement of the expenditure and receipts of local authorities in connexion with the work in question during the last five years for which the figures are available. The receipts shown in the statement are principally derived from fines and costs recovered in successful prosecutions. My right hon. friend regrets that the other particulars asked for in the question are not available.

The statement is as follows: Expenditure and receipts of local authorities in England and Wales in connexion

with the prevention of adulteration, &c., of foods and drugs :—

Year.	Expenditure.	Receipts other than from rates.
	£	£
1920–21	108,493	5866
1921–22	113,075	5719
1922–23	107,269	5092
1923–24	109,019	5397
1924–25	114,080	5188

Mr. WILSON : If they are not available now can they be made available for the future ?—Sir KINGSLEY WOOD : I cannot give the hon. Member particulars of the prosecutions and convictions ; I am afraid it is impossible to get them.

Production of Vaccine Lymph.

Mr. GROVES asked the Minister of Health (1) how the carcasses of calves used in connexion with the procurement of vaccine lymph were actually disposed of and (2) what steps were taken in respect to vaccine lymph to ensure that only healthy calves were used.—Sir KINGSLEY WOOD replied : The calves used at the Government lymph establishment are carefully inspected on arrival and are constantly under observation, their temperatures being frequently taken. After the production of lymph the calves are slaughtered and examined by a veterinary expert, and only the lymph from calves certified as healthy is used for vaccination. The carcasses are at the disposal of the person who supplied the calves, and those sold for food are subject to further examination by officers of the local sanitary authorities.

Cost of Health Insurance Administration.

Mr. THOMAS WILLIAMS asked the Minister of Health what was the cost of administering the National Health Insurance funds for the insurance year ended July, 1927, and the percentage this constituted of the total expenditure. —Sir KINGSLEY WOOD replied : The audited accounts of approved societies and insurance committees are made up only in respect of calendar years, and the cost of administration for the insurance (contribution) year ended July, 1927, cannot be stated. For the calendar year 1926 the total cost (including cost of the central administration) was £5,060,000, constituting 13½ per cent. of the total expenditure.

The Smoke Abatement Act.

Mr. ROBERT WILSON asked the Minister of Health whether he could make any statement as to the working of the Smoke Abatement Act.—Sir KINGSLEY WOOD replied : The Act came into force only on July 1st last. I may say, however, that by-laws as to the emission of black smoke have been approved for a number of authorities. Some regional advisory committees have been set up. A Draft Order extending the Alkali Acts has been prepared and considered with representative bodies and the statutory inquiry will be held next month.

The Small-pox Danger.

Sir ARTHUR HOLBROOK asked the Minister of Health whether his attention had been directed to the increase in cases of small-pox during the past few months ; and whether he would consider the introduction of legislation in order to protect the community from this danger.—Sir KINGSLEY WOOD replied : As regards the first part of the question my right hon. friend is aware that small-pox is still prevalent in some parts of the country, but the number of cases notified during recent months is considerably smaller than the numbers notified in the early months of this year. As regards the second part, my right hon. friend is awaiting the report of the Committee on Vaccination, which was appointed last year, before considering the question of further action on this subject.

Slum Clearance Schemes.

Mr. GILLETT asked the Minister of Health the number of persons it was proposed to displace in connexion with the slum clearance scheme in the borough of Finsbury ; and whether provision would be made for rehousing those so displaced within the borough.—Sir KINGSLEY WOOD replied : 205 persons will be displaced in connexion with the Metropolitan Borough of Finsbury (White Horse Alley) Reconstruction Scheme, 1926, and rehousing accommodation for this number is being provided by the borough council in flats which are in course of erection at Mantell-street within the borough.

Mr. ERNEST BROWN asked the Minister of Health what total subsidy had been actually paid by the Government since Jan. 1st, 1919, towards the cost of slum clearances, and in any other way to help directly with the slum problem.—Sir KINGSLEY WOOD replied : The total sum paid on account by Exchequer subsidy towards the cost of slum clearances since April 1st, 1924, is £103,000.

FRIDAY, NOV. 25TH.

Government and Mental Deficiency Bill.

Sir HERBERT CAYZER asked the Prime Minister whether the Government intended to give facilities for the passing into law this session of the Mental Deficiency Bill.—Mr. BALDWIN replied : The Government may be able to find time for this Bill, but the final decision must, of course, depend on the state of business.

MONDAY, NOV. 28TH.

Nursing Homes (Registration) Bill.

Dr. VERNON DAVIES asked the Prime Minister if he would grant facilities before the end of this session for the Nursing Homes (Registration) Bill.—Mr. BALDWIN replied : I can make no promise in regard to time being given to Private Members' Bills, as the final decision must of course depend on the state of business.

Dr. VERNON DAVIES : Is the Prime Minister aware that the differences between the opponents of the Bill are fundamental that unless he uses his power to pass the Bill the grave irregularities and scandals which were disclosed before the Select Committee appointed by this House will go on unchecked to the detriment of the health of the patients in some nursing homes.

No answer was given.

Cost of Small-pox in Durham.

Captain MACMILLAN asked the Minister of Health if he was aware that the recent outbreak of small-pox in the Easington union of the county of Durham had cost the ratepayers a sum of £16,000, equivalent to a rate of 8*d.* in the £, and that in every case it was proved that the persons attacked by the disease had either not been vaccinated at all or had not been vaccinated within the previous 15 years ; Mr. CHAMBERLAIN replied : I have no official information as to the cost of this outbreak. The returns made to my department show that no person under the age of 15 years contracted small-pox who had been vaccinated prior to infection.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 19TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week :—Small-pox, 226 (last week 258) ; scarlet fever, 2320 ; diphtheria, 1509 ; enteric fever, 154 ; pneumonia, 972 ; puerperal fever, 49 ; puerperal pyrexia, 111 ; cerebro-spinal fever, 10 ; acute poliomyelitis, 19 ; acute polio-encephalitis, 4 ; encephalitis lethargica, 31 ; continued fever, 1 ; dysentery, 5 ; ophthalmia neonatorum, 80. There was no case of cholera, plague, or typhus fever notified during the week.

Of the 154 cases of enteric fever 76 were notified from the county of Hertford, where there was a milk-borne outbreak of paratyphoid, 71 being from Hemel Hempstead (U. and R.D.), 4 from Watford (R.D.), and 1 from St. Albans.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 7 (2) from enteric fever, 50 (11) from measles, 5 (0) from scarlet fever, 4 (0) from whooping-cough, 35 (13) from diphtheria, 65 (13) from diarrhœa and enteritis under two years, and 67 (15) from influenza. The figures in parentheses are those for London itself. The deaths from enteric fever outside London occurred in Birmingham 2, Leicester 1, Stockport 1, and Cardiff 1. The number of stillbirths registered during the week was 273 in the great towns, including 54 in London.

THE LATE MR. A. BOLLES LEE.—We are asked to say that copies of the portrait of Mr. A. Bolles Lee, which was published in the *Journal of Pathology and Bacteriology* for last July, may be had from the Editor at 17, Loom-lane, Radlett, Herts.

HOSPITAL BEDS IN THE SHEFFIELD DISTRICT.—On the suggestion of the Ministry of Health a regional conference of all the hospital authorities in the Sheffield district has just been held to consider the availability of beds between Poor-law and voluntary hospitals. It was stated that in the Sheffield area there are 2111 and in the outside districts 1077 patients unable to get beds. The Poor-law institutions have 50 vacant beds, and there are others vacant in the Doncaster Poor-law hospital and in the Worksop area.

Medical News.

UNIVERSITY OF OXFORD.—At a congregation held n Nov. 26th the degree of Doctor of Medicine was conferred n B. G. Scholefield.
